$$\left. \begin{array}{l} v_{2,B} = 1.152 \text{ m}^3/\text{kg} \\ u_{2,B} = 2425.9 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} T_{2,B} = 110.1^\circ\text{C} \\ s_{2,B} = 6.9772 \text{ kJ/kg}\cdot\text{K} \end{array}$$

(b) The total entropy generation during this process is determined by applying the entropy balance on an *extended system* that includes both tanks and their immediate surroundings so that the boundary temperature of the extended system is the temperature of the surroundings at all times. It gives

$$\begin{aligned} & \underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ & -\frac{Q_{\text{out}}}{T_{\text{b,surr}}} + S_{\text{gen}} = \Delta S_A + \Delta S_B \end{aligned}$$

Rearranging and substituting, the total entropy generated during this process is determined to be

$$\begin{aligned} S_{\text{gen}} &= \Delta S_A + \Delta S_B + \frac{Q_{\text{out}}}{T_{\text{b,surr}}} = (m_2 s_2 - m_1 s_1)_A + (m_2 s_2 - m_1 s_1)_B + \frac{Q_{\text{out}}}{T_{\text{b,surr}}} \\ &= \{(0.418)(5.8717) - (0.5403)(5.8717)\} + \{(3.122)(6.9772) - (3)(7.7100)\} + \frac{900 \text{ kJ}}{273 \text{ K}} \\ &= 1.234 \text{ kJ/K} \end{aligned}$$

The work potential wasted is equivalent to the exergy destroyed during a process, which can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (273 \text{ K})(1.234 \text{ kJ/K}) = 337 \text{ kJ}$$

8-112E A cylinder initially filled with helium gas at a specified state is compressed polytropically to a specified temperature and pressure. The actual work consumed and the minimum useful work input needed are to be determined.

Assumptions 1 Helium is an ideal gas with constant specific heats. **2** The cylinder is stationary and thus the kinetic and potential energy changes are negligible. **3** The thermal energy stored in the cylinder itself is negligible. **4** The compression or expansion process is quasi-equilibrium. **5** The environment temperature is 70°F.

Properties The gas constant of helium is $R = 2.6805 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ = 0.4961 Btu/lbm.R (Table A-1E). The specific heats of helium are $c_v = 0.753$ and $c_p = 1.25 \text{ Btu/lbm.R}$ (Table A-2E).

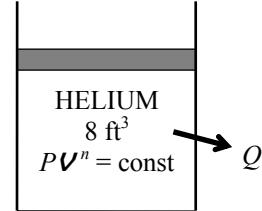

Analysis (a) Helium at specified conditions can be treated as an ideal gas. The mass of helium is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(40 \text{ psia})(8 \text{ ft}^3)}{(2.6805 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(530 \text{ R})} = 0.2252 \text{ lbm}$$

The exponent n and the boundary work for this polytropic process are determined to be

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2} \longrightarrow V_2 = \frac{T_2}{T_1} \frac{P_1}{P_2} V_1 = \frac{(780 \text{ R})(40 \text{ psia})}{(530 \text{ R})(140 \text{ psia})} (8 \text{ ft}^3) = 3.364 \text{ ft}^3$$

$$P_2 V_2^n = P_1 V_1^n \longrightarrow \left(\frac{P_2}{P_1}\right)^n = \left(\frac{V_1}{V_2}\right)^n \longrightarrow \left(\frac{140}{40}\right)^n = \left(\frac{8}{3.364}\right)^n \longrightarrow n = 1.446$$

Then the boundary work for this polytropic process can be determined from

$$W_{b,in} = - \int_1^2 P dV = - \frac{P_2 V_2 - P_1 V_1}{1-n} = - \frac{mR(T_2 - T_1)}{1-n}$$

$$= - \frac{(0.2252 \text{ lbm})(0.4961 \text{ Btu/lbm} \cdot \text{R})(780 - 530)\text{R}}{1 - 1.446} = 62.62 \text{ Btu}$$

Also,

$$W_{surr,in} = -P_0(V_2 - V_1) = -(14.7 \text{ psia})(3.364 - 8)\text{ft}^3 \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) = 12.61 \text{ Btu}$$

Thus,

$$W_{u,in} = W_{b,in} - W_{surr,in} = 62.62 - 12.61 = \mathbf{50.0 \text{ Btu}}$$

(b) We take the helium in the cylinder as the system, which is a closed system. Taking the direction of heat transfer to be from the cylinder, the energy balance for this stationary closed system can be expressed as

$$\underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$-Q_{\text{out}} + W_{\text{b,in}} = \Delta U = m(u_2 - u_1)$$

$$-Q_{\text{out}} = m(u_2 - u_1) - W_{\text{b,in}}$$

$$Q_{\text{out}} = W_{\text{b,in}} - mc_v(T_2 - T_1)$$

Substituting,

$$Q_{\text{out}} = 62.62 \text{ Btu} - (0.2252 \text{ lbm})(0.753 \text{ Btu/lbm} \cdot \text{R})(780 - 530)\text{R} = 20.69 \text{ Btu}$$

The total entropy generation during this process is determined by applying the entropy balance on an *extended system* that includes the cylinder and its immediate surroundings so that the boundary temperature of the extended system is the temperature of the surroundings at all times. It gives

$$\underbrace{S_{in} - S_{out}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$-\frac{Q_{\text{out}}}{T_{b,surr}} + S_{\text{gen}} = \Delta S_{\text{sys}}$$

where the entropy change of helium is

$$\begin{aligned}\Delta S_{\text{sys}} &= \Delta S_{\text{helium}} = m \left(c_{p,\text{avg}} \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) \\ &= (0.2252 \text{ lbm}) \left[(1.25 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{780 \text{ R}}{530 \text{ R}} - (0.4961 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{140 \text{ psia}}{40 \text{ psia}} \right] \\ &= -0.03201 \text{ Btu/R}\end{aligned}$$

Rearranging and substituting, the total entropy generated during this process is determined to be

$$S_{\text{gen}} = \Delta S_{\text{helium}} + \frac{Q_{\text{out}}}{T_0} = (-0.03201 \text{ Btu/R}) + \frac{20.69 \text{ Btu}}{530 \text{ R}} = 0.007022 \text{ Btu/R}$$

The work potential wasted is equivalent to the exergy destroyed during a process, which can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (530 \text{ R})(0.007022 \text{ Btu/R}) = 3.722 \text{ Btu}$$

The minimum work with which this process could be accomplished is the reversible work input, $W_{\text{rev,in}}$ which can be determined directly from

$$W_{\text{rev,in}} = W_{\text{u,in}} - X_{\text{destroyed}} = 50.0 - 3.722 = \mathbf{46.3 \text{ Btu}}$$

Discussion The reversible work input, which represents the minimum work input $W_{\text{rev,in}}$ in this case can be determined from the exergy balance by setting the exergy destruction term equal to zero,

$$\underbrace{X_{\text{in}} - X_{\text{out}}}_{\substack{\text{Net exergy transfer} \\ \text{by heat, work, and mass}}} - \underbrace{X_{\text{destroyed}}}_{\substack{\text{Exergy} \\ \text{destruction}}} \xrightarrow{\text{to (reversible)}} \underbrace{\Delta X_{\text{system}}}_{\substack{\text{Change} \\ \text{in exergy}}} \rightarrow W_{\text{rev,in}} = X_2 - X_1$$

Substituting the closed system exergy relation, the reversible work input during this process is determined to be

$$\begin{aligned}W_{\text{rev}} &= (U_2 - U_1) - T_0(S_2 - S_1) + P_0(V_2 - V_1) \\ &= (0.2252 \text{ lbm})(0.753 \text{ Btu/lbm} \cdot \text{R})(320 - 70)^\circ\text{F} - (530 \text{ R})(-0.03201 \text{ Btu/R}) \\ &\quad + (14.7 \text{ psia})(3.364 - 8)\text{ft}^3 [\text{Btu}/5.4039 \text{ psia} \cdot \text{ft}^3] \\ &= \mathbf{46.7 \text{ Btu}}\end{aligned}$$

The slight difference is due to round-off error.

8-113 Steam expands in a two-stage adiabatic turbine from a specified state to specified pressure. Some steam is extracted at the end of the first stage. The wasted power potential is to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** The turbine is adiabatic and thus heat transfer is negligible. **4** The environment temperature is given to be $T_0 = 25^\circ\text{C}$.

Analysis The wasted power potential is equivalent to the rate of exergy destruction during a process, which can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}}$.

The total rate of entropy generation during this process is determined by taking the entire turbine, which is a control volume, as the system and applying the entropy balance. Noting that this is a steady-flow process and there is no heat transfer,

$$\begin{aligned} \underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} &= \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}}^{\phi 0} = 0 \\ \dot{m}_1 s_1 - \dot{m}_2 s_2 - \dot{m}_3 s_3 + \dot{S}_{\text{gen}} &= 0 \\ \dot{m}_1 s_1 - 0.1\dot{m}_1 s_2 - 0.9\dot{m}_1 s_3 + \dot{S}_{\text{gen}} &= 0 \rightarrow \dot{S}_{\text{gen}} = \dot{m}_1 [0.9s_3 + 0.1s_2 - s_1] \end{aligned}$$

and $X_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = T_0 \dot{m}_1 [0.9s_3 + 0.1s_2 - s_1]$

From the steam tables (Tables A-4 through 6)

$$\begin{cases} P_1 = 9 \text{ MPa} \\ T_1 = 500^\circ\text{C} \end{cases} \left. \begin{array}{l} h_1 = 3387.4 \text{ kJ/kg} \\ s_1 = 6.6603 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\begin{cases} P_2 = 1.4 \text{ MPa} \\ s_{2s} = s_1 \end{cases} \left. \begin{array}{l} h_{2s} = 2882.4 \text{ kJ/kg} \\ s_{2s} = 6.7776 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

and,

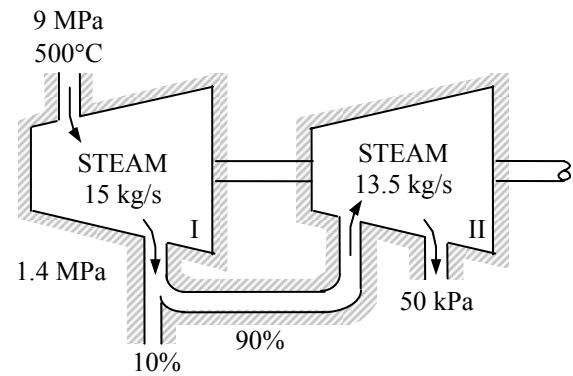

$$\begin{aligned} \eta_T &= \frac{h_1 - h_2}{h_1 - h_{2s}} \longrightarrow h_2 = h_1 - \eta_T (h_1 - h_{2s}) \\ &= 3387.4 - 0.88(3387.4 - 2882.4) \\ &= 2943.0 \text{ kJ/kg} \end{aligned}$$

$$\begin{cases} P_2 = 1.4 \text{ MPa} \\ h_2 = 2943.0 \text{ kJ/kg} \end{cases} \left. \begin{array}{l} s_2 = 6.7776 \text{ kJ/kg}\cdot\text{K} \\ s_2 = 6.7776 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\begin{cases} P_3 = 50 \text{ kPa} \\ s_{3s} = s_1 \end{cases} \left. \begin{array}{l} x_{3s} = \frac{s_{3s} - s_f}{s_{fg}} = \frac{6.6603 - 1.0912}{6.5019} = 0.8565 \\ h_{3s} = h_f + x_{3s} h_{fg} = 340.54 + 0.8565 \times 2304.7 = 2314.6 \text{ kJ/kg} \end{array} \right.$$

$$\begin{aligned} \text{and } \eta_T &= \frac{h_1 - h_3}{h_1 - h_{3s}} \longrightarrow h_3 = h_1 - \eta_T (h_1 - h_{3s}) \\ &= 3387.4 - 0.88(3387.4 - 2314.6) \\ &= 2443.3 \text{ kJ/kg} \end{aligned}$$

$$\begin{cases} P_3 = 50 \text{ kPa} \\ h_3 = 2443.3 \text{ kJ/kg} \end{cases} \left. \begin{array}{l} x_3 = \frac{h_3 - h_f}{h_{fg}} = \frac{2443.3 - 340.54}{2304.7} = 0.9124 \\ s_3 = s_f + x_3 s_{fg} = 1.0912 + 0.9124 \times 6.5019 = 7.0235 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

Substituting, the wasted work potential is determined to be

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(15 \text{ kg/s})(0.9 \times 7.0235 + 0.1 \times 6.7776 - 6.6603) \text{ kJ/kg} = 1514 \text{ kW}$$

8-114 Steam expands in a two-stage adiabatic turbine from a specified state to another specified state. Steam is reheated between the stages. For a given power output, the reversible power output and the rate of exergy destruction are to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** The turbine is adiabatic and thus heat transfer is negligible. **4** The environment temperature is given to be $T_0 = 25^\circ\text{C}$.

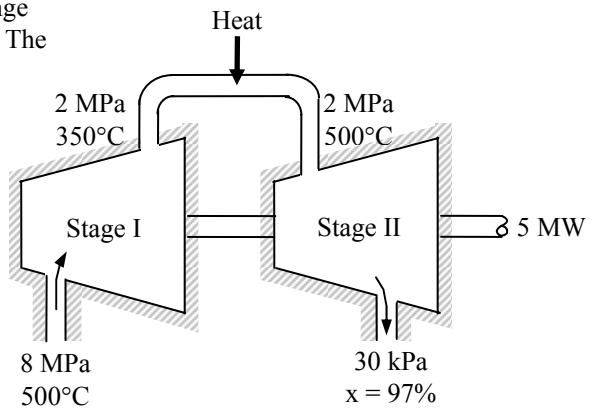

Properties From the steam tables (Tables A-4 through 6)

$$\begin{aligned} P_1 &= 8 \text{ MPa} & h_1 &= 3399.5 \text{ kJ/kg} \\ T_1 &= 500^\circ\text{C} & s_1 &= 6.7266 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_2 &= 2 \text{ MPa} & h_2 &= 3137.7 \text{ kJ/kg} \\ T_2 &= 350^\circ\text{C} & s_2 &= 6.9583 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_3 &= 2 \text{ MPa} & h_3 &= 3468.3 \text{ kJ/kg} \\ T_3 &= 500^\circ\text{C} & s_3 &= 7.4337 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_4 &= 30 \text{ kPa} & h_4 &= h_f + x_4 h_{fg} = 289.27 + 0.97 \times 2335.3 = 2554.5 \text{ kJ/kg} \\ x_4 &= 0.97 & s_4 &= s_f + x_4 s_{fg} = 0.9441 + 0.97 \times 6.8234 = 7.5628 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

Analysis We take the entire turbine, excluding the reheat section, as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}^{\pi 0 (\text{steady})}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 + \dot{m}h_3 = \dot{m}h_2 + \dot{m}h_4 + \dot{W}_{\text{out}}$$

$$\dot{W}_{\text{out}} = \dot{m}[(h_1 - h_2) + (h_3 - h_4)]$$

Substituting, the mass flow rate of the steam is determined from the steady-flow energy equation applied to the actual process,

$$\dot{m} = \frac{\dot{W}_{\text{out}}}{h_1 - h_2 + h_3 - h_4} = \frac{5000 \text{ kJ/s}}{(3399.5 - 3137.7 + 3468.3 - 2554.5) \text{ kJ/kg}} = 4.253 \text{ kg/s}$$

The reversible (or maximum) power output is determined from the rate form of the exergy balance applied on the turbine and setting the exergy destruction term equal to zero,

$$\underbrace{\dot{X}_{\text{in}} - \dot{X}_{\text{out}}}_{\substack{\text{Rate of net exergy transfer} \\ \text{by heat, work, and mass}}} - \underbrace{\dot{X}_{\text{destroyed}}}_{\substack{\text{Rate of exergy} \\ \text{destruction}}} = \underbrace{\Delta \dot{X}_{\text{system}}^{\pi 0 (\text{reversible})}}_{\substack{\text{Rate of change} \\ \text{of exergy}}} = 0$$

$$\dot{X}_{\text{in}} = \dot{X}_{\text{out}}$$

$$\dot{m}\psi_1 + \dot{m}\psi_3 = \dot{m}\psi_2 + \dot{m}\psi_4 + \dot{W}_{\text{rev,out}}$$

$$\dot{W}_{\text{rev,out}} = \dot{m}(\psi_1 - \psi_2) + \dot{m}(\psi_3 - \psi_4)$$

$$= \dot{m}[(h_1 - h_2) + T_0(s_2 - s_1) - \Delta e^{\pi 0} - \Delta p e^{\pi 0}]$$

$$+ \dot{m}[(h_3 - h_4) + T_0(s_4 - s_3) - \Delta e^{\pi 0} - \Delta p e^{\pi 0}]$$

Then the reversible power becomes

$$\begin{aligned} \dot{W}_{\text{rev,out}} &= \dot{m}[h_1 - h_2 + h_3 - h_4 + T_0(s_2 - s_1 + s_4 - s_3)] \\ &= (4.253 \text{ kg/s})[(3399.5 - 3137.7 + 3468.3 - 2554.5) \text{ kJ/kg} \\ &\quad + (298 \text{ K})(6.9583 - 6.7266 + 7.5628 - 7.4337) \text{ kJ/kg}\cdot\text{K}] \\ &= \mathbf{5457 \text{ kW}} \end{aligned}$$

Then the rate of exergy destruction is determined from its definition,

$$\dot{X}_{\text{destroyed}} = \dot{W}_{\text{rev,out}} - \dot{W}_{\text{out}} = 5457 - 5000 = \mathbf{457 \text{ kW}}$$

8-115 An insulated cylinder is divided into two parts. One side of the cylinder contains N₂ gas and the other side contains He gas at different states. The final equilibrium temperature in the cylinder and the wasted work potential are to be determined for the cases of piston being fixed and moving freely.

Assumptions 1 Both N₂ and He are ideal gases with constant specific heats. 2 The energy stored in the container itself is negligible. 3 The cylinder is well-insulated and thus heat transfer is negligible.

Properties The gas constants and the specific heats are $R = 0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.039 \text{ kJ/kg} \cdot ^\circ\text{C}$, and $c_v = 0.743 \text{ kJ/kg} \cdot ^\circ\text{C}$ for N₂, and $R = 2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 5.1926 \text{ kJ/kg} \cdot ^\circ\text{C}$, and $c_v = 3.1156 \text{ kJ/kg} \cdot ^\circ\text{C}$ for He (Tables A-1 and A-2).

Analysis The mass of each gas in the cylinder is

$$m_{N_2} = \left(\frac{P_1 V_1}{RT_1} \right)_{N_2} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(353 \text{ K})} = 4.772 \text{ kg}$$

$$m_{He} = \left(\frac{P_1 V_1}{RT_1} \right)_{He} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})} = 0.8079 \text{ kg}$$

N ₂	He
1 m ³	1 m ³
500 kPa	500 kPa
80°C	25°C

Taking the entire contents of the cylinder as our system, the 1st law relation can be written as

$$\begin{aligned} \underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} &= \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ 0 &= \Delta U = (\Delta U)_{N_2} + (\Delta U)_{He} \\ 0 &= [mc_v(T_2 - T_1)]_{N_2} + [mc_v(T_2 - T_1)]_{He} \end{aligned}$$

Substituting,

$$(4.772 \text{ kg})(0.743 \text{ kJ/kg} \cdot ^\circ\text{C})(T_f - 80)^\circ\text{C} + (0.8079 \text{ kg})(3.1156 \text{ kJ/kg} \cdot ^\circ\text{C})(T_f - 25)^\circ\text{C} = 0$$

It gives

$$T_f = 57.2^\circ\text{C}$$

where T_f is the final equilibrium temperature in the cylinder.

The answer would be the **same** if the piston were not free to move since it would effect only pressure, and not the specific heats.

(b) We take the entire cylinder as our system, which is a closed system. Noting that the cylinder is well-insulated and thus there is no heat transfer, the entropy balance for this closed system can be expressed as

$$\begin{aligned} \underbrace{S_{in} - S_{out}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{gen}}_{\substack{\text{Entropy} \\ \text{generation}}} &= \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ 0 + S_{gen} &= \Delta S_{N_2} + \Delta S_{He} \end{aligned}$$

But first we determine the final pressure in the cylinder:

$$\begin{aligned} N_{\text{total}} &= N_{N_2} + N_{He} = \left(\frac{m}{M} \right)_{N_2} + \left(\frac{m}{M} \right)_{He} = \frac{4.772 \text{ kg}}{28 \text{ kg/kmol}} + \frac{0.8079 \text{ kg}}{4 \text{ kg/kmol}} = 0.3724 \text{ kmol} \\ P_2 &= \frac{N_{\text{total}} R_u T}{V_{\text{total}}} = \frac{(0.3724 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(330.2 \text{ K})}{2 \text{ m}^3} = 511.1 \text{ kPa} \end{aligned}$$

Then,

$$\begin{aligned} \Delta S_{N_2} &= m \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{N_2} \\ &= (4.772 \text{ kg}) \left[(1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{330.2 \text{ K}}{353 \text{ K}} - (0.2968 \text{ kJ/kg} \cdot \text{K}) \ln \frac{511.1 \text{ kPa}}{500 \text{ kPa}} \right] = -0.3628 \text{ kJ/K} \end{aligned}$$

$$\begin{aligned}\Delta S_{\text{He}} &= m \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{\text{He}} \\ &= (0.8079 \text{ kg}) \left[(5.1926 \text{ kJ/kg}\cdot\text{K}) \ln \frac{330.2 \text{ K}}{298 \text{ K}} - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln \frac{511.1 \text{ kPa}}{500 \text{ kPa}} \right] = 0.3931 \text{ kJ/K}\end{aligned}$$

$$S_{\text{gen}} = \Delta S_{\text{N}_2} + \Delta S_{\text{He}} = -0.3628 + 0.3931 = 0.0303 \text{ kJ/K}$$

The wasted work potential is equivalent to the exergy destroyed during a process, and it can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.0303 \text{ kJ/K}) = \mathbf{9.03 \text{ kJ}}$$

If the piston were not free to move, we would still have $T_2 = 330.2 \text{ K}$ but the volume of each gas would remain constant in this case:

$$\begin{aligned}\Delta S_{\text{N}_2} &= m \left(c_v \ln \frac{T_2}{T_1} - R \ln \frac{\mathcal{V}_2^{\phi_0}}{\mathcal{V}_1} \right)_{\text{N}_2} = (4.772 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K}) \ln \frac{330.2 \text{ K}}{353 \text{ K}} = -0.2371 \text{ kJ/K} \\ \Delta S_{\text{He}} &= m \left(c_v \ln \frac{T_2}{T_1} - R \ln \frac{\mathcal{V}_2^{\phi_0}}{\mathcal{V}_1} \right)_{\text{He}} = (0.8079 \text{ kg})(3.1156 \text{ kJ/kg}\cdot\text{K}) \ln \frac{330.2 \text{ K}}{298 \text{ K}} = 0.258 \text{ kJ/K}\end{aligned}$$

$$S_{\text{gen}} = \Delta S_{\text{N}_2} + \Delta S_{\text{He}} = -0.2371 + 0.258 = 0.02089 \text{ kJ/K}$$

and

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.02089 \text{ kJ/K}) = \mathbf{6.23 \text{ kJ}}$$

8-116 An insulated cylinder is divided into two parts. One side of the cylinder contains N₂ gas and the other side contains He gas at different states. The final equilibrium temperature in the cylinder and the wasted work potential are to be determined for the cases of piston being fixed and moving freely.

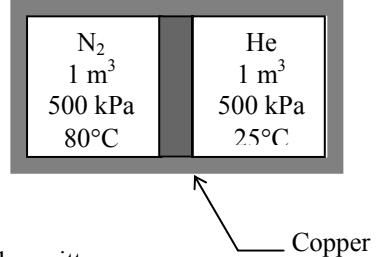

Assumptions 1 Both N₂ and He are ideal gases with constant specific heats. 2 The energy stored in the container itself, except the piston, is negligible. 3 The cylinder is well-insulated and thus heat transfer is negligible. 4 Initially, the piston is at the average temperature of the two gases.

Properties The gas constants and the specific heats are $R = 0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.039 \text{ kJ/kg}\cdot\text{C}$, and $c_v = 0.743 \text{ kJ/kg}\cdot\text{C}$ for N₂, and $R = 2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{C}$, and $c_v = 3.1156 \text{ kJ/kg}\cdot\text{C}$ for He (Tables A-1 and A-2). The specific heat of copper piston is $c = 0.386 \text{ kJ/kg}\cdot\text{C}$ (Table A-3).

Analysis The mass of each gas in the cylinder is

$$m_{N_2} = \left(\frac{P_1 V_1}{RT_1} \right)_{N_2} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(353 \text{ K})} = 4.772 \text{ kg}$$

$$m_{He} = \left(\frac{P_1 V_1}{RT_1} \right)_{He} = \frac{(500 \text{ kPa})(1 \text{ m}^3)}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(353 \text{ K})} = 0.8079 \text{ kg}$$

Taking the entire contents of the cylinder as our system, the 1st law relation can be written as

$$\underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$0 = \Delta U = (\Delta U)_{N_2} + (\Delta U)_{He} + (\Delta U)_{Cu}$$

$$0 = [mc_v(T_2 - T_1)]_{N_2} + [mc_v(T_2 - T_1)]_{He} + [mc(T_2 - T_1)]_{Cu}$$

where

$$T_{1,Cu} = (80 + 25)/2 = 52.5^\circ\text{C}$$

Substituting,

$$(4.772 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{C})(T_f - 80)^\circ\text{C} + (0.8079 \text{ kg})(3.1156 \text{ kJ/kg}\cdot\text{C})(T_f - 25)^\circ\text{C} + (5.0 \text{ kg})(0.386 \text{ kJ/kg}\cdot\text{C})(T_f - 52.5)^\circ\text{C} = 0$$

It gives

$$T_f = 56.0^\circ\text{C}$$

where T_f is the final equilibrium temperature in the cylinder.

The answer would be the **same** if the piston were not free to move since it would effect only pressure, and not the specific heats.

(b) We take the entire cylinder as our system, which is a closed system. Noting that the cylinder is well-insulated and thus there is no heat transfer, the entropy balance for this closed system can be expressed as

$$\underbrace{S_{in} - S_{out}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{gen}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$0 + S_{gen} = \Delta S_{N_2} + \Delta S_{He} + \Delta S_{piston}$$

But first we determine the final pressure in the cylinder:

$$N_{\text{total}} = N_{N_2} + N_{He} = \left(\frac{m}{M} \right)_{N_2} + \left(\frac{m}{M} \right)_{He} = \frac{4.772 \text{ kg}}{28 \text{ kg/kmol}} + \frac{0.8079 \text{ kg}}{4 \text{ kg/kmol}} = 0.3724 \text{ kmol}$$

$$P_2 = \frac{N_{\text{total}} R_u T}{V_{\text{total}}} = \frac{(0.3724 \text{ kmol})(8.314 \text{ kPa}\cdot\text{m}^3/\text{kmol}\cdot\text{K})(329 \text{ K})}{2 \text{ m}^3} = 509.4 \text{ kPa}$$

Then,

$$\begin{aligned}\Delta S_{N_2} &= m \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{N_2} \\ &= (4.772 \text{ kg}) \left[(1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} - (0.2968 \text{ kJ/kg} \cdot \text{K}) \ln \frac{509.4 \text{ kPa}}{500 \text{ kPa}} \right] = -0.3749 \text{ kJ/K} \\ \Delta S_{He} &= m \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{He} \\ &= (0.8079 \text{ kg}) \left[(5.1926 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} - (2.0769 \text{ kJ/kg} \cdot \text{K}) \ln \frac{509.4 \text{ kPa}}{500 \text{ kPa}} \right] = 0.3845 \text{ kJ/K} \\ \Delta S_{\text{piston}} &= \left(mc \ln \frac{T_2}{T_1} \right)_{\text{piston}} = (5 \text{ kg})(0.386 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{325.5 \text{ K}} = 0.021 \text{ kJ/K} \\ S_{\text{gen}} &= \Delta S_{N_2} + \Delta S_{He} + \Delta S_{\text{piston}} = -0.3749 + 0.3845 + 0.021 = 0.03047 \text{ kJ/K}\end{aligned}$$

The wasted work potential is equivalent to the exergy destroyed during a process, and it can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.03047 \text{ kJ/K}) = \mathbf{9.08 \text{ kJ}}$$

If the piston were not free to move, we would still have $T_2 = 330.2 \text{ K}$ but the volume of each gas would remain constant in this case:

$$\begin{aligned}\Delta S_{N_2} &= m \left(c_v \ln \frac{T_2}{T_1} - R \ln \frac{\mathcal{V}_2^{\phi 0}}{\mathcal{V}_1^{\phi 0}} \right)_{N_2} = (4.772 \text{ kg})(0.743 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} = -0.2492 \text{ kJ/K} \\ \Delta S_{He} &= m \left(c_v \ln \frac{T_2}{T_1} - R \ln \frac{\mathcal{V}_2^{\phi 0}}{\mathcal{V}_1^{\phi 0}} \right)_{He} = (0.8079 \text{ kg})(3.1156 \text{ kJ/kg} \cdot \text{K}) \ln \frac{329 \text{ K}}{353 \text{ K}} = 0.2494 \text{ kJ/K} \\ S_{\text{gen}} &= \Delta S_{N_2} + \Delta S_{He} + \Delta S_{\text{piston}} = -0.2492 + 0.2494 + 0.021 = 0.02104 \text{ kJ/K}\end{aligned}$$

and

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.02104 \text{ kJ/K}) = \mathbf{6.27 \text{ kJ}}$$

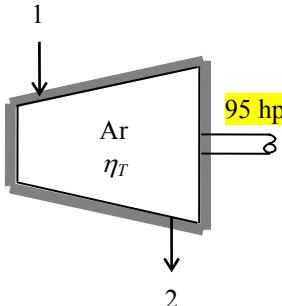

8-117E Argon enters an adiabatic turbine at a specified state with a specified mass flow rate, and leaves at a specified pressure. The isentropic and second-law efficiencies of the turbine are to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** The device is adiabatic and thus heat transfer is negligible. **4** Argon is an ideal gas with constant specific heats.

Properties The specific heat ratio of argon is $k = 1.667$. The constant pressure specific heat of argon is $c_p = 0.1253 \text{ Btu/lbm.R}$. The gas constant is $R = 0.04971 \text{ Btu/lbm.R}$ (Table A-2E).

Analysis There is only one inlet and one exit, and thus $\dot{m}_1 = \dot{m}_2 = \dot{m}$. We take the isentropic turbine as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\begin{aligned} \underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} &= \underbrace{\Delta \dot{E}_{\text{system}}^{\text{20 (steady)}}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{m}h_1 &= \dot{W}_{s,\text{out}} + \dot{m}h_{2s} \quad (\text{since } \dot{Q} \equiv \Delta \text{ke} \equiv \Delta \text{pe} \equiv 0) \\ \dot{W}_{s,\text{out}} &= \dot{m}(h_1 - h_{2s}) \end{aligned}$$

From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_{2s}}{P_1} \right)^{(k-1)/k} = (1960 \text{ R}) \left(\frac{30 \text{ psia}}{200 \text{ psia}} \right)^{0.667/1.667} = 917.5 \text{ R}$$

Then the power output of the isentropic turbine becomes

$$\dot{W}_{s,\text{out}} = \dot{m}c_p(T_1 - T_{2s}) = (40 \text{ lbm/min})(0.1253 \text{ Btu/lbm.R})(1960 - 917.5) \text{ R} \left(\frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) = 123.2 \text{ hp}$$

Then the isentropic efficiency of the turbine is determined from

$$\eta_T = \frac{\dot{W}_{a,\text{out}}}{\dot{W}_{s,\text{out}}} = \frac{95 \text{ hp}}{123.2 \text{ hp}} = 0.771 = 77.1\%$$

(b) Using the steady-flow energy balance relation $\dot{W}_{a,\text{out}} = \dot{m}c_p(T_1 - T_2)$ above, the actual turbine exit temperature is determined to be

$$T_2 = T_1 - \frac{\dot{W}_{a,\text{out}}}{\dot{m}c_p} = 1500 - \frac{95 \text{ hp}}{(40 \text{ lbm/min})(0.1253 \text{ Btu/lbm.R})} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) = 696.1^\circ\text{F} = 1156.1 \text{ R}$$

The entropy generation during this process can be determined from an entropy balance on the turbine,

$$\begin{aligned} \underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\substack{\text{Rate of net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{\dot{S}_{\text{gen}}}_{\substack{\text{Rate of entropy} \\ \text{generation}}} &= \underbrace{\Delta \dot{S}_{\text{system}}^{\text{20}}}_{\substack{\text{Rate of change} \\ \text{of entropy}}} = 0 \\ \dot{m}s_1 - \dot{m}s_2 + \dot{S}_{\text{gen}} &= 0 \\ \dot{S}_{\text{gen}} &= \dot{m}(s_2 - s_1) \end{aligned}$$

where

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (0.1253 \text{ Btu/lbm.R}) \ln \frac{1156.1 \text{ R}}{1960 \text{ R}} - (0.04971 \text{ Btu/lbm.R}) \ln \frac{30 \text{ psia}}{200 \text{ psia}} \\ &= 0.02816 \text{ Btu/lbm.R} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition
 $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$\begin{aligned}\dot{X}_{\text{destroyed}} &= T_0 \dot{S}_{\text{gen}} = \dot{m} T_0 (s_2 - s_1) \\ &= (40 \text{ lbm/min})(537 \text{ R})(0.02816 \text{ Btu/lbm} \cdot \text{R}) \left(\frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) \\ &= 14.3 \text{ hp}\end{aligned}$$

Then the reversible power and second-law efficiency become

$$\dot{W}_{\text{rev,out}} = \dot{W}_{a,\text{out}} + \dot{X}_{\text{destroyed}} = 95 + 14.3 = 109.3 \text{ hp}$$

and

$$\eta_{II} = \frac{\dot{W}_{a,\text{out}}}{\dot{W}_{\text{rev,out}}} = \frac{95 \text{ hp}}{109.3 \text{ hp}} = \mathbf{86.9\%}$$

8-118 The feedwater of a steam power plant is preheated using steam extracted from the turbine. The ratio of the mass flow rates of the extracted steam and the feedwater are to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** Heat loss from the device to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid.

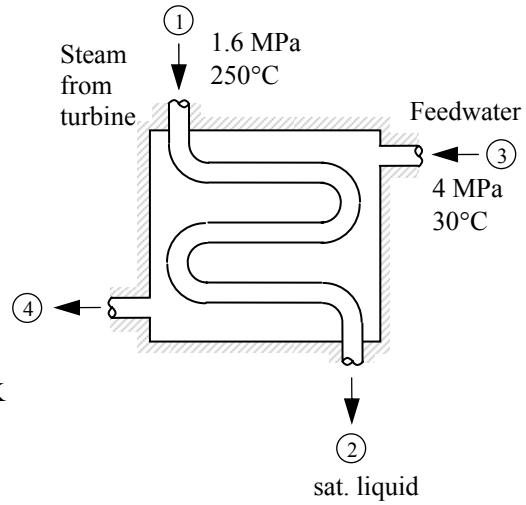

Properties The properties of steam and feedwater are (Tables A-4 through A-6)

$$\begin{cases} P_1 = 1.6 \text{ MPa} \\ T_1 = 250^\circ\text{C} \end{cases} \quad \begin{cases} h_1 = 2919.9 \text{ kJ/kg} \\ s_1 = 6.6753 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_2 = 1.6 \text{ MPa} \\ \text{sat. liquid} \end{cases} \quad \begin{cases} h_2 = h_{f@1.6 \text{ MPa}} = 858.44 \text{ kJ/kg} \\ s_2 = s_{f@1.6 \text{ MPa}} = 2.3435 \text{ kJ/kg} \cdot \text{K} \\ T_2 = 201.4^\circ\text{C} \end{cases}$$

$$\begin{cases} P_3 = 4 \text{ MPa} \\ T_3 = 30^\circ\text{C} \end{cases} \quad \begin{cases} h_3 \approx h_{f@30^\circ\text{C}} = 129.37 \text{ kJ/kg} \\ s_3 \approx s_{f@30^\circ\text{C}} = 0.4355 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 4 \text{ MPa} \\ T_4 = T_2 - 10^\circ\text{C} \approx 191.4^\circ\text{C} \end{cases} \quad \begin{cases} h_4 \approx h_{f@191.4^\circ\text{C}} = 814.78 \text{ kJ/kg} \\ s_4 \approx s_{f@191.4^\circ\text{C}} = 2.2446 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

Analysis (a) We take the heat exchanger as the system, which is a control volume. The mass and energy balances for this steady-flow system can be expressed in the rate form as follows:

Mass balance (for each fluid stream):

$$\dot{m}_{\text{in}} - \dot{m}_{\text{out}} = \Delta\dot{m}_{\text{system}}^{\text{st0 (steady)}} = 0 \rightarrow \dot{m}_{\text{in}} = \dot{m}_{\text{out}} \rightarrow \dot{m}_1 = \dot{m}_2 = \dot{m}_s \quad \text{and} \quad \dot{m}_3 = \dot{m}_4 = \dot{m}_{fw}$$

Energy balance (for the heat exchanger):

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer}} = \underbrace{\Delta\dot{E}_{\text{system}}^{\text{st0 (steady)}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} = 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 = \dot{m}_2 h_2 + \dot{m}_4 h_4 \quad (\text{since } \dot{Q} = \dot{W} = \Delta\text{ke} \equiv \Delta\text{pe} \equiv 0)$$

$$\text{Combining the two,} \quad \dot{m}_s (h_2 - h_1) = \dot{m}_{fw} (h_3 - h_4)$$

Dividing by \dot{m}_{fw} and substituting,

$$\frac{\dot{m}_s}{\dot{m}_{fw}} = \frac{h_3 - h_4}{h_2 - h_1} = \frac{(129.37 - 814.78) \text{ kJ/kg}}{(858.44 - 2919.9) \text{ kJ/kg}} = \mathbf{0.3325}$$

(b) The entropy generation during this process per unit mass of feedwater can be determined from an entropy balance on the feedwater heater expressed in the rate form as

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta\dot{S}_{\text{system}}^{\text{st0}}}_{\text{Rate of change of entropy}} = 0$$

$$\dot{m}_1 s_1 - \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_4 s_4 + \dot{S}_{\text{gen}} = 0$$

$$\dot{m}_s (s_1 - s_2) + \dot{m}_{fw} (s_3 - s_4) + \dot{S}_{\text{gen}} = 0$$

$$\frac{\dot{S}_{\text{gen}}}{\dot{m}_{fw}} = \frac{\dot{m}_s}{\dot{m}_{fw}} (s_2 - s_1) + (s_4 - s_3) = (0.3325)(2.3435 - 6.6753) + (2.2446 - 0.4355) = 0.3688 \text{ kJ/K} \cdot \text{kg fw}$$

Noting that this process involves no actual work, the reversible work and exergy destruction become equivalent since

$$X_{\text{destroyed}} = W_{\text{rev,out}} - W_{\text{act,out}} \rightarrow W_{\text{rev,out}} = X_{\text{destroyed}}.$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(0.3688 \text{ kJ/K} \cdot \text{kg fw}) = \mathbf{109.9 \text{ kJ/kg feedwater}}$$

8-119 Problem 8-118 is reconsidered. The effect of the state of the steam at the inlet of the feedwater heater on the ratio of mass flow rates and the reversible power is to be investigated.

Analysis Using EES, the problem is solved as follows:

```

"Input Data"
"Steam (let st=steam data):"
Fluid$='Steam_IAPWS'
T_st[1]=250 [C]
{P_st[1]=1600 [kPa]}
P_st[2] = P_st[1]
x_st[2]=0 "saturated liquid, quality = 0%"
T_st[2]=temperature(steam, P=P_st[2], x=x_st[2])

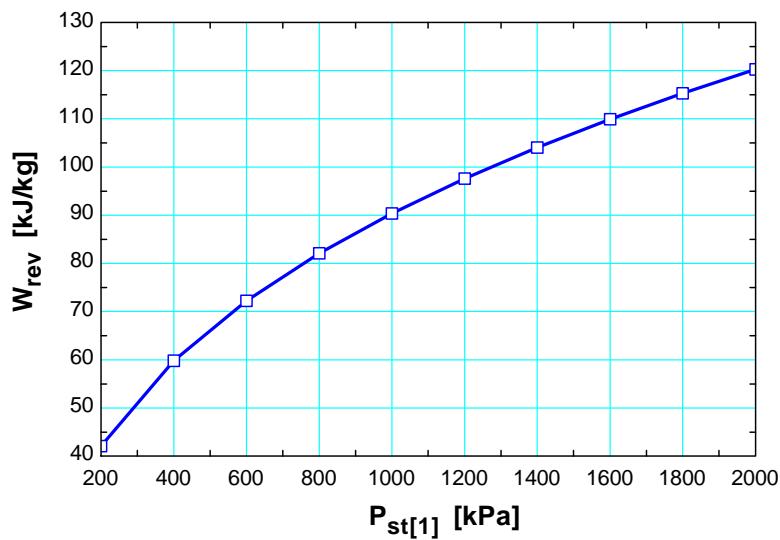

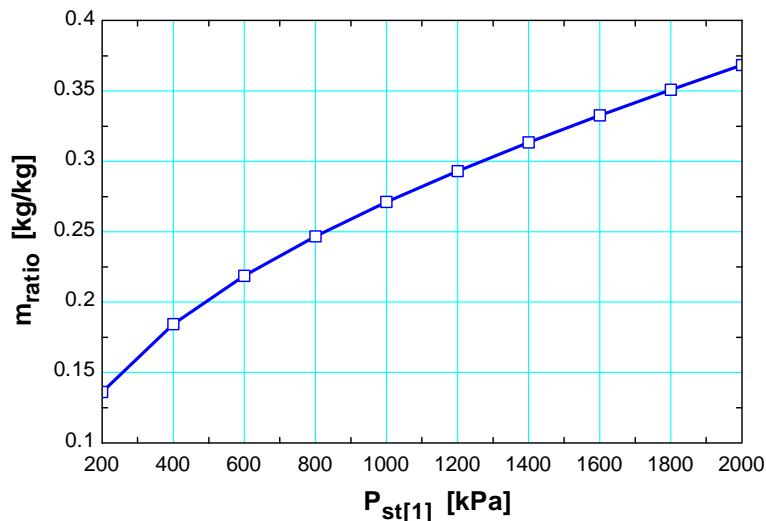

"Feedwater (let fw=feedwater data):"
T_fw[1]=30 [C]
P_fw[1]=4000 [kPa]
P_fw[2]=P_fw[1] "assume no pressure drop for the feedwater"
T_fw[2]=T_st[2]-10

"Surroundings:"
T_o = 25 [C]
P_o = 100 [kPa] "Assumed value for the surroundings pressure"

8-120 A 1-ton (1000 kg) of water is to be cooled in a tank by pouring ice into it. The final equilibrium temperature in the tank and the exergy destruction are to be determined.

Assumptions 1 Thermal properties of the ice and water are constant. 2 Heat transfer to the water tank is negligible. 3 There is no stirring by hand or a mechanical device (it will add energy).

Properties The specific heat of water at room temperature is $c = 4.18 \text{ kJ/kg}\cdot\text{°C}$, and the specific heat of ice at about 0°C is $c = 2.11 \text{ kJ/kg}\cdot\text{°C}$ (Table A-3). The melting temperature and the heat of fusion of ice at 1 atm are 0°C and 333.7 kJ/kg .

Analysis (a) We take the ice and the water as the system, and disregard any heat transfer between the system and the surroundings. Then the energy balance for this process can be written as

$$\begin{aligned} \underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} &= \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ 0 &= \Delta U \\ 0 &= \Delta U_{\text{ice}} + \Delta U_{\text{water}} \\ [mc(0^\circ\text{C} - T_1)_{\text{solid}} + mh_{if} + mc(T_2 - 0^\circ\text{C})_{\text{liquid}}]_{\text{ice}} + [mc(T_2 - T_1)]_{\text{water}} &= 0 \end{aligned}$$

Substituting,

$$\begin{aligned} (80 \text{ kg})\{(2.11 \text{ kJ/kg}\cdot\text{°C})(0 - (-5))^\circ\text{C} + 333.7 \text{ kJ/kg} + (4.18 \text{ kJ/kg}\cdot\text{°C})(T_2 - 0)^\circ\text{C}\} \\ +(1000 \text{ kg})(4.18 \text{ kJ/kg}\cdot\text{°C})(T_2 - 20)^\circ\text{C} = 0 \end{aligned}$$

It gives $T_2 = 12.42^\circ\text{C}$

which is the final equilibrium temperature in the tank.

(b) We take the ice and the water as our system, which is a closed system. Considering that the tank is well-insulated and thus there is no heat transfer, the entropy balance for this closed system can be expressed as

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} &= \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ 0 + S_{\text{gen}} &= \Delta S_{\text{ice}} + \Delta S_{\text{water}} \end{aligned}$$

where

$$\begin{aligned} \Delta S_{\text{water}} &= \left(mc \ln \frac{T_2}{T_1} \right)_{\text{water}} = (1000 \text{ kg})(4.18 \text{ kJ/kg}\cdot\text{K}) \ln \frac{285.42 \text{ K}}{293 \text{ K}} = -109.590 \text{ kJ/K} \\ \Delta S_{\text{ice}} &= (\Delta S_{\text{solid}} + \Delta S_{\text{melting}} + \Delta S_{\text{liquid}})_{\text{ice}} \\ &= \left(\left(mc \ln \frac{T_{\text{melting}}}{T_1} \right)_{\text{solid}} + \frac{mh_{ig}}{T_{\text{melting}}} + \left(mc \ln \frac{T_2}{T_1} \right)_{\text{liquid}} \right)_{\text{ice}} \\ &= (80 \text{ kg}) \left((2.11 \text{ kJ/kg}\cdot\text{K}) \ln \frac{273 \text{ K}}{268 \text{ K}} + \frac{333.7 \text{ kJ/kg}}{273 \text{ K}} + (4.18 \text{ kJ/kg}\cdot\text{K}) \ln \frac{285.42 \text{ K}}{273 \text{ K}} \right) \\ &= 115.783 \text{ kJ/K} \end{aligned}$$

Then, $S_{\text{gen}} = \Delta S_{\text{water}} + \Delta S_{\text{ice}} = -109.590 + 115.783 = 6.193 \text{ kJ/K}$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(6.193 \text{ kJ/K}) = 1815 \text{ kJ}$$

8-121 One ton of liquid water at 65°C is brought into a room. The final equilibrium temperature in the room and the entropy generated are to be determined.

Assumptions 1 The room is well insulated and well sealed. **2** The thermal properties of water and air are constant at room temperature. **3** The system is stationary and thus the kinetic and potential energy changes are zero. **4** There are no work interactions involved.

Properties The gas constant of air is $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ (Table A-1). The constant volume specific heat of water at room temperature is $c_v = 0.718 \text{ kJ/kg} \cdot ^\circ\text{C}$ (Table A-2). The specific heat of water at room temperature is $c = 4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$ (Table A-3).

Analysis The volume and the mass of the air in the room are

$$V = 3 \times 4 \times 7 = 84 \text{ m}^3$$

$$m_{\text{air}} = \frac{P_1 V}{R T_1} = \frac{(100 \text{ kPa})(84 \text{ m}^3)}{(0.2870 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(289 \text{ K})} = 101.3 \text{ kg}$$

Taking the contents of the room, including the water, as our system, the energy balance can be written as

$$\begin{aligned} \underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} &= \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ 0 &= \Delta U = (\Delta U)_{\text{water}} + (\Delta U)_{\text{air}} \end{aligned}$$

$$\text{or } [mc(T_2 - T_1)]_{\text{water}} + [mc_v(T_2 - T_1)]_{\text{air}} = 0$$

$$\text{Substituting, } (1000 \text{ kg})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(T_f - 65)^\circ\text{C} + (101.3 \text{ kg})(0.718 \text{ kJ/kg} \cdot ^\circ\text{C})(T_f - 16)^\circ\text{C} = 0$$

It gives the final equilibrium temperature in the room to be

$$T_f = 64.2^\circ\text{C}$$

(b) We again take the room and the water in it as the system, which is a closed system. Considering that the system is well-insulated and no mass is entering and leaving, the entropy balance for this system can be expressed as

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} &= \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ 0 + S_{\text{gen}} &= \Delta S_{\text{air}} + \Delta S_{\text{water}} \end{aligned}$$

where

$$\Delta S_{\text{air}} = mc_v \ln \frac{T_2}{T_1} + mR \ln \frac{V_2}{V_1} = (101.3 \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K}) \ln \frac{337.2 \text{ K}}{289 \text{ K}} = 11.21 \text{ kJ/K}$$

$$\Delta S_{\text{water}} = mc \ln \frac{T_2}{T_1} = (1000 \text{ kg})(4.18 \text{ kJ/kg} \cdot \text{K}) \ln \frac{337.2 \text{ K}}{338 \text{ K}} = -10.37 \text{ kJ/K}$$

Substituting, the entropy generation is determined to be

$$S_{\text{gen}} = 11.21 - 10.37 = 0.834 \text{ kJ/K}$$

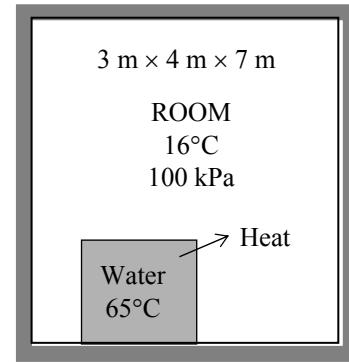

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition

$$X_{\text{destroyed}} = T_0 S_{\text{gen}},$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (283 \text{ K})(0.834 \text{ kJ/K}) = 236 \text{ kJ}$$

(c) The work potential (the maximum amount of work that can be produced) during a process is simply the reversible work output. Noting that the actual work for this process is zero, it becomes

$$X_{\text{destroyed}} = W_{\text{rev,out}} - W_{\text{act,out}} \rightarrow W_{\text{rev,out}} = X_{\text{destroyed}} = 236 \text{ kJ}$$

8-122 An evacuated bottle is surrounded by atmospheric air. A valve is opened, and air is allowed to fill the bottle. The amount of heat transfer through the wall of the bottle when thermal and mechanical equilibrium is established and the amount of exergy destroyed are to be determined.

Assumptions 1 This is an unsteady process since the conditions within the device are changing during the process, but it can be analyzed as a uniform-flow process since the state of fluid at the inlet remains constant. **2** Air is an ideal gas. **3** Kinetic and potential energies are negligible. **4** There are no work interactions involved. **5** The direction of heat transfer is to the air in the bottle (will be verified).

Properties The gas constant of air is $0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ (Table A-1).

Analysis We take the bottle as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances can be expressed as

$$\text{Mass balance: } m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_i = m_2 \quad (\text{since } m_{\text{out}} = m_{\text{initial}} = 0)$$

Energy balance:

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} + m_i h_i = m_2 u_2 \quad (\text{since } W \cong E_{\text{out}} = E_{\text{initial}} = ke \cong pe \cong 0)$$

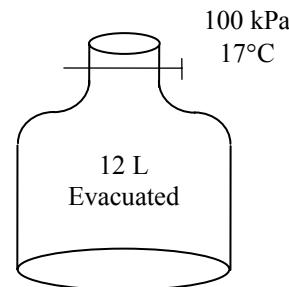

Combining the two balances:

$$Q_{\text{in}} = m_2 (u_2 - h_i)$$

where

$$m_2 = \frac{P_2 V}{RT_2} = \frac{(100 \text{ kPa})(0.012 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(290 \text{ K})} = 0.0144 \text{ kg}$$

$$T_i = T_2 = 290 \text{ K} \xrightarrow{\text{Table A-17}} \begin{aligned} h_i &= 290.16 \text{ kJ/kg} \\ u_2 &= 206.91 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$Q_{\text{in}} = (0.0144 \text{ kg})(206.91 - 290.16) \text{ kJ/kg} = -1.2 \text{ kJ} \rightarrow Q_{\text{out}} = 1.2 \text{ kJ}$$

Note that the negative sign for heat transfer indicates that the assumed direction is wrong. Therefore, we reversed the direction.

The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the bottle and its immediate surroundings so that the boundary temperature of the extended system is the temperature of the surroundings at all times. The entropy balance for it can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$m_i s_i - \frac{Q_{\text{out}}}{T_{b,\text{in}}} + S_{\text{gen}} = \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1^{\circ 0} = m_2 s_2$$

Therefore, the total entropy generated during this process is

$$S_{\text{gen}} = -m_i s_i + m_2 s_2 + \frac{Q_{\text{out}}}{T_{b,\text{out}}} = m_2 (s_2 - s_i)^{\circ 0} + \frac{Q_{\text{out}}}{T_{b,\text{out}}} = \frac{Q_{\text{out}}}{T_{\text{surr}}} = \frac{1.2 \text{ kJ}}{290 \text{ K}} = 0.00415 \text{ kJ/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (290 \text{ K})(0.00415 \text{ kJ/K}) = 1.2 \text{ kJ}$$

8-123 Argon gas in a piston–cylinder device expands isothermally as a result of heat transfer from a furnace. The useful work output, the exergy destroyed, and the reversible work are to be determined.

Assumptions 1 Argon at specified conditions can be treated as an ideal gas since it is well above its critical temperature of 151 K. **2** The kinetic and potential energies are negligible.

Analysis We take the *argon gas* contained within the piston–cylinder device as the system. This is a *closed system* since no mass crosses the system boundary during the process. We note that heat is transferred to the system from a source at 1200 K, but there is no heat exchange with the environment at 300 K. Also, the temperature of the system remains constant during the expansion process, and its volume doubles, that is, $T_2 = T_1$ and $V_2 = 2V_1$.

(a) The only work interaction involved during this isothermal process is the quasi-equilibrium boundary work, which is determined from

$$W = W_b = \int_1^2 P dV = P_1 V_1 \ln \frac{V_2}{V_1} = (350 \text{ kPa})(0.01 \text{ m}^3) \ln \frac{0.02 \text{ m}^3}{0.01 \text{ m}^3} = 2.43 \text{ kPa} \cdot \text{m}^3 = 2.43 \text{ kJ}$$

This is the total boundary work done by the argon gas. Part of this work is done against the atmospheric pressure P_0 to push the air out of the way, and it cannot be used for any useful purpose. It is determined from

$$W_{\text{surr}} = P_0(V_2 - V_1) = (100 \text{ kPa})(0.02 - 0.01) \text{ m}^3 = 1 \text{ kPa} \cdot \text{m}^3 = 1 \text{ kJ}$$

The useful work is the difference between these two:

$$W_u = W - W_{\text{surr}} = 2.43 - 1 = \mathbf{1.43 \text{ kJ}}$$

That is, 1.43 kJ of the work done is available for creating a useful effect such as rotating a shaft. Also, the heat transfer from the furnace to the system is determined from an energy balance on the system to be

$$\begin{aligned} \underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} &= \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ Q_{\text{in}} - Q_{\text{b,out}} &= \Delta U = mc_v \Delta T = 0 \\ Q_{\text{in}} &= Q_{\text{b,out}} = 2.43 \text{ kJ} \end{aligned}$$

(b) The exergy destroyed during a process can be determined from an exergy balance, or directly from $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. We will use the second approach since it is usually easier. But first we determine the entropy generation by

applying an entropy balance on an *extended system* (system + immediate surroundings), which includes the temperature gradient zone between the cylinder and the furnace so that the temperature at the boundary where heat

transfer occurs is $T_R = 1200 \text{ K}$. This way, the entropy generation associated with the heat transfer is included. Also, the entropy change of the argon gas can be determined from Q/T_{sys} since its temperature remains constant.

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} &= \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ \frac{Q}{T_R} + S_{\text{gen}} &= \Delta S_{\text{sys}} = \frac{Q}{T_{\text{sys}}} \end{aligned}$$

Therefore,

$$S_{\text{gen}} = \frac{Q}{T_{\text{sys}}} - \frac{Q}{T_R} = \frac{2.43 \text{ kJ}}{400 \text{ K}} - \frac{2.43 \text{ kJ}}{1200 \text{ K}} = 0.00405 \text{ kJ/K}$$

and

$$X_{\text{dest}} = T_0 S_{\text{gen}} = (300 \text{ K})(0.00405 \text{ kJ/K}) = \mathbf{1.22 \text{ kJ}}$$

(c) The reversible work, which represents the maximum useful work that could be produced $W_{rev,out}$, can be determined from the exergy balance by setting the exergy destruction equal to zero,

$$\begin{aligned} \underbrace{X_{in} - X_{out}}_{\text{Net exergy transfer by heat, work, and mass}} - \underbrace{X_{destroyed}^{T_0 \text{ (reversible)}}}_{\text{Exergy destruction}} &= \underbrace{\Delta X_{\text{system}}}_{\text{Change in exergy}} \\ \left(1 - \frac{T_0}{T_b}\right)Q - W_{rev,out} &= X_2 - X_1 \\ &= (U_2 - U_1) + P_0(\nu_2 - \nu_1) - T_0(S_2 - S_1) \\ &= 0 + W_{surr} - T_0 \frac{Q}{T_{sys}} \end{aligned}$$

since $\Delta KE = \Delta PE = 0$ and $\Delta U = 0$ (the change in internal energy of an ideal gas is zero during an isothermal process), and $\Delta S_{sys} = Q/T_{sys}$ for isothermal processes in the absence of any irreversibilities. Then,

$$\begin{aligned} W_{rev,out} &= T_0 \frac{Q}{T_{sys}} - W_{surr} + \left(1 - \frac{T_0}{T_R}\right)Q \\ &= (300 \text{ K}) \frac{2.43 \text{ kJ}}{400 \text{ K}} - (1 \text{ kJ}) + \left(1 - \frac{300 \text{ K}}{1200 \text{ K}}\right)(2.43 \text{ kJ}) \\ &= \mathbf{2.65 \text{ kJ}} \end{aligned}$$

Therefore, the useful work output would be 2.65 kJ instead of 1.43 kJ if the process were executed in a totally reversible manner.

Alternative Approach The reversible work could also be determined by applying the basics only, without resorting to exergy balance. This is done by replacing the irreversible portions of the process by reversible ones that create the same effect on the system. The useful work output of this idealized process (between the actual end states) is the reversible work. The only irreversibility the actual process involves is the heat transfer between the system and the furnace through a finite temperature difference. This irreversibility can be eliminated by operating a reversible heat engine between the furnace at 1200 K and the surroundings at 300 K. When 2.43 kJ of heat is supplied to this heat engine, it produces a work output of

$$W_{HE} = \eta_{rev} Q_H = \left(1 - \frac{T_L}{T_H}\right)Q_H = \left(1 - \frac{300 \text{ K}}{1200 \text{ K}}\right)(2.43 \text{ kJ}) = 1.82 \text{ kJ}$$

The 2.43 kJ of heat that was transferred to the system from the source is now extracted from the surrounding air at 300 K by a reversible heat pump that requires a work input of

$$W_{HP,in} = \frac{Q_H}{COP_{HP}} = \frac{Q_H}{T_H / (T_H - T_L)} = \frac{2.43 \text{ kJ}}{(400 \text{ K}) / (400 - 300 \text{ K})} = 0.61 \text{ kJ}$$

Then the net work output of this reversible process (i.e., the reversible work) becomes

$$W_{rev} = W_u + W_{HE} - W_{HP,in} = 1.43 + 1.82 - 0.61 = 2.64 \text{ kJ}$$

which is practically identical to the result obtained before. Also, the exergy destroyed is the difference between the reversible work and the useful work, and is determined to be

$$X_{dest} = W_{rev,out} - W_{u,out} = 2.65 - 1.43 = 1.22 \text{ kJ}$$

which is identical to the result obtained before.

8-124 A heat engine operates between two constant-pressure cylinders filled with air at different temperatures. The maximum work that can be produced and the final temperatures of the cylinders are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $0.287 \text{ kPa.m}^3/\text{kg.K}$ (Table A-1). The constant pressure specific heat of air at room temperature is $c_p = 1.005 \text{ kJ/kg.K}$ (Table A-2).

Analysis For maximum power production, the entropy generation must be zero. We take the two cylinders (the heat source and heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}}^{\neq 0} &= \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}} \\ 0 + S_{\text{gen}}^{\neq 0} &= \Delta S_{\text{cylinder,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}}^{\neq 0} \\ \Delta S_{\text{cylinder,source}} + \Delta S_{\text{cylinder,sink}} &= 0 \\ \left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{source}} + 0 + \left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{sink}}^{\neq 0} &= 0 \\ \ln \frac{T_2}{T_{1A}} \frac{T_2}{T_{1B}} = 0 &\longrightarrow T_2^2 = T_{1A} T_{1B} \end{aligned}$$

where T_{1A} and T_{1B} are the initial temperatures of the source and the sink, respectively, and T_2 is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = \sqrt{T_{1A} T_{1B}} = \sqrt{(900 \text{ K})(300 \text{ K})} = 519.6 \text{ K}$$

The energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for the source and sink can be expressed as follows:

Source:

$$-Q_{\text{source,out}} + W_{b,in} = \Delta U \rightarrow Q_{\text{source,out}} = \Delta H = mc_p(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_p(T_{1A} - T_2) = (30 \text{ kg})(1.005 \text{ kJ/kg.K})(900 - 519.6) \text{ K} = 11,469 \text{ kJ}$$

Sink:

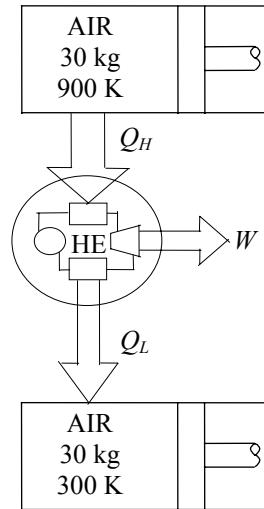

$$Q_{\text{sink,in}} - W_{b,out} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p(T_2 - T_{1B})$$

$$Q_{\text{sink,in}} = mc_p(T_2 - T_{1B}) = (30 \text{ kg})(1.005 \text{ kJ/kg.K})(519.6 - 300) \text{ K} = 6621 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 11,469 - 6621 = 4847 \text{ kJ}$$

Therefore, a maximum of 4847 kJ of work can be produced during this process

8-125 A heat engine operates between a nitrogen tank and an argon cylinder at different temperatures. The maximum work that can be produced and the final temperatures are to be determined.

Assumptions Nitrogen and argon are ideal gases with constant specific heats at room temperature.

Properties The constant volume specific heat of nitrogen at room temperature is $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$. The constant pressure specific heat of argon at room temperature is $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$ (Table A-2).

Analysis For maximum power production, the entropy generation must be zero. We take the tank, the cylinder (the heat source and the heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}^{\neq 0}}_{\text{Entropy generation}} + \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}} &= 0 \\ 0 + S_{\text{gen}}^{\neq 0} &= \Delta S_{\text{tank,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}}^{\neq 0} \\ (\Delta S)_{\text{source}} + (\Delta S)_{\text{sink}} &= 0 \\ \left(mc_v \ln \frac{T_2}{T_1} - mR \ln \frac{V_2^{\neq 0}}{V_1} \right)_{\text{source}} + 0 + \left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2^{\neq 0}}{P_1} \right)_{\text{sink}} &= 0 \end{aligned}$$

Substituting,

$$(20 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K}) \ln \frac{T_2}{1000 \text{ K}} + (10 \text{ kg})(0.5203 \text{ kJ/kg}\cdot\text{K}) \ln \frac{T_2}{300 \text{ K}} = 0$$

Solving for T_2 yields

$$T_2 = 731.8 \text{ K}$$

where T_2 is the common final temperature of the tanks for maximum power production.

The energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for the source and sink can be expressed as follows:

Source:

$$-Q_{\text{source,out}} = \Delta U = mc_v(T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = mc_v(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_v(T_{1A} - T_2) = (20 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K})(1000 - 731.8)\text{K} = 3985 \text{ kJ}$$

Sink:

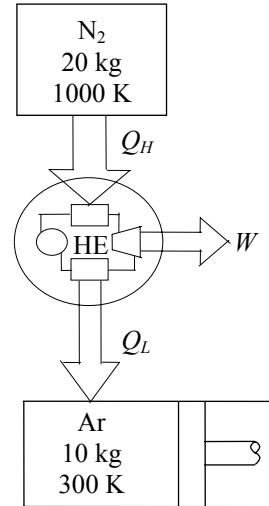

$$Q_{\text{sink,in}} - W_{\text{b,out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p(T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p(T_2 - T_{1A}) = (10 \text{ kg})(0.5203 \text{ kJ/kg}\cdot\text{K})(731.8 - 300)\text{K} = 2247 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 3985 - 2247 = 1739 \text{ kJ}$$

Therefore, a maximum of 1739 kJ of work can be produced during this process

8-126 A rigid tank containing nitrogen is considered. Heat is now transferred to the nitrogen from a reservoir and nitrogen is allowed to escape until the mass of nitrogen becomes one-half of its initial mass. The change in the nitrogen's work potential is to be determined.

Assumptions 1 This is an unsteady process since the conditions within the device are changing during the process. **2** Kinetic and potential energies are negligible. **3** There are no work interactions involved. **4** Nitrogen is an ideal gas with constant specific heats.

Properties The properties of nitrogen at room temperature are $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

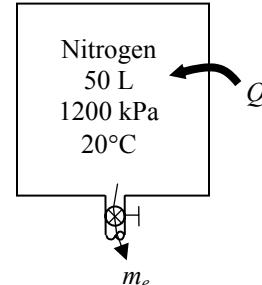

Analysis The initial and final masses in the tank are

$$m_1 = \frac{PV}{RT_1} = \frac{(1200 \text{ kPa})(0.050 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 0.690 \text{ kg}$$

$$m_2 = m_e = \frac{m_1}{2} = \frac{0.690 \text{ kg}}{2} = 0.345 \text{ kg}$$

The final temperature in the tank is

$$T_2 = \frac{PV}{m_2 R} = \frac{(1200 \text{ kPa})(0.050 \text{ m}^3)}{(0.345 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 586 \text{ K}$$

We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

Mass balance:

$$m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_2$$

Energy balance:

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} - m_e h_e = m_2 u_2 - m_1 u_1$$

$$Q_{\text{out}} = m_e h_e + m_2 u_2 - m_1 u_1$$

Using the average of the initial and final temperatures for the exiting nitrogen, $T_e = 0.5(T_1 + T_2) = 0.5((293 + 586) = 439.5 \text{ K}$ this energy balance equation becomes

$$\begin{aligned} Q_{\text{out}} &= m_e h_e + m_2 u_2 - m_1 u_1 \\ &= m_e c_p T_e + m_2 c_v T_2 - m_1 c_v T_1 \\ &= (0.345)(1.039)(439.5) + (0.345)(0.743)(586) - (0.690)(0.743)(293) \\ &= 157.5 \text{ kJ} \end{aligned}$$

The work potential associated with this process is equal to the exergy destroyed during the process. The exergy destruction during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. The entropy generation S_{gen} in this case is determined from an entropy balance on the system:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\frac{Q_{\text{in}}}{T_R} - m_e s_e + S_{\text{gen}} = \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1$$

$$S_{\text{gen}} = m_2 s_2 - m_1 s_1 + m_e s_e - \frac{Q_{\text{in}}}{T_R}$$

Noting that pressures are same, rearranging and substituting gives

$$\begin{aligned}
 S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e - \frac{Q_{\text{in}}}{T_R} \\
 &= m_2 c_p \ln T_2 - m_1 c_p \ln T_1 + m_e c_p \ln T_e - \frac{Q_{\text{in}}}{T_R} \\
 &= (0.345)(1.039) \ln(586) - (0.690)(1.039) \ln(293) + (0.345)(1.039) \ln(439.5) - \frac{157.5}{773} \\
 &= 0.190 \text{ kJ/K}
 \end{aligned}$$

Then,

$$W_{\text{rev}} = X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(0.190 \text{ kJ/K}) = \mathbf{55.7 \text{ kJ}}$$

Alternative More Accurate Solution

This problem may also be solved by considering the variation of gas temperature at the outlet of the tank. The mass and energy balances are

$$\begin{aligned}
 \dot{m}_e &= -\frac{dm}{dt} \\
 \dot{Q} &= \frac{d(mu)}{dt} - h \frac{dm}{dt} = \frac{c_v d(mT)}{dt} - c_p T \frac{dm}{dt}
 \end{aligned}$$

Combining these expressions and replacing T in the last term gives

$$\dot{Q} = c_v \frac{d(mT)}{dt} - \frac{c_p P \nabla}{Rm} \frac{dm}{dt}$$

Integrating this over the time required to release one-half the mass produces

$$Q = c_v (m_2 T_2 - m_1 T_1) - \frac{c_p P \nabla}{R} \ln \frac{m_2}{m_1}$$

The reduced combined first and second law becomes

$$\dot{W}_{\text{rev}} = \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

when the mass balance is substituted and the entropy generation is set to zero (for maximum work production). Expanding the system time derivative gives

$$\begin{aligned}
 \dot{W}_{\text{rev}} &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(mu - T_0 ms)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
 &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(mu)}{dt} + T_0 m \frac{ds}{dt} + T_0 s \frac{dm}{dt} + (h - T_0 s) \frac{dm}{dt} \\
 &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(mu)}{dt} + h \frac{dm}{dt} + m \frac{T_0}{T} \frac{dh}{dt}
 \end{aligned}$$

Substituting \dot{Q} from the first law,

$$\begin{aligned}\dot{W}_{\text{rev}} &= \left[\frac{d(mu)}{dt} - h \frac{dm}{dt} \right] \left[1 - \frac{T_0}{T_R} \right] - \left[\frac{d(mu)}{dt} - h \frac{dm}{dt} \right] + m \frac{T_0}{T} \frac{dh}{dt} \\ &= -\frac{T_0}{T_R} \left[\frac{d(mu)}{dt} - h \frac{dm}{dt} - m \frac{dh}{dt} \right] \\ &= -\frac{T_0}{T_R} \left[c_v \frac{d(mT)}{dt} - c_p T \frac{dm}{dt} - m c_p \frac{dT}{dt} \right]\end{aligned}$$

At any time,

$$T = \frac{P\mathbf{V}}{mR}$$

which further reduces this result to

$$\dot{W}_{\text{rev}} = \frac{T_0}{T_R} c_p \frac{P\mathbf{V}}{mR} \frac{dm}{dt} + T_0 m \left(\frac{c_p}{T} \frac{dT}{dt} - \frac{R}{P} \frac{dP}{dt} \right)$$

When this integrated over the time to complete the process, the result is

$$\begin{aligned}W_{\text{rev}} &= \frac{T_0}{T_R} \frac{c_p P\mathbf{V}}{R} \ln \frac{m_2}{m_1} + T_0 \frac{c_p P\mathbf{V}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ &= \frac{293}{773} \frac{(1.039)(1200)(0.050)}{0.2968} \ln \frac{1}{2} + (293) \frac{(1.039)(1200)(0.050)}{0.2968} \left(\frac{1}{293} - \frac{1}{586} \right) \\ &= \mathbf{49.8 \text{ kJ}}\end{aligned}$$

8-127 A rigid tank containing nitrogen is considered. Nitrogen is allowed to escape until the mass of nitrogen becomes one-half of its initial mass. The change in the nitrogen's work potential is to be determined.

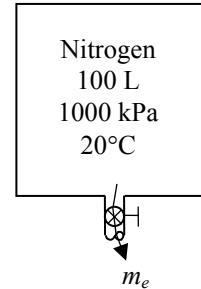

Assumptions 1 This is an unsteady process since the conditions within the device are changing during the process. **2** Kinetic and potential energies are negligible. **3** There are no work interactions involved. **4** Nitrogen is an ideal gas with constant specific heats.

Properties The properties of nitrogen at room temperature are $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$, and $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis The initial and final masses in the tank are

$$m_1 = \frac{PV}{RT_1} = \frac{(1000 \text{ kPa})(0.100 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 1.150 \text{ kg}$$

$$m_2 = m_e = \frac{m_1}{2} = \frac{1.150 \text{ kg}}{2} = 0.575 \text{ kg}$$

We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

Mass balance:

$$m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_2$$

Energy balance:

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$-m_e h_e = m_2 u_2 - m_1 u_1$$

Using the average of the initial and final temperatures for the exiting nitrogen, this energy balance equation becomes

$$\begin{aligned} -m_e h_e &= m_2 u_2 - m_1 u_1 \\ -m_e c_p T_e &= m_2 c_v T_2 - m_1 c_v T_1 \\ -(0.575)(1.039)(0.5)(293 + T_2) &= (0.575)(0.743)T_2 - (1.150)(0.743)(293) \end{aligned}$$

Solving for the final temperature, we get

$$T_2 = 224.3 \text{ K}$$

The final pressure in the tank is

$$P_2 = \frac{m_2 RT_2}{V} = \frac{(0.575 \text{ kg})(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(224.3 \text{ K})}{0.100 \text{ m}^3} = 382.8 \text{ kPa}$$

The average temperature and pressure for the exiting nitrogen is

$$T_e = 0.5(T_1 + T_2) = 0.5(293 + 224.3) = 258.7 \text{ K}$$

$$P_e = 0.5(P_1 + P_2) = 0.5(1000 + 382.8) = 691.4 \text{ kPa}$$

The work potential associated with this process is equal to the exergy destroyed during the process. The exergy destruction during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. The entropy generation S_{gen} in this case is determined from an entropy balance on the system:

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} &= \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ -m_e s_e + S_{\text{gen}} &= \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1 \\ S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e \end{aligned}$$

Rearranging and substituting gives

$$\begin{aligned}
 S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e \\
 &= m_2(c_p \ln T_2 - R \ln P_2) - m_1(c_p \ln T_1 - R \ln P_1) + m_e(c_p \ln T_e - R \ln P_e) \\
 &= (0.575)[1.039 \ln(224.3) - (0.2968) \ln(382.8)] - (1.15)[1.039 \ln(293) - (0.2968) \ln(1000)] \\
 &\quad + (0.575)[1.039 \ln(258.7) - (0.2968) \ln(691.4)] \\
 &= 2.2188 - 4.4292 + 2.2032 = -0.007152 \text{ kJ/K}
 \end{aligned}$$

Then,

$$W_{\text{rev}} = X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(-0.007152 \text{ kJ/K}) = -2.10 \text{ kJ}$$

The entropy generation cannot be negative for a thermodynamically possible process. This result is probably due to using average temperature and pressure values for the exiting gas and using constant specific heats for nitrogen. This sensitivity occurs because the entropy generation is very small in this process.

Alternative More Accurate Solution

This problem may also be solved by considering the variation of gas temperature and pressure at the outlet of the tank. The mass balance in this case is

$$\dot{m}_e = -\frac{dm}{dt}$$

which when combined with the reduced first law gives

$$\frac{d(mu)}{dt} = h \frac{dm}{dt}$$

Using the specific heats and the ideal gas equation of state reduces this to

$$c_v \frac{\nu}{R} \frac{dP}{dt} = c_p T \frac{dm}{dt}$$

which upon rearrangement and an additional use of ideal gas equation of state becomes

$$\frac{1}{P} \frac{dP}{dt} = \frac{c_p}{c_v} \frac{1}{m} \frac{dm}{dt}$$

When this is integrated, the result is

$$P_2 = P_1 \left(\frac{m_2}{m_1} \right)^k = 1000 \left(\frac{1}{2} \right)^{1.4} = 378.9 \text{ kPa}$$

The final temperature is then

$$T_2 = \frac{P_2 \nu}{m_2 R} = \frac{(378.9 \text{ kPa})(0.100 \text{ m}^3)}{(0.575 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 222.0 \text{ K}$$

The process is then one of

$$\frac{m^k}{P} = \text{const} \quad \text{or} \quad \frac{m^{k-1}}{T} = \text{const}$$

The reduced combined first and second law becomes

$$\dot{W}_{\text{rev}} = -\frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

when the mass balance is substituted and the entropy generation is set to zero (for maximum work production). Replacing the enthalpy term with the first law result and canceling the common dU/dt term reduces this to

$$\dot{W}_{\text{rev}} = T_0 \frac{d(ms)}{dt} - T_0 s \frac{dm}{dt}$$

Expanding the first derivative and canceling the common terms further reduces this to

$$\dot{W}_{\text{rev}} = T_0 m \frac{ds}{dt}$$

Letting $a = P_1 / m_1^k$ and $b = T_1 / m_1^{k-1}$, the pressure and temperature of the nitrogen in the system are related to the mass by

$$P = am^k \quad \text{and} \quad T = bm^{k-1}$$

according to the first law. Then,

$$dP = akm^{k-1}dm \quad \text{and} \quad dT = b(k-1)m^{k-2}dm$$

The entropy change relation then becomes

$$ds = c_p \frac{dT}{T} - R \frac{dP}{P} = [(k-1)c_p - Rk] \frac{dm}{m}$$

Now, multiplying the combined first and second laws by dt and integrating the result gives

$$\begin{aligned} W_{\text{rev}} &= T_0 \int_1^2 mds = T_0 \int_1^2 mds [(k-1)c_p - Rk] dm \\ &= T_0 [(k-1)c_p - Rk] [m_2 - m_1] \\ &= (293) [(1.4-1)(1.039) - (0.2968)(1.4)] (0.575 - 1.15) \\ &= \mathbf{-0.0135 \text{ kJ}} \end{aligned}$$

Once again the entropy generation is negative, which cannot be the case for a thermodynamically possible process. This is probably due to using constant specific heats for nitrogen. This sensitivity occurs because the entropy generation is very small in this process.

8-128 Steam is condensed by cooling water in the condenser of a power plant. The rate of condensation of steam and the rate of exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** Fluid properties are constant.

Properties The enthalpy and entropy of vaporization of water at 45°C are $h_{fg} = 2394.0 \text{ kJ/kg}$ and $s_{fg} = 7.5247 \text{ kJ/kg.K}$ (Table A-4). The specific heat of water at room temperature is $c_p = 4.18 \text{ kJ/kg}\cdot\text{°C}$ (Table A-3).

Analysis (a) We take the cold water tubes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{in} - \dot{E}_{out}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}^{\pi 0 (\text{steady})}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta h_e \approx \Delta h_p \approx 0)$$

$$\dot{Q}_{in} = \dot{m}c_p(T_2 - T_1)$$

Then the heat transfer rate to the cooling water in the condenser becomes

$$\begin{aligned} \dot{Q} &= [\dot{m}c_p(T_{out} - T_{in})]_{\text{cooling water}} \\ &= (330 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot\text{°C})(20\text{°C} - 12\text{°C}) \\ &= 11,035 \text{ kJ/s} \end{aligned}$$

The rate of condensation of steam is determined to be

$$\dot{Q} = (\dot{m}h_{fg})_{\text{steam}} \longrightarrow \dot{m}_{\text{steam}} = \frac{\dot{Q}}{h_{fg}} = \frac{11,035 \text{ kJ/s}}{2394.0 \text{ kJ/kg}} = 4.61 \text{ kg/s}$$

(b) The rate of entropy generation within the condenser during this process can be determined by applying the rate form of the entropy balance on the entire condenser. Noting that the condenser is well-insulated and thus heat transfer is negligible, the entropy balance for this steady-flow system can be expressed as

$$\underbrace{\dot{S}_{in} - \dot{S}_{out}}_{\substack{\text{Rate of net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{\dot{S}_{gen}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}^{\pi 0 (\text{steady})}}_{\text{Rate of change of entropy}}$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{gen} = 0 \quad (\text{since } Q = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{steam}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{steam}} s_4 + \dot{S}_{gen} = 0$$

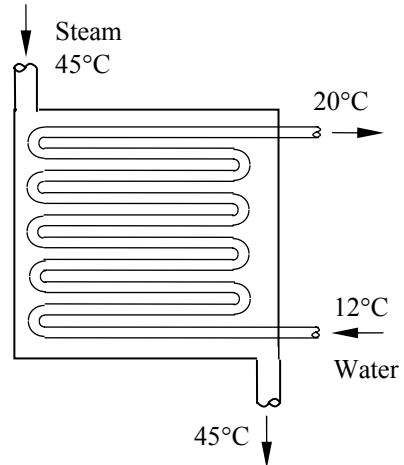

$$\dot{S}_{gen} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{steam}}(s_4 - s_3)$$

Noting that water is an incompressible substance and steam changes from saturated vapor to saturated liquid, the rate of entropy generation is determined to be

$$\begin{aligned} \dot{S}_{gen} &= \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{steam}} (s_f - s_g) = \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} - \dot{m}_{\text{steam}} s_{fg} \\ &= (330 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot\text{K}) \ln \frac{20 + 273}{12 + 273} - (4.61 \text{ kg/s})(7.5247 \text{ kJ/kg}\cdot\text{K}) = 3.501 \text{ kW/K} \end{aligned}$$

Then the exergy destroyed can be determined directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$ to be

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{gen} = (285 \text{ K})(3.501 \text{ kW/K}) = 998 \text{ kW}$$

8-129 A system consisting of a compressor, a storage tank, and a turbine as shown in the figure is considered. The change in the exergy of the air in the tank and the work required to compress the air as the tank was being filled are to be determined.

Assumptions 1 Changes in the kinetic and potential energies are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$ (Table A-2a).

Analysis The initial mass of air in the tank is

$$m_{\text{initial}} = \frac{P_{\text{initial}} V}{RT_{\text{initial}}} = \frac{(100 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 0.5946 \times 10^6 \text{ kg}$$

and the final mass in the tank is

$$m_{\text{final}} = \frac{P_{\text{final}} V}{RT_{\text{final}}} = \frac{(600 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 3.568 \times 10^6 \text{ kg}$$

Since the compressor operates as an isentropic device,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k}$$

The conservation of mass applied to the tank gives

$$\frac{dm}{dt} = \dot{m}_{\text{in}}$$

while the first law gives

$$\dot{Q} = \frac{d(mu)}{dt} - h \frac{dm}{dt}$$

Employing the ideal gas equation of state and using constant specific heats, expands this result to

$$\dot{Q} = \frac{\nu c_v}{R} \frac{dP}{dt} - c_p T_2 \frac{V}{RT} \frac{dP}{dt}$$

Using the temperature relation across the compressor and multiplying by dt puts this result in the form

$$\dot{Q} dt = \frac{\nu c_v}{R} dP - c_p T_1 \left(\frac{P}{P_1} \right)^{(k-1)/k} \frac{V}{RT} dP$$

When this integrated, it yields (i and f stand for initial and final states)

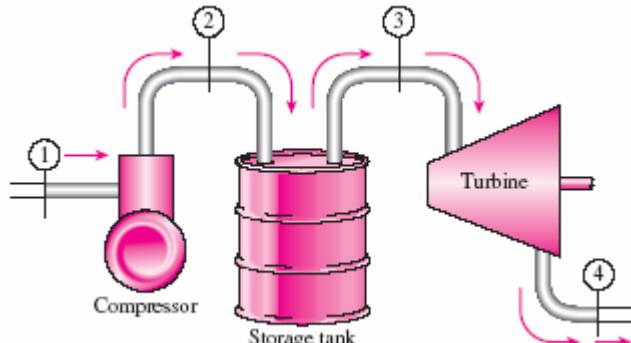

$$\begin{aligned} Q &= \frac{\nu c_v}{R} (P_f - P_i) - \frac{k}{2k-1} \frac{c_p V}{R} \left[P_f \left(\frac{P_f}{P_i} \right)^{(k-1)/k} - P_i \right] \\ &= \frac{(5 \times 10^5)(0.718)}{0.287} (600 - 100) - \frac{1.4}{2(1.4)-1} \frac{(1.005)(5 \times 10^5)}{0.287} \left[600 \left(\frac{600}{100} \right)^{0.4/1.4} - 100 \right] \\ &= -6.017 \times 10^8 \text{ kJ} \end{aligned}$$

The negative result shows that heat is transferred from the tank. Applying the first law to the tank and compressor gives

$$(\dot{Q} - \dot{W}_{\text{out}}) dt = d(mu) - h_1 dm$$

which integrates to

$$Q - W_{\text{out}} = (m_f u_f - m_i u_i) - h_1 (m_f - m_i)$$

Upon rearrangement,

$$\begin{aligned} W_{\text{out}} &= Q + (c_p - c_v)T(m_f - m_i) \\ &= -6.017 \times 10^8 + (1.005 - 0.718)(293)[(3.568 - 0.5946) \times 10^6] \\ &= \mathbf{-3.516 \times 10^8 \text{ kJ}} \end{aligned}$$

The negative sign shows that work is done on the compressor. When the combined first and second laws is reduced to fit the compressor and tank system and the mass balance incorporated, the result is

$$\dot{W}_{\text{rev}} = \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

which when integrated over the process becomes

$$\begin{aligned} W_{\text{rev}} &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) + m_i [(u_i - h_i) - T_0(s_i - s_1)] - m_f [(u_f - h_i) - T_0(s_f - s_1)] \\ &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) + m_i [T_i(c_v - c_p)] - m_f \left[T_f(c_v - c_p) - T_0 R \ln \left(\frac{P_f}{P_i} \right) \right] \\ &= -6.017 \times 10^8 \left(1 - \frac{293}{293} \right) + 0.5946 \times 10^6 [(0.718 - 1.005)293] \\ &\quad - 3.568 \times 10^6 \left[(0.718 - 1.005)293 + 293(0.287) \ln \frac{600}{100} \right] \\ &= \mathbf{7.875 \times 10^8 \text{ kJ}} \end{aligned}$$

This is the exergy change of the air stored in the tank.

8-130 The air stored in the tank of the system shown in the figure is released through the isentropic turbine. The work produced and the change in the exergy of the air in the tank are to be determined.

Assumptions 1 Changes in the kinetic and potential energies are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$ (Table A-2a).

Analysis The initial mass of air in the tank is

$$m_{\text{initial}} = \frac{P_{\text{initial}} V}{RT_{\text{initial}}} = \frac{(600 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 3.568 \times 10^6 \text{ kg}$$

and the final mass in the tank is

$$m_{\text{final}} = \frac{P_{\text{final}} V}{RT_{\text{final}}} = \frac{(100 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 0.5946 \times 10^6 \text{ kg}$$

The conservation of mass is

$$\frac{dm}{dt} = \dot{m}_{\text{in}}$$

while the first law gives

$$\dot{Q} = \frac{d(mu)}{dt} - h \frac{dm}{dt}$$

Employing the ideal gas equation of state and using constant specific heats, expands this result to

$$\begin{aligned} \dot{Q} &= \frac{V c_v}{R} \frac{dP}{dt} - c_p T \frac{V}{RT} \frac{dP}{dt} \\ &= \frac{c_v - c_p}{R} V \frac{dP}{dt} \\ &= -V \frac{dP}{dt} \end{aligned}$$

When this is integrated over the process, the result is (i and f stand for initial and final states)

$$Q = -V(P_f - P_i) = -5 \times 10^5 (100 - 600) = 2.5 \times 10^8 \text{ kJ}$$

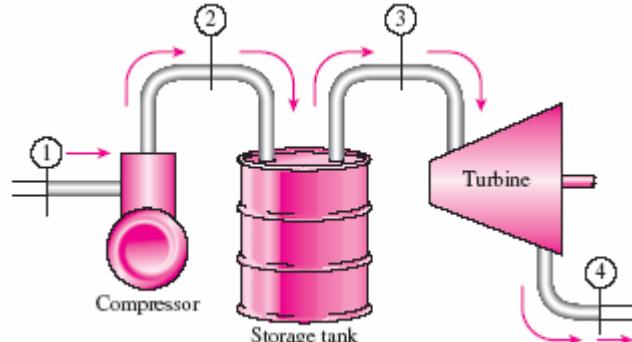

Applying the first law to the tank and compressor gives

$$(\dot{Q} - \dot{W}_{\text{out}}) dt = d(mu) - h dm$$

which integrates to

$$\begin{aligned} Q - W_{\text{out}} &= (m_f u_f - m_i u_i) + h(m_i - m_f) \\ -W_{\text{out}} &= -Q + m_f u_f - m_i u_i + h(m_i - m_f) \\ W_{\text{out}} &= Q - m_f u_f + m_i u_i - h(m_i - m_f) \\ &= Q - m_f c_v T + m_i c_p T - c_p T(m_i - m_f) \\ &= 2.5 \times 10^8 - (0.5946 \times 10^6)(0.718)(293) + (3.568 \times 10^6)(1.005)(293) \\ &\quad - (1.005)(293)(3.568 \times 10^6 - 0.5946 \times 10^6) \\ &= \mathbf{3.00 \times 10^8 \text{ kJ}} \end{aligned}$$

This is the work output from the turbine. When the combined first and second laws is reduced to fit the turbine and tank system and the mass balance incorporated, the result is

$$\begin{aligned}
\dot{W}_{\text{rev}} &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - (u - T_0 s) \frac{dm}{dt} - m \frac{d(u - T_0 s)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T \frac{dm}{dt} + m T_0 \frac{ds}{dt} \\
&= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T \frac{dm}{dt} + \nu \frac{T_0}{T} (P_f - P_i)
\end{aligned}$$

where the last step uses entropy change equation. When this is integrated over the process it becomes

$$\begin{aligned}
W_{\text{rev}} &= Q \left(1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T (m_f - m_i) + \nu \frac{T_0}{T} (P_f - P_i) \\
&= 3.00 \times 10^8 \left(1 - \frac{293}{293} \right) + (1.005 - 0.718)(293)(0.5946 - 3.568) \times 10^6 + 5 \times 10^5 \frac{293}{293} (100 - 600) \\
&= 0 - 2.500 \times 10^8 - 2.5 \times 10^8 \\
&= \mathbf{-5.00 \times 10^8 \text{ kJ}}
\end{aligned}$$

This is the exergy change of the air in the storage tank.

8-131 A heat engine operates between a tank and a cylinder filled with air at different temperatures. The maximum work that can be produced and the final temperatures are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The specific heats of air are $c_v = 0.718 \text{ kJ/kg.K}$ and $c_p = 1.005 \text{ kJ/kg.K}$ (Table A-2).

Analysis For maximum power production, the entropy generation must be zero. We take the tank, the cylinder (the heat source and the heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}^{\gg 0}}_{\text{Entropy generation}} = \Delta S_{\text{system}}$$

$$0 + S_{\text{gen}}^{\gg 0} = \Delta S_{\text{tank,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}}^{\gg 0}$$

$$(\Delta S)_{\text{source}} + (\Delta S)_{\text{sink}} = 0$$

$$\left(m c_v \ln \frac{T_2}{T_1} - m R \ln \frac{V_2}{V_1} \right)_{\text{source}}^{\gg 0} + 0 + \left(m c_p \ln \frac{T_2}{T_1} - m R \ln \frac{P_2}{P_1} \right)_{\text{sink}}^{\gg 0} = 0$$

$$\ln \frac{T_2}{T_{1A}} + \frac{c_p}{c_v} \ln \frac{T_2}{T_{1B}} = 0 \longrightarrow \frac{T_2}{T_{1A}} \left(\frac{T_2}{T_{1B}} \right)^k = 1 \longrightarrow T_2 = (T_{1A} T_{1B})^{1/(k+1)}$$

where T_{1A} and T_{1B} are the initial temperatures of the source and the sink, respectively, and T_2 is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = ((600 \text{ K})(280 \text{ K})^{1/4})^{1/2.4} = 384.7 \text{ K}$$

Source:

$$-Q_{\text{source,out}} = \Delta U = mc_v(T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = mc_v(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_v(T_{1A} - T_2) = (40 \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(600 - 384.7) \text{ K} = 6184 \text{ kJ}$$

Sink:

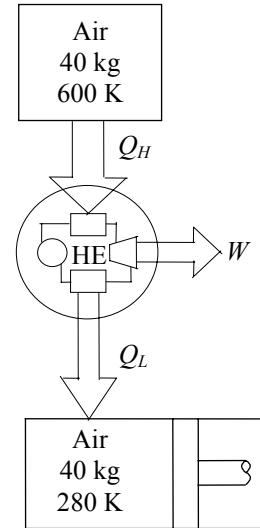

$$Q_{\text{sink,in}} - W_{\text{b,out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p(T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p(T_2 - T_{1A}) = (40 \text{ kg})(1.005 \text{ kJ/kg} \cdot \text{K})(384.7 - 280) \text{ K} = 4208 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 6184 - 4208 = 1977 \text{ kJ}$$

Therefore, a maximum of 1977 kJ of work can be produced during this process.

8-132E Large brass plates are heated in an oven at a rate of 300/min. The rate of heat transfer to the plates in the oven and the rate of exergy destruction associated with this heat transfer process are to be determined.

Assumptions 1 The thermal properties of the plates are constant.
2 The changes in kinetic and potential energies are negligible. **3** The environment temperature is 75°F.

Properties The density and specific heat of the brass are given to be $\rho = 532.5 \text{ lbm/ft}^3$ and $c_p = 0.091 \text{ Btu/lbm.}^\circ\text{F}$.

Analysis We take the plate to be the system. The energy balance for this closed system can be expressed as

$$\underbrace{E_{in} - E_{out}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{system}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{in} = \Delta U_{plate} = m(u_2 - u_1) = mc(T_2 - T_1)$$

The mass of each plate and the amount of heat transfer to each plate is

$$m = \rho V = \rho LA = (532.5 \text{ lbm/ft}^3)[(1.2 / 12 \text{ ft})(2 \text{ ft})(2 \text{ ft})] = 213 \text{ lbm}$$

$$Q_{in} = mc(T_2 - T_1) = (213 \text{ lbm/plate})(0.091 \text{ Btu/lbm.}^\circ\text{F})(1000 - 75)^\circ\text{F} = 17,930 \text{ Btu/plate}$$

Then the total rate of heat transfer to the plates becomes

$$\dot{Q}_{total} = \dot{n}_{plate} Q_{in, \text{per plate}} = (300 \text{ plates/min}) \times (17,930 \text{ Btu/plate}) = \mathbf{5,379,000 \text{ Btu/min} = 89,650 \text{ Btu/s}}$$

We again take a single plate as the system. The entropy generated during this process can be determined by applying an entropy balance on an *extended system* that includes the plate and its immediate surroundings so that the boundary temperature of the extended system is at 1300°F at all times:

$$\underbrace{S_{in} - S_{out}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{gen}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{system}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\frac{Q_{in}}{T_b} + S_{gen} = \Delta S_{system} \rightarrow S_{gen} = -\frac{Q_{in}}{T_b} + \Delta S_{system}$$

where

$$\Delta S_{system} = m(s_2 - s_1) = mc_{avg} \ln \frac{T_2}{T_1} = (213 \text{ lbm})(0.091 \text{ Btu/lbm.R}) \ln \frac{(1000 + 460) \text{ R}}{(75 + 460) \text{ R}} = 19.46 \text{ Btu/R} \text{ Substituting,}$$

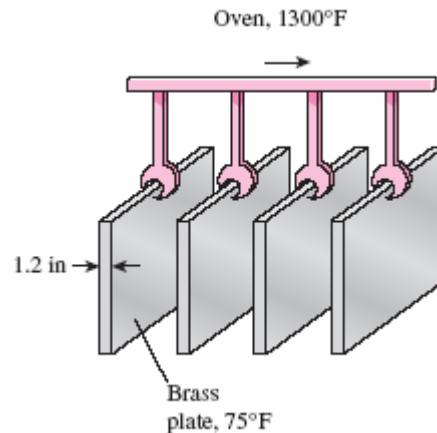

$$S_{gen} = -\frac{Q_{in}}{T_b} + \Delta S_{system} = -\frac{17,930 \text{ Btu}}{1300 + 460 \text{ R}} + 19.46 \text{ Btu/R} = 9.272 \text{ Btu/R (per plate)}$$

Then the rate of entropy generation becomes

$$\dot{S}_{gen} = S_{gen} \dot{n}_{plate} = (9.272 \text{ Btu/R} \cdot \text{plate})(300 \text{ plates/min}) = 2781 \text{ Btu/min.R} = 46.35 \text{ Btu/s.R}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{destroyed} = T_0 S_{gen}$,

$$\dot{X}_{destroyed} = T_0 \dot{S}_{gen} = (535 \text{ R})(46.35 \text{ Btu/s.R}) = \mathbf{24,797 \text{ Btu/s}}$$

8-133 Long cylindrical steel rods are heat-treated in an oven. The rate of heat transfer to the rods in the oven and the rate of exergy destruction associated with this heat transfer process are to be determined.

Assumptions 1 The thermal properties of the rods are constant. **2** The changes in kinetic and potential energies are negligible. **3** The environment temperature is 30°C.

Properties The density and specific heat of the steel rods are given to be $\rho = 7833 \text{ kg/m}^3$ and $c_p = 0.465 \text{ kJ/kg}\cdot\text{°C}$.

Analysis Noting that the rods enter the oven at a velocity of 3 m/min and exit at the same velocity, we can say that a 3-m long section of the rod is heated in the oven in 1 min. Then the mass of the rod heated in 1 minute is

$$m = \rho V = \rho L A = \rho L (\pi D^2 / 4) = (7833 \text{ kg/m}^3)(3 \text{ m})[\pi(0.1 \text{ m})^2 / 4] = 184.6 \text{ kg}$$

We take the 3-m section of the rod in the oven as the system. The energy balance for this closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ Q_{\text{in}} = \Delta U_{\text{rod}} = m(u_2 - u_1) = mc(T_2 - T_1)$$

Substituting,

$$Q_{\text{in}} = mc(T_2 - T_1) = (184.6 \text{ kg})(0.465 \text{ kJ/kg}\cdot\text{°C})(700 - 30)^\circ\text{C} = 57,512 \text{ kJ}$$

Noting that this much heat is transferred in 1 min, the rate of heat transfer to the rod becomes

$$\dot{Q}_{\text{in}} = Q_{\text{in}} / \Delta t = (57,512 \text{ kJ})/(1 \text{ min}) = 57,512 \text{ kJ/min} = \mathbf{958.5 \text{ kW}}$$

We again take the 3-m long section of the rod as the system. The entropy generated during this process can be determined by applying an entropy balance on an *extended system* that includes the rod and its immediate surroundings so that the boundary temperature of the extended system is at 900°C at all times:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ \frac{Q_{\text{in}}}{T_b} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}}$$

where

$$\Delta S_{\text{system}} = m(s_2 - s_1) = mc_{\text{avg}} \ln \frac{T_2}{T_1} = (184.6 \text{ kg})(0.465 \text{ kJ/kg}\cdot\text{K}) \ln \frac{700 + 273}{30 + 273} = 100.1 \text{ kJ/K}$$

Substituting,

$$S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}} = -\frac{57,512 \text{ kJ}}{(900 + 273) \text{ R}} + 100.1 \text{ kJ/K} = 51.1 \text{ kJ/K}$$

Noting that this much entropy is generated in 1 min, the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = \frac{S_{\text{gen}}}{\Delta t} = \frac{51.1 \text{ kJ/K}}{1 \text{ min}} = 51.1 \text{ kJ/min}\cdot\text{K} = 0.852 \text{ kW/K}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(0.852 \text{ kW/K}) = \mathbf{254 \text{ kW}}$$

8-134 Water is heated in a heat exchanger by geothermal water. The rate of heat transfer to the water and the rate of exergy destruction within the heat exchanger are to be determined.

Assumptions 1 Steady operating conditions exist. **2** The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. **3** Changes in the kinetic and potential energies of fluid streams are negligible. **4** Fluid properties are constant. **5** The environment temperature is 25°C.

Properties The specific heats of water and geothermal fluid are given to be 4.18 and 4.31 kJ/kg·°C, respectively.

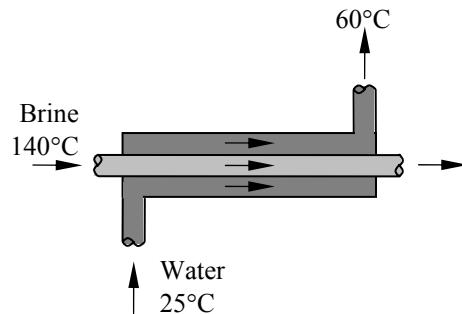

Analysis (a) We take the cold water tubes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{in} - \dot{E}_{out}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}^{\pi 0 \text{ (steady)}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta h_e \approx \Delta h_p \approx 0)$$

$$\dot{Q}_{in} = \dot{m}c_p(T_2 - T_1)$$

Then the rate of heat transfer to the cold water in the heat exchanger becomes

$$\dot{Q}_{in, \text{water}} = [\dot{m}c_p(T_{out} - T_{in})]_{\text{water}} = (0.4 \text{ kg/s})(4.18 \text{ kJ/kg·°C})(60^\circ\text{C} - 25^\circ\text{C}) = \mathbf{58.52 \text{ kW}}$$

Noting that heat transfer to the cold water is equal to the heat loss from the geothermal water, the outlet temperature of the geothermal water is determined from

$$\dot{Q}_{out} = [\dot{m}c_p(T_{in} - T_{out})]_{\text{geo}} \longrightarrow T_{out} = T_{in} - \frac{\dot{Q}_{out}}{\dot{m}c_p} = 140^\circ\text{C} - \frac{58.52 \text{ kW}}{(0.3 \text{ kg/s})(4.31 \text{ kJ/kg·°C})} = 94.7^\circ\text{C}$$

(b) The rate of entropy generation within the heat exchanger is determined by applying the rate form of the entropy balance on the entire heat exchanger:

$$\underbrace{\dot{S}_{in} - \dot{S}_{out}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{gen}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}^{\phi 0 \text{ (steady)}}}_{\text{Rate of change of entropy}}$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{gen} = 0 \quad (\text{since } Q = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{geo}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{geo}} s_4 + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{geo}}(s_4 - s_3)$$

Noting that both fresh and geothermal water are incompressible substances, the rate of entropy generation is determined to be

$$\begin{aligned} \dot{S}_{gen} &= \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{geo}} c_p \ln \frac{T_4}{T_3} \\ &= (0.4 \text{ kg/s})(4.18 \text{ kJ/kg·K}) \ln \frac{60 + 273}{25 + 273} + (0.3 \text{ kg/s})(4.31 \text{ kJ/kg·K}) \ln \frac{94.7 + 273}{140 + 273} = 0.0356 \text{ kW/K} \end{aligned} \quad \text{The exergy}$$

destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{gen} = (298 \text{ K})(0.0356 \text{ kW/K}) = \mathbf{10.61 \text{ kW}}$$

8-135 A regenerator is considered to save heat during the cooling of milk in a dairy plant. The amounts of fuel and money such a generator will save per year and the rate of exergy destruction within the regenerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The properties of the milk are constant. 5 The environment temperature is 18°C.

Properties The average density and specific heat of milk can be taken to be $\rho_{\text{milk}} \approx \rho_{\text{water}} = 1 \text{ kg/L}$ and $c_{p,\text{milk}} = 3.79 \text{ kJ/kg} \cdot ^\circ\text{C}$ (Table A-3).

Analysis The mass flow rate of the milk is

$$\dot{m}_{\text{milk}} = \rho \dot{V}_{\text{milk}} = (1 \text{ kg/L})(12 \text{ L/s}) = 12 \text{ kg/s} = 43,200 \text{ kg/h}$$

Taking the pasteurizing section as the system, the energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}^{\text{0 (steady)}}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} = 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta e \approx \Delta p e \approx 0)$$

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{milk}} c_p (T_2 - T_1)$$

Therefore, to heat the milk from 4 to 72°C as being done currently, heat must be transferred to the milk at a rate of

$$\dot{Q}_{\text{current}} = [\dot{m}c_p(T_{\text{pasteurization}} - T_{\text{refrigeration}})]_{\text{milk}} = (12 \text{ kg/s})(3.79 \text{ kJ/kg} \cdot ^\circ\text{C})(72 - 4)^\circ\text{C} = 3093 \text{ kJ/s}$$

The proposed regenerator has an effectiveness of $\varepsilon = 0.82$, and thus it will save 82 percent of this energy. Therefore,

$$\dot{Q}_{\text{saved}} = \varepsilon \dot{Q}_{\text{current}} = (0.82)(3093 \text{ kJ/s}) = 2536 \text{ kJ/s}$$

Noting that the boiler has an efficiency of $\eta_{\text{boiler}} = 0.82$, the energy savings above correspond to fuel savings of

$$\text{Fuel Saved} = \frac{\dot{Q}_{\text{saved}}}{\eta_{\text{boiler}}} = \frac{(2536 \text{ kJ/s})}{(0.82)} \frac{(1 \text{ therm})}{(105,500 \text{ kJ})} = 0.02931 \text{ therm/s}$$

Noting that 1 year = 365×24=8760 h and unit cost of natural gas is \$1.04/therm, the annual fuel and money savings will be
 $\text{Fuel Saved} = (0.02931 \text{ therm/s})(8760 \times 3600 \text{ s}) = 924,450 \text{ therms/yr}$

$$\text{Money saved} = (\text{Fuel saved})(\text{Unit cost of fuel}) = (924,450 \text{ therm/yr})(\$1.04/\text{therm}) = \$961,430/\text{yr}$$

The rate of entropy generation during this process is determined by applying the rate form of the entropy balance on an *extended system* that includes the regenerator and the immediate surroundings so that the boundary temperature is the surroundings temperature, which we take to be the cold water temperature of 18°C.:

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\substack{\text{Rate of net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}^{\text{0 (steady)}}}_{\text{Rate of change of entropy}} \rightarrow \dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

Disregarding entropy transfer associated with fuel flow, the only significant difference between the two cases is the reduction in the entropy transfer to water due to the reduction in heat transfer to water, and is determined to be

$$\dot{S}_{\text{gen, reduction}} = \dot{S}_{\text{out, reduction}} = \frac{\dot{Q}_{\text{out, reduction}}}{T_{\text{surr}}} = \frac{\dot{Q}_{\text{saved}}}{T_{\text{surr}}} = \frac{2536 \text{ kJ/s}}{18 + 273} = 8.715 \text{ kW/K}$$

$$S_{\text{gen, reduction}} = \dot{S}_{\text{gen, reduction}} \Delta t = (8.715 \text{ kJ/s.K})(8760 \times 3600 \text{ s/year}) = 2.75 \times 10^8 \text{ kJ/K (per year)}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed, reduction}} = T_0 S_{\text{gen, reduction}} = (291 \text{ K})(2.75 \times 10^8 \text{ kJ/K}) = 8.00 \times 10^{10} \text{ kJ (per year)}$$

8-136 Exhaust gases are expanded in a turbine, which is not well-insulated. The actual and reversible power outputs, the exergy destroyed, and the second-law efficiency are to be determined.

PROPRIETARY MATERIAL. © 2011 The McGraw-Hill Companies, Inc. Limited distribution permitted only to teachers and educators for course preparation. If you are a student using this Manual, you are using it without permission.

Assumptions 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Air is an ideal gas with constant specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg.K}$ and the specific heat of air at the average temperature of $(627+527)/2 = 577^\circ\text{C} = 850 \text{ K}$ is $c_p = 1.11 \text{ kJ/kg.\text{C}}$ (Table A-2).

Analysis (a) The enthalpy and entropy changes of air across the turbine are

$$\Delta h = c_p(T_2 - T_1) = (1.11 \text{ kJ/kg.\text{C}})(527 - 627)^\circ\text{C} = -111 \text{ kJ/kg}$$

$$\begin{aligned}\Delta s &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.11 \text{ kJ/kg.K}) \ln \frac{(527 + 273) \text{ K}}{(627 + 273) \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{500 \text{ kPa}}{1200 \text{ kPa}} \\ &= 0.1205 \text{ kJ/kg.K}\end{aligned}$$

The actual and reversible power outputs from the turbine are

$$-\dot{W}_{\text{a,out}} = \dot{m} \Delta h + \dot{Q}_{\text{out}} = (2.5 \text{ kg/s})(-111 \text{ kJ/kg}) + 20 \text{ kW} = \mathbf{-257.5 \text{ kW}}$$

$$-\dot{W}_{\text{rev,out}} = \dot{m}(\Delta h - T_0 \Delta s) = (2.5 \text{ kg/s})(111 \text{ kJ/kg}) - (25 + 273 \text{ K})(0.1205 \text{ kJ/kg.K}) = \mathbf{-367.3 \text{ kW}}$$

or

$$\dot{W}_{\text{a,out}} = \mathbf{257.5 \text{ kW}}$$

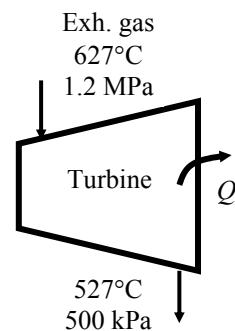

$$\dot{W}_{\text{rev,out}} = \mathbf{367.3 \text{ kW}}$$

(b) The exergy destroyed in the turbine is

$$\dot{X}_{\text{dest}} = \dot{W}_{\text{rev}} - \dot{W}_{\text{a}} = 367.3 - 257.5 = \mathbf{109.8 \text{ kW}}$$

(c) The second-law efficiency is

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{a}}}{\dot{W}_{\text{rev}}} = \frac{257.5 \text{ kW}}{367.3 \text{ kW}} = 0.701 = \mathbf{70.1\%}$$

8-137 Refrigerant-134a is compressed in an adiabatic compressor, whose second-law efficiency is given. The actual work input, the isentropic efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) The properties of the refrigerant at the inlet of the compressor are (Tables A-11 through A-13)

$$T_{\text{sat}@160 \text{ kPa}} = -15.60^\circ\text{C}$$

$$\begin{aligned} P_1 &= 160 \text{ kPa} & h_1 &= 243.60 \text{ kJ/kg} \\ T_1 &= (-15.60 + 3)^\circ\text{C} & s_1 &= 0.95153 \text{ kJ/kg.K} \end{aligned}$$

The enthalpy at the exit for if the process was isentropic is

$$\begin{aligned} P_2 &= 1 \text{ MPa} \\ s_2 &= s_1 = 0.95153 \text{ kJ/kg.K} \end{aligned} \quad \left. \begin{aligned} h_{2s} &= 282.41 \text{ kJ/kg} \end{aligned} \right\}$$

The expressions for actual and reversible works are

$$w_a = h_2 - h_1 = (h_2 - 243.60) \text{ kJ/kg}$$

$$w_{\text{rev}} = h_2 - h_1 - T_0(s_2 - s_1) = (h_2 - 243.60) \text{ kJ/kg} - (25 + 273 \text{ K})(s_2 - 0.95153) \text{ kJ/kg.K}$$

Substituting these into the expression for the second-law efficiency

$$\eta_{II} = \frac{w_{\text{rev}}}{w_a} \longrightarrow 0.80 = \frac{h_2 - 243.60 - (298)(s_2 - 0.95153)}{h_2 - 243.60}$$

The exit pressure is given (1 MPa). We need one more property to fix the exit state. By a trial-error approach or using EES, we obtain the exit temperature to be 60°C. The corresponding enthalpy and entropy values satisfying this equation are

$$h_2 = 293.36 \text{ kJ/kg}$$

$$s_2 = 0.98492 \text{ kJ/kg.K}$$

Then,

$$w_a = h_2 - h_1 = 293.36 - 243.60 = \mathbf{49.76 \text{ kJ/kg}}$$

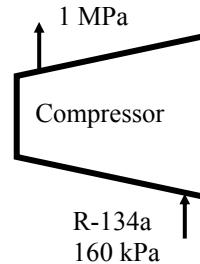

$$w_{\text{rev}} = h_2 - h_1 - T_0(s_2 - s_1) = (293.36 - 243.60) \text{ kJ/kg} - (25 + 273 \text{ K})(0.98492 - 0.9515) \text{ kJ/kg.K} = 39.81 \text{ kJ/kg}$$

(b) The isentropic efficiency is determined from its definition

$$\eta_s = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{(282.41 - 243.60) \text{ kJ/kg}}{(293.36 - 243.60) \text{ kJ/kg}} = \mathbf{0.780}$$

(b) The exergy destroyed in the compressor is

$$x_{\text{dest}} = w_a - w_{\text{rev}} = 49.76 - 39.81 = \mathbf{9.95 \text{ kJ/kg}}$$

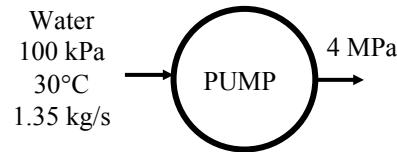

8-138 The isentropic efficiency of a water pump is specified. The actual power output, the rate of frictional heating, the exergy destruction, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) Using saturated liquid properties at the given temperature for the inlet state (Table A-4)

$$\left. \begin{array}{l} T_1 = 30^\circ\text{C} \\ x_1 = 0 \end{array} \right\} \begin{array}{l} h_1 = 125.82 \text{ kJ/kg} \\ s_1 = 0.4367 \text{ kJ/kg.K} \\ v_1 = 0.001004 \text{ m}^3/\text{kg} \end{array}$$

The power input if the process was isentropic is

$$\dot{W}_s = \dot{m}v_1(P_2 - P_1) = (1.35 \text{ kg/s})(0.001004 \text{ m}^3/\text{kg})(4000 - 100) \text{ kPa} = 5.288 \text{ kW}$$

Given the isentropic efficiency, the actual power may be determined to be

$$\dot{W}_a = \frac{\dot{W}_s}{\eta_s} = \frac{5.288 \text{ kW}}{0.70} = \mathbf{7.554 \text{ kW}}$$

(b) The difference between the actual and isentropic works is the frictional heating in the pump

$$\dot{Q}_{\text{frictional}} = \dot{W}_a - \dot{W}_s = 7.554 - 5.288 = \mathbf{2.266 \text{ kW}}$$

(c) The enthalpy at the exit of the pump for the actual process can be determined from

$$\dot{W}_a = \dot{m}(h_2 - h_1) \longrightarrow 7.554 \text{ kW} = (1.35 \text{ kg/s})(h_2 - 125.82) \text{ kJ/kg} \longrightarrow h_2 = 131.42 \text{ kJ/kg}$$

The entropy at the exit is

$$\left. \begin{array}{l} P_2 = 4 \text{ MPa} \\ h_2 = 131.42 \text{ kJ/kg} \end{array} \right\} s_2 = 0.4423 \text{ kJ/kg.K}$$

The reversible power and the exergy destruction are

$$\begin{aligned} \dot{W}_{\text{rev}} &= \dot{m}[h_2 - h_1 - T_0(s_2 - s_1)] \\ &= (1.35 \text{ kg/s})[(131.42 - 125.82) \text{ kJ/kg} - (20 + 273 \text{ K})(0.4423 - 0.4367) \text{ kJ/kg.K}] = 5.362 \text{ kW} \end{aligned}$$

$$\dot{X}_{\text{dest}} = \dot{W}_a - \dot{W}_{\text{rev}} = 7.554 - 5.362 = \mathbf{2.193 \text{ kW}}$$

(d) The second-law efficiency is

$$\eta_{II} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_a} = \frac{5.362 \text{ kW}}{7.554 \text{ kW}} = \mathbf{0.710}$$

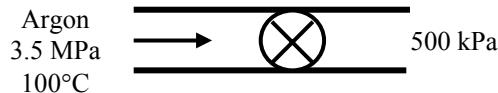

8-139 Argon gas is expanded adiabatically in an expansion valve. The exergy of argon at the inlet, the exergy destruction, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are zero. **3** Argon is an ideal gas with constant specific heats.

Properties The properties of argon gas are $R = 0.2081 \text{ kJ/kg.K}$, $c_p = 0.5203 \text{ kJ/kg.}^{\circ}\text{C}$ (Table A-2).

Analysis (a) The exergy of the argon at the inlet is

$$\begin{aligned} x_1 &= h_1 - h_0 - T_0(s_1 - s_0) \\ &= c_p(T_1 - T_0) - T_0 \left[c_p \ln \frac{T_1}{T_0} - R \ln \frac{P_1}{P_0} \right] \\ &= (0.5203 \text{ kJ/kg.K})(100 - 25)^{\circ}\text{C} - (298 \text{ K}) \left[(0.5203 \text{ kJ/kg.K}) \ln \frac{373 \text{ K}}{298 \text{ K}} - (0.2081 \text{ kJ/kg.K}) \ln \frac{3500 \text{ kPa}}{100 \text{ kPa}} \right] \\ &= \mathbf{224.7 \text{ kJ/kg}} \end{aligned}$$

(b) Noting that the temperature remains constant in a throttling process of an ideal gas, the exergy destruction is determined from

$$\begin{aligned} x_{\text{dest}} &= T_0 s_{\text{gen}} \\ &= T_0(s_2 - s_1) \\ &= T_0 \left(-R \ln \frac{P_1}{P_0} \right) = (298 \text{ K}) \left[-(0.2081 \text{ kJ/kg.K}) \ln \left(\frac{500 \text{ kPa}}{3500 \text{ kPa}} \right) \right] \\ &= \mathbf{120.7 \text{ kJ/kg}} \end{aligned}$$

(c) The second-law efficiency is

$$\eta_{\text{II}} = \frac{x_1 - x_{\text{dest}}}{x_1} = \frac{(224.7 - 120.7) \text{ kJ/kg}}{224.7 \text{ kJ/kg}} = \mathbf{0.463}$$

8-140 Heat is lost from the air flowing in a diffuser. The exit temperature, the rate of exergy destruction, and the second law efficiency are to be determined.

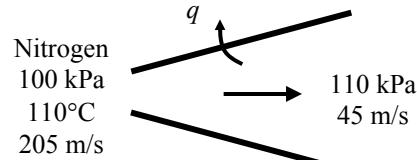

Assumptions 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Nitrogen is an ideal gas with variable specific heats.

Properties The gas constant of nitrogen is $R = 0.2968 \text{ kJ/kg.K}$.

Analysis (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure. At the inlet of the diffuser and at the dead state, we have

$$\begin{aligned} T_1 &= 110^\circ\text{C} = 383 \text{ K} \\ P_1 &= 100 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} h_1 &= 88.39 \text{ kJ/kg} \\ s_1 &= 7.101 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right\}$$

$$\begin{aligned} T_1 &= 300 \text{ K} \\ P_1 &= 100 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} h_0 &= 1.93 \text{ kJ/kg} \\ s_0 &= 6.846 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right\}$$

An energy balance on the diffuser gives

$$\begin{aligned} h_1 + \frac{V_1^2}{2} &= h_2 + \frac{V_2^2}{2} + q_{\text{out}} \\ 88.39 \text{ kJ/kg} + \frac{(205 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) &= h_2 + \frac{(45 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) + 2.5 \text{ kJ/kg} \\ \longrightarrow h_2 &= 105.9 \text{ kJ/kg} \end{aligned}$$

The corresponding properties at the exit of the diffuser are

$$\begin{aligned} h_2 &= 105.9 \text{ kJ/kg} \\ P_1 &= 110 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} T_2 &= 127^\circ\text{C} = 400 \text{ K} \\ s_2 &= 7.117 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right\}$$

(b) The mass flow rate of the nitrogen is determined to be

$$\dot{m} = \rho_2 A_2 V_2 = \frac{P_2}{RT_2} A_2 V_2 = \frac{110 \text{ kPa}}{(0.2968 \text{ kJ/kg.K})(400 \text{ K})} (0.04 \text{ m}^2)(45 \text{ m/s}) = 1.669 \text{ kg/s}$$

The exergy destruction in the nozzle is the exergy difference between the inlet and exit of the diffuser

$$\begin{aligned} \dot{X}_{\text{dest}} &= \dot{m} \left[h_1 - h_2 + \frac{V_1^2 - V_2^2}{2} - T_0(s_1 - s_2) \right] \\ &= (1.669 \text{ kg/s}) \left[(88.39 - 105.9) \text{ kJ/kg} + \frac{(205 \text{ m/s})^2 - (45 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right. \\ &\quad \left. - (300 \text{ K})(7.101 - 7.117) \text{ kJ/kg.K} \right] = 12.4 \text{ kW} \end{aligned}$$

(c) The second-law efficiency for this device may be defined as the exergy output divided by the exergy input:

$$\begin{aligned} \dot{X}_1 &= \dot{m} \left[h_1 - h_0 + \frac{V_1^2}{2} - T_0(s_1 - s_0) \right] \\ &= (1.669 \text{ kg/s}) \left[(88.39 - 1.93) \text{ kJ/kg} + \frac{(205 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) - (300 \text{ K})(7.101 - 6.846) \text{ kJ/kg.K} \right] \\ &= 51.96 \text{ kW} \\ \eta_{\text{II}} &= \frac{\dot{X}_2}{\dot{X}_1} = 1 - \frac{\dot{X}_{\text{dest}}}{\dot{X}_1} = 1 - \frac{12.4 \text{ kW}}{51.96 \text{ kW}} = 0.761 = 76.1\% \end{aligned}$$

8-141 Using an incompressible substance as an example, it is to be demonstrated if closed system and flow exergies can be negative.

Analysis The availability of a closed system cannot be negative. However, the flow availability can be negative at low pressures. A closed system has zero availability at dead state, and positive availability at any other state since we can always produce work when there is a pressure or temperature differential.

To see that the flow availability can be negative, consider an incompressible substance. The flow availability can be written as

$$\begin{aligned}\psi &= h - h_0 + T_0(s - s_0) \\ &= (u - u_0) + v(P - P_0) + T_0(s - s_0) \\ &= \xi + v(P - P_0)\end{aligned}$$

The closed system availability ξ is always positive or zero, and the flow availability can be negative when $P << P_0$.

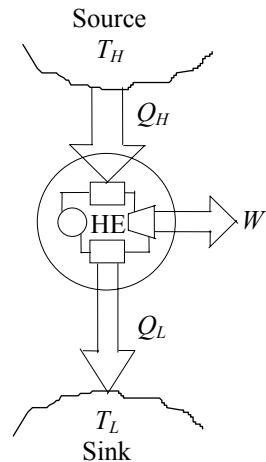

8-142 A relation for the second-law efficiency of a heat engine operating between a heat source and a heat sink at specified temperatures is to be obtained.

Analysis The second-law efficiency is defined as the ratio of the availability recovered to availability supplied during a process. The work W produced is the availability recovered. The decrease in the availability of the heat supplied Q_H is the availability supplied or invested.

Therefore,

$$\eta_{II} = \frac{W}{\left(1 - \frac{T_0}{T_H}\right)Q_H - \left(1 - \frac{T_0}{T_L}\right)(Q_H - W)}$$

Note that the first term in the denominator is the availability of heat supplied to the heat engine whereas the second term is the availability of the heat rejected by the heat engine. The difference between the two is the availability consumed during the process.

8-143 Writing energy and entropy balances, a relation for the reversible work is to be obtained for a closed system that exchanges heat with surroundings at T_0 in the amount of Q_0 as well as a heat reservoir at temperature T_R in the amount Q_R .

Assumptions Kinetic and potential changes are negligible.

Analysis We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

$$\text{Energy balance: } E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \rightarrow Q_0 + Q_R - W = U_2 - U_1 \longrightarrow W = U_1 - U_2 + Q_0 + Q_R \quad (1)$$

$$\text{Entropy balance: } S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = (S_2 - S_1) + \frac{-Q_R}{T_R} + \frac{-Q_0}{T_0} \quad (2)$$

Solving for Q_0 from (2) and substituting in (1) yields

$$W = (U_1 - U_2) - T_0(S_1 - S_2) - Q_R \left(1 - \frac{T_0}{T_R}\right) - T_0 S_{\text{gen}}$$

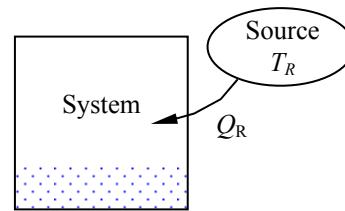

The useful work relation for a closed system is obtained from

$$\begin{aligned} W_u &= W - W_{\text{surr}} \\ &= (U_1 - U_2) - T_0(S_1 - S_2) - Q_R \left(1 - \frac{T_0}{T_R}\right) - T_0 S_{\text{gen}} - P_0(\mathbf{V}_2 - \mathbf{V}_1) \end{aligned}$$

Then the reversible work relation is obtained by substituting $S_{\text{gen}} = 0$,

$$W_{\text{rev}} = (U_1 - U_2) - T_0(S_1 - S_2) + P_0(\mathbf{V}_1 - \mathbf{V}_2) - Q_R \left(1 - \frac{T_0}{T_R}\right)$$

A positive result for W_{rev} indicates work output, and a negative result work input. Also, the Q_R is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

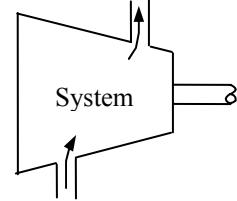

8-144 Writing energy and entropy balances, a relation for the reversible work is to be obtained for a steady-flow system that exchanges heat with surroundings at T_0 at a rate of \dot{Q}_0 as well as a heat reservoir at temperature T_R in the amount \dot{Q}_R .

Analysis We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

$$\text{Energy balance: } \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_0 + \dot{Q}_R - \dot{W} = \sum \dot{m}_e (h_e + \frac{V_e^2}{2} + gz_e) - \sum \dot{m}_i (h_i + \frac{V_i^2}{2} + gz_i)$$

$$\text{or } \dot{W} = \sum \dot{m}_i (h_i + \frac{V_i^2}{2} + gz_i) - \sum \dot{m}_e (h_e + \frac{V_e^2}{2} + gz_e) + \dot{Q}_0 + \dot{Q}_R \quad (1)$$

Entropy balance:

$$\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = \Delta \dot{S}_{\text{system}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

$$\dot{S}_{\text{gen}} = \sum \dot{m}_e s_e - \sum \dot{m}_i s_i + \frac{-\dot{Q}_R}{T_R} + \frac{-\dot{Q}_0}{T_0} \quad (2)$$

Solving for \dot{Q}_0 from (2) and substituting in (1) yields

$$\dot{W} = \sum \dot{m}_i (h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i) - \sum \dot{m}_e (h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e) - T_0 \dot{S}_{\text{gen}} - \dot{Q}_R \left(1 - \frac{T_0}{T_R} \right)$$

Then the reversible work relation is obtained by substituting $S_{\text{gen}} = 0$,

$$\dot{W}_{\text{rev}} = \sum \dot{m}_i (h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i) - \sum \dot{m}_e (h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e) - \dot{Q}_R \left(1 - \frac{T_0}{T_R} \right)$$

A positive result for W_{rev} indicates work output, and a negative result work input. Also, the Q_R is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

8-145 Writing energy and entropy balances, a relation for the reversible work is to be obtained for a uniform-flow system that exchanges heat with surroundings at T_0 in the amount of Q_0 as well as a heat reservoir at temperature T_R in the amount Q_R .

Assumptions Kinetic and potential changes are negligible.

Analysis We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

Energy balance: $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$

$$Q_0 + Q_R - W = \sum m_e (h_e + \frac{V_e^2}{2} + gz_e) - \sum m_i (h_i + \frac{V_i^2}{2} + gz_i) + (U_2 - U_1)_{cv}$$

$$\text{or, } W = \sum m_i (h_i + \frac{V_i^2}{2} + gz_i) - \sum m_e (h_e + \frac{V_e^2}{2} + gz_e) - (U_2 - U_1)_{cv} + Q_0 + Q_R \quad (1)$$

Entropy balance: $S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$

$$S_{\text{gen}} = (S_2 - S_1)_{cv} + \sum m_e s_e - \sum m_i s_i + \frac{-Q_R}{T_R} + \frac{-Q_0}{T_0} \quad (2)$$

Solving for Q_0 from (2) and substituting in (1) yields

$$\begin{aligned} W &= \sum m_i (h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i) - \sum m_e (h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e) \\ &\quad + [(U_1 - U_2) - T_0 (S_1 - S_2)]_{cv} - T_0 S_{\text{gen}} - Q_R \left(1 - \frac{T_0}{T_R} \right) \end{aligned}$$

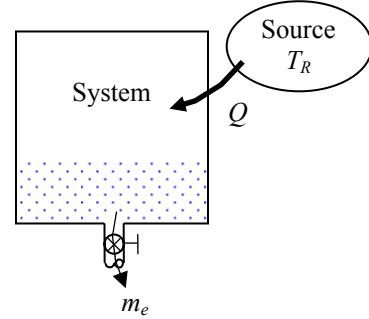

The useful work relation for a closed system is obtained from

$$\begin{aligned} W_u &= W - W_{\text{surr}} = \sum m_i (h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i) - \sum m_e (h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e) \\ &\quad + [(U_1 - U_2) - T_0 (S_1 - S_2)]_{cv} - T_0 S_{\text{gen}} - Q_R \left(1 - \frac{T_0}{T_R} \right) - P_0 (\mathbf{v}_2 - \mathbf{v}_1) \end{aligned}$$

Then the reversible work relation is obtained by substituting $S_{\text{gen}} = 0$,

$$\begin{aligned} W_{\text{rev}} &= \sum m_i (h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i) - \sum m_e (h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e) \\ &\quad + [(U_1 - U_2) - T_0 (S_1 - S_2) + P_0 (\mathbf{v}_1 - \mathbf{v}_2)]_{cv} - Q_R \left(1 - \frac{T_0}{T_R} \right) \end{aligned}$$

A positive result for W_{rev} indicates work output, and a negative result work input. Also, the Q_R is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

Fundamentals of Engineering (FE) Exam Problems

8-146 Heat is lost through a plane wall steadily at a rate of 800 W. If the inner and outer surface temperatures of the wall are 20°C and 5°C, respectively, and the environment temperature is 0°C, the rate of exergy destruction within the wall is

- (a) 40 W (b) 17,500 W (c) 765 W (d) 32,800 W (e) 0 W

Answer (a) 40 W

```
W1_ex=m*Cp*(To-T1) "Taking the energy content as the exergy content"
W2_ex=m*(Cp*(T1-To)+To*Cp*ln(T1/To)) "Using + for the second term instead of -"
W3_ex=Cp*(T1-To)-To*Cp*ln(T1/To) "Using exergy content per unit mass"
W4_ex=0 "Taking the exergy content to be zero"
```

8-152 Keeping the limitations imposed by the second-law of thermodynamics in mind, choose the wrong statement below:

- (a) A heat engine cannot have a thermal efficiency of 100%.
- (b) For all reversible processes, the second-law efficiency is 100%.
- (c) The second-law efficiency of a heat engine cannot be greater than its thermal efficiency.
- (d) The second-law efficiency of a process is 100% if no entropy is generated during that process.
- (e) The coefficient of performance of a refrigerator can be greater than 1.

Answer (c) The second-law efficiency of a heat engine cannot be greater than its thermal efficiency.

8-153 A furnace can supply heat steadily at a 1300 K at a rate of 500 kJ/s. The maximum amount of power that can be produced by using the heat supplied by this furnace in an environment at 300 K is

- (a) 115 kW
- (b) 192 kW
- (c) 385 kW
- (d) 500 kW
- (e) 650 kW

Answer (c) 385 kW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Q_in=500 "kJ/s"

Actual and Ideal Cycles, Carnot cycle, Air-Standard Assumptions, Reciprocating Engines

9-1C It is less than the thermal efficiency of a Carnot cycle.

9-2C It represents the net work on both diagrams.

9-3C The air standard assumptions are: (1) the working fluid is air which behaves as an ideal gas, (2) all the processes are internally reversible, (3) the combustion process is replaced by the heat addition process, and (4) the exhaust process is replaced by the heat rejection process which returns the working fluid to its original state.

9-4C The cold air standard assumptions involves the additional assumption that air can be treated as an ideal gas with constant specific heats at room temperature.

9-5C The clearance volume is the minimum volume formed in the cylinder whereas the displacement volume is the volume displaced by the piston as the piston moves between the top dead center and the bottom dead center.

9-6C It is the ratio of the maximum to minimum volumes in the cylinder.

9-7C The MEP is the fictitious pressure which, if acted on the piston during the entire power stroke, would produce the same amount of net work as that produced during the actual cycle.

9-8C Yes.

9-9C Assuming no accumulation of carbon deposits on the piston face, the compression ratio will remain the same (otherwise it will increase). The mean effective pressure, on the other hand, will decrease as a car gets older as a result of wear and tear.

9-10C The SI and CI engines differ from each other in the way combustion is initiated; by a spark in SI engines, and by compressing the air above the self-ignition temperature of the fuel in CI engines.

9-11C Stroke is the distance between the TDC and the BDC, bore is the diameter of the cylinder, TDC is the position of the piston when it forms the smallest volume in the cylinder, and clearance volume is the minimum volume formed in the cylinder.

9-12E The maximum possible thermal efficiency of a gas power cycle with specified reservoirs is to be determined.

Analysis The maximum efficiency this cycle can have is

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{(40 + 460) R}{(940 + 460) R} = \mathbf{0.643}$$

9-13 An air-standard cycle executed in a piston-cylinder system is composed of three specified processes. The cycle is to be sketched on the $P-v$ and $T-s$ diagrams and the back work ratio are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$.

Analysis (a) The $P-v$ and $T-s$ diagrams of the cycle are shown in the figures.

(b) Process 1-2: Isentropic compression

$$w_{1-2,in} = mc_v(T_2 - T_1)$$

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1}$$

Process 2-3: Constant pressure heat addition

$$w_{2-3,out} = \int_2^3 P dv = P_2(v_3 - v_2) = mR(T_3 - T_2)$$

The back work ratio is

$$r_{bw} = \frac{w_{1-2,in}}{w_{2-3,out}} = \frac{mc_v(T_2 - T_1)}{mR(T_3 - T_2)}$$

Noting that

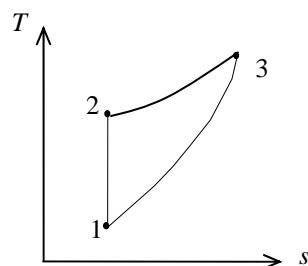

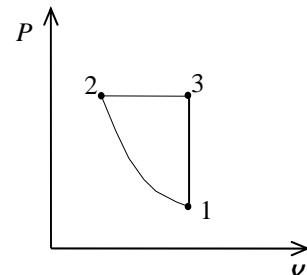

$$R = c_p - c_v \quad \text{and} \quad k = \frac{c_p}{c_v} \quad \text{and thus,} \quad c_v = \frac{R}{k-1}$$

From ideal gas relation,

$$\frac{T_3}{T_2} = \frac{v_3}{v_2} = \frac{v_1}{v_2} = r$$

Substituting these into back work relation,

$$\begin{aligned} r_{bw} &= \frac{R}{k-1} \frac{1}{R} \frac{T_2}{T_2} \frac{(1-T_1/T_2)}{(T_3/T_2 - 1)} \\ &= \frac{1}{k-1} \frac{\left(1 - \frac{1}{r^{k-1}}\right)}{r-1} = \frac{1}{k-1} \frac{\left(1 - r^{1-k}\right)}{r-1} \\ &= \frac{1}{1.4-1} \frac{\left(1 - 6^{-0.4}\right)}{6-1} \\ &= \mathbf{0.256} \end{aligned}$$

9-14 The three processes of an air-standard cycle are described. The cycle is to be shown on the P - v and T - s diagrams, and the back work ratio and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$.

Analysis (a) The P - v and T - s diagrams of the cycle are shown in the figures.

(b) The temperature at state 2 is

$$T_2 = T_1 \frac{P_2}{P_1} = (300 \text{ K}) \frac{700 \text{ kPa}}{100 \text{ kPa}} = 2100 \text{ K}$$

$$T_3 = T_2 = 2100 \text{ K}$$

During process 1-3, we have

$$\begin{aligned} w_{3-1,in} &= - \int_3^1 P d\nu = -P_1 (\nu_1 - \nu_3) = -R(T_1 - T_3) \\ &= -(0.287 \text{ kJ/kg}\cdot\text{K})(300 - 2100) \text{ K} = 516.6 \text{ kJ/kg} \end{aligned}$$

During process 2-3, we have

$$\begin{aligned} w_{2-3,out} &= \int_2^3 P d\nu = \int_2^3 \frac{RT}{\nu} d\nu = RT \ln \frac{\nu_3}{\nu_2} = RT \ln \frac{7\nu_2}{\nu_2} = RT \ln 7 \\ &= (0.287 \text{ kJ/kg}\cdot\text{K})(2100) \text{ K} \ln 7 = 1172.8 \text{ kJ/kg} \end{aligned}$$

The back work ratio is then

$$r_{bw} = \frac{w_{3-1,in}}{w_{2-3,out}} = \frac{516.6 \text{ kJ/kg}}{1172.8 \text{ kJ/kg}} = \mathbf{0.440}$$

Heat input is determined from an energy balance on the cycle during process 1-3,

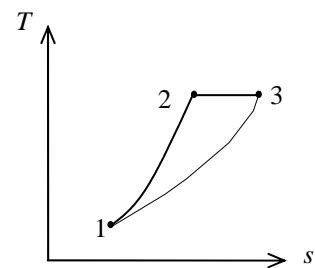

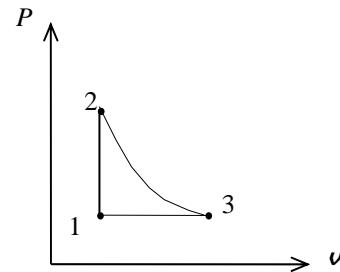

$$\begin{aligned} q_{1-3,in} - w_{2-3,out} &= \Delta u_{1-3} \\ q_{1-3,in} &= \Delta u_{1-3} + w_{2-3,out} \\ &= c_v(T_3 - T_1) + w_{2-3,out} \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(2100 - 300) + 1172.8 \text{ kJ/kg} \\ &= 2465 \text{ kJ/kg} \end{aligned}$$

The net work output is

$$w_{net} = w_{2-3,out} - w_{3-1,in} = 1172.8 - 516.6 = 656.2 \text{ kJ/kg}$$

(c) The thermal efficiency is then

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{656.2 \text{ kJ}}{2465 \text{ kJ}} = 0.266 = \mathbf{26.6\%}$$

9-15 The three processes of an ideal gas power cycle are described. The cycle is to be shown on the $P-v$ and $T-s$ diagrams, and the maximum temperature, expansion and compression works, and thermal efficiency are to be determined.

Assumptions 1 Kinetic and potential energy changes are negligible. 2 The ideal gas has constant specific heats.

Properties The properties of ideal gas are given as $R = 0.3 \text{ kJ/kg}\cdot\text{K}$, $c_p = 0.9 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.6 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.5$.

Analysis (a) The $P-v$ and $T-s$ diagrams of the cycle are shown in the figures.

(b) The maximum temperature is determined from

$$T_{\max} = T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = T_1 r^{k-1} = (27 + 273 \text{ K})(6)^{1.5-1} = \mathbf{734.8 \text{ K}}$$

(c) An energy balance during process 2-3 gives

$$\begin{aligned} q_{2-3,in} - w_{2-3,out} &= \Delta u_{2-3} = c_v(T_3 - T_2) = 0 \quad \text{since } T_3 = T_2 \\ q_{2-3,in} &= w_{2-3,out} \end{aligned}$$

Then, the work of compression is

$$\begin{aligned} q_{2-3,in} = w_{2-3,out} &= \int_2^3 P dv = \int_2^3 \frac{RT}{v} dv = RT_2 \ln \frac{V_3}{V_2} = RT_2 \ln r \\ &= (0.3 \text{ kJ/kg}\cdot\text{K})(734.8 \text{ K}) \ln 6 = \mathbf{395.0 \text{ kJ/kg}} \end{aligned}$$

(d) The work during isentropic compression is determined from an energy balance during process 1-2:

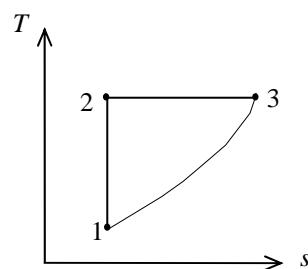

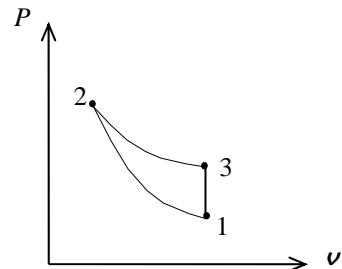

$$\begin{aligned} w_{1-2,in} &= \Delta u_{1-2} = c_v(T_2 - T_1) \\ &= (0.6 \text{ kJ/kg}\cdot\text{K})(734.8 - 300) \\ &= \mathbf{260.9 \text{ kJ/kg}} \end{aligned}$$

(e) Net work output is

$$w_{net} = w_{2-3,out} - w_{1-2,in} = 395.0 - 260.9 = 134.1 \text{ kJ/kg}$$

The thermal efficiency is then

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{134.1 \text{ kJ}}{395.0 \text{ kJ}} = 0.339 = \mathbf{33.9\%}$$

9-16 The four processes of an air-standard cycle are described. The cycle is to be shown on $P-v$ and $T-s$ diagrams, and the net work output and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (b) The properties of air at various states are

$$T_1 = 295 \text{ K} \longrightarrow h_1 = 295.17 \text{ kJ/kg}$$

$$P_{r_1} = 1.3068$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \frac{600 \text{ kPa}}{100 \text{ kPa}} (1.3068) = 7.841 \longrightarrow u_2 = 352.29 \text{ kJ/kg}$$

$$T_2 = 490.3 \text{ K}$$

$$T_3 = 1500 \text{ K} \longrightarrow u_3 = 1205.41 \text{ kJ/kg}$$

$$P_{r_3} = 601.9$$

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \frac{1500 \text{ K}}{490.3 \text{ K}} (600 \text{ kPa}) = 1835.6 \text{ kPa}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \frac{100 \text{ kPa}}{1835.6 \text{ kPa}} (601.9) = 32.79 \longrightarrow h_4 = 739.71 \text{ kJ/kg}$$

From energy balances,

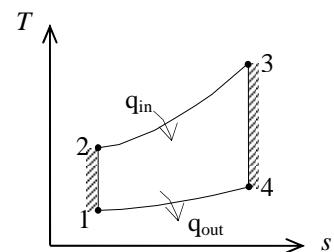

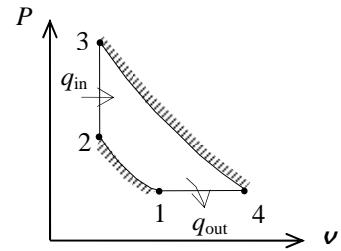

$$q_{\text{in}} = u_3 - u_2 = 1205.41 - 352.29 = 853.1 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 739.71 - 295.17 = 444.5 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 853.1 - 444.5 = \mathbf{408.6 \text{ kJ/kg}}$$

(c) Then the thermal efficiency becomes

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{408.6 \text{ kJ/kg}}{853.1 \text{ kJ/kg}} = 0.479 = \mathbf{47.9\%}$$

9-17 Problem 9-16 is reconsidered. The effect of the maximum temperature of the cycle on the net work output and thermal efficiency is to be investigated. Also, $T-s$ and $P-v$ diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

2400	50.72	1715	869.8
2500	50.95	1813	924

9-18 The three processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the heat rejected and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (b) The temperature at state 2 and the heat input are

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left(\frac{1000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 579.2 \text{ K}$$

$$Q_{\text{in}} = m(h_3 - h_2) = mc_p(T_3 - T_2)$$

$$2.76 \text{ kJ} = (0.004 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(T_3 - 579.2) \longrightarrow T_3 = 1266 \text{ K}$$

Process 3-1 is a straight line on the P - v diagram, thus the w_{31} is simply the area under the process curve,

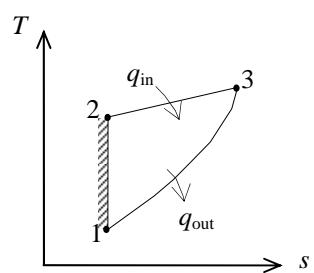

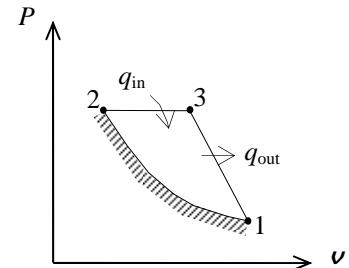

$$\begin{aligned} w_{31} &= \text{area} = \frac{P_3 + P_1}{2} (\nu_1 - \nu_3) = \frac{P_3 + P_1}{2} \left(\frac{RT_1}{P_1} - \frac{RT_3}{P_3} \right) \\ &= \left(\frac{1000 + 100 \text{ kPa}}{2} \right) \left(\frac{300 \text{ K}}{100 \text{ kPa}} - \frac{1266 \text{ K}}{1000 \text{ kPa}} \right) (0.287 \text{ kJ/kg}\cdot\text{K}) \\ &= 273.7 \text{ kJ/kg} \end{aligned}$$

Energy balance for process 3-1 gives

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \longrightarrow -Q_{31,\text{out}} - W_{31,\text{out}} = m(u_1 - u_3) \\ Q_{31,\text{out}} &= -mw_{31,\text{out}} - mc_v(T_1 - T_3) = -m[w_{31,\text{out}} + c_v(T_1 - T_3)] \\ &= -(0.004 \text{ kg})[273.7 + (0.718 \text{ kJ/kg}\cdot\text{K})(300 - 1266) \text{ K}] = \mathbf{1.679 \text{ kJ}} \end{aligned}$$

(c) The thermal efficiency is then

$$\eta_{\text{th}} = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}} = 1 - \frac{1.679 \text{ kJ}}{2.76 \text{ kJ}} = \mathbf{39.2\%}$$

9-19E The four processes of an air-standard cycle are described. The cycle is to be shown on $P-v$ and $T-s$ diagrams, and the total heat input and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (b) The properties of air at various states are

$$T_1 = 540 \text{ R} \longrightarrow u_1 = 92.04 \text{ Btu/lbm}, \quad h_1 = 129.06 \text{ Btu/lbm}$$

$$q_{\text{in},12} = u_2 - u_1 \longrightarrow u_2 = u_1 + q_{\text{in},12} = 92.04 + 300 = 392.04 \text{ Btu/lbm}$$

$$T_2 = 2116 \text{ R}, \quad h_2 = 537.1 \text{ Btu/lbm}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{2116 \text{ R}}{540 \text{ R}} (14.7 \text{ psia}) = 57.6 \text{ psia}$$

$$T_3 = 3200 \text{ R} \longrightarrow h_3 = 849.48 \text{ Btu/lbm}$$

$$P_{r_3} = 1242$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \frac{14.7 \text{ psia}}{57.6 \text{ psia}} (1242) = 317.0 \longrightarrow h_4 = 593.22 \text{ Btu/lbm}$$

From energy balance,

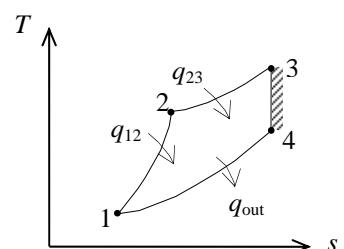

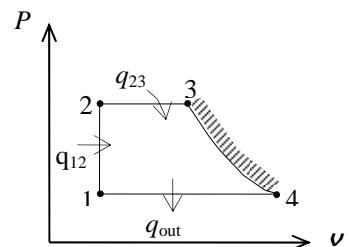

$$q_{23,\text{in}} = h_3 - h_2 = 849.48 - 537.1 = 312.38 \text{ Btu/lbm}$$

$$q_{\text{in}} = q_{12,\text{in}} + q_{23,\text{in}} = 300 + 312.38 = \mathbf{612.38 \text{ Btu/lbm}}$$

$$q_{\text{out}} = h_4 - h_1 = 593.22 - 129.06 = 464.16 \text{ Btu/lbm}$$

(c) Then the thermal efficiency becomes

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{464.16 \text{ Btu/lbm}}{612.38 \text{ Btu/lbm}} = \mathbf{24.2\%}$$

9-20E The four processes of an air-standard cycle are described. The cycle is to be shown on $P-v$ and $T-s$ diagrams, and the total heat input and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm.R}$, $c_v = 0.171 \text{ Btu/lbm.R}$, and $k = 1.4$ (Table A-2E).

Analysis (b) The temperature at state 2 and the heat input are

$$\begin{aligned} q_{\text{in},12} &= u_2 - u_1 = c_v(T_2 - T_1) \\ 300 \text{ Btu/lbm} &= (0.171 \text{ Btu/lbm.R})(T_2 - 540)\text{R} \\ T_2 &= 2294 \text{ R} \\ \frac{P_2 v_2}{T_2} &= \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{2294 \text{ R}}{540 \text{ R}} (14.7 \text{ psia}) = 62.46 \text{ psia} \\ q_{\text{in},23} &= h_3 - h_2 = c_p(T_3 - T_2) = (0.24 \text{ Btu/lbm.R})(3200 - 2294)\text{R} = 217.4 \text{ Btu/lbm} \end{aligned}$$

Process 3-4 is isentropic:

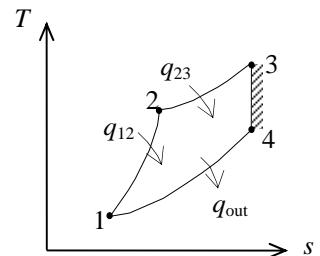

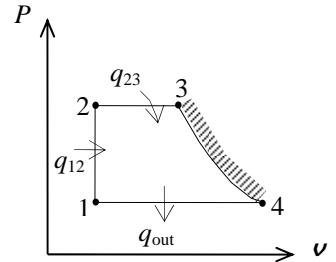

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (3200 \text{ R}) \left(\frac{14.7 \text{ psia}}{62.46 \text{ psia}} \right)^{0.4/1.4} = 2117 \text{ R}$$

$$q_{\text{in}} = q_{\text{in},12} + q_{\text{in},23} = 300 + 217.4 = \mathbf{517.4 \text{ Btu/lbm}}$$

$$q_{\text{out}} = h_4 - h_1 = c_p(T_4 - T_1) = (0.240 \text{ Btu/lbm.R})(2117 - 540) = 378.5 \text{ Btu/lbm}$$

(c) The thermal efficiency is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{378.5 \text{ Btu/lbm}}{517.4 \text{ Btu/lbm}} = \mathbf{26.8\%}$$

9-21 A Carnot cycle with the specified temperature limits is considered. The net work output per cycle is to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis The minimum pressure in the cycle is P_3 and the maximum pressure is P_1 . Then,

$$\frac{T_2}{T_3} = \left(\frac{P_2}{P_3} \right)^{(k-1)/k}$$

or

$$P_2 = P_3 \left(\frac{T_2}{T_3} \right)^{k/(k-1)} = (20 \text{ kPa}) \left(\frac{1100 \text{ K}}{300 \text{ K}} \right)^{1.4/0.4} = 1888 \text{ kPa}$$

The heat input is determined from

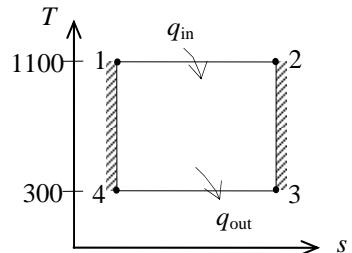

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{1888 \text{ kPa}}{3000 \text{ kPa}} = 0.1329 \text{ kJ/kg}\cdot\text{K}$$

$$Q_{\text{in}} = m T_H (s_2 - s_1) = (0.6 \text{ kg})(1100 \text{ K})(0.1329 \text{ kJ/kg}\cdot\text{K}) = 87.73 \text{ kJ}$$

Then,

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{1100 \text{ K}} = 0.7273 = 72.7\%$$

$$W_{\text{net,out}} = \eta_{\text{th}} Q_{\text{in}} = (0.7273)(87.73 \text{ kJ}) = \mathbf{63.8 \text{ kJ}}$$

9-22 A Carnot cycle executed in a closed system with air as the working fluid is considered. The minimum pressure in the cycle, the heat rejection from the cycle, the thermal efficiency of the cycle, and the second-law efficiency of an actual cycle operating between the same temperature limits are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperatures are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) The minimum temperature is determined from

$$w_{\text{net}} = (s_2 - s_1)(T_H - T_L) \longrightarrow 100 \text{ kJ/kg} = (0.25 \text{ kJ/kg}\cdot\text{K})(750 - T_L) \text{ K} \longrightarrow T_L = 350 \text{ K}$$

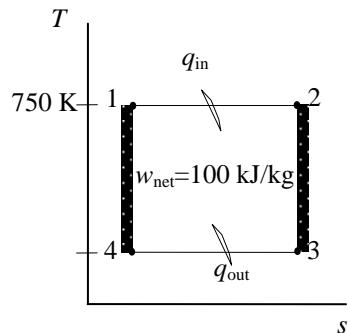

The pressure at state 4 is determined from

$$\frac{T_1}{T_4} = \left(\frac{P_1}{P_4} \right)^{(k-1)/k}$$

or

$$P_1 = P_4 \left(\frac{T_1}{T_4} \right)^{k/(k-1)}$$

$$800 \text{ kPa} = P_4 \left(\frac{750 \text{ K}}{350 \text{ K}} \right)^{1.4/0.4} \longrightarrow P_4 = 110.1 \text{ kPa}$$

The minimum pressure in the cycle is determined from

$$\Delta s_{12} = -\Delta s_{34} = c_p \ln \frac{T_4^{\phi_0}}{T_3} - R \ln \frac{P_4}{P_3}$$

$$-0.25 \text{ kJ/kg}\cdot\text{K} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{110.1 \text{ kPa}}{P_3} \longrightarrow P_3 = 46.1 \text{ kPa}$$

(b) The heat rejection from the cycle is

$$q_{\text{out}} = T_L \Delta s_{12} = (350 \text{ K})(0.25 \text{ kJ/kg}\cdot\text{K}) = 87.5 \text{ kJ/kg}$$

(c) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{350 \text{ K}}{750 \text{ K}} = 0.533$$

(d) The power output for the Carnot cycle is

$$\dot{W}_{\text{Carnot}} = \dot{m} w_{\text{net}} = (90 \text{ kg/s})(100 \text{ kJ/kg}) = 9000 \text{ kW}$$

Then, the second-law efficiency of the actual cycle becomes

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{actual}}}{\dot{W}_{\text{Carnot}}} = \frac{5200 \text{ kW}}{9000 \text{ kW}} = 0.578$$

9-23 An ideal gas Carnot cycle with air as the working fluid is considered. The maximum temperature of the low-temperature energy reservoir, the cycle's thermal efficiency, and the amount of heat that must be supplied per cycle are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The temperature of the low-temperature reservoir can be found by applying the isentropic expansion process relation

$$T_1 = T_2 \left(\frac{v_2}{v_1} \right)^{k-1} = (1027 + 273 \text{ K}) \left(\frac{1}{12} \right)^{1.4-1} = \mathbf{481.1 \text{ K}}$$

Since the Carnot engine is completely reversible, its efficiency is

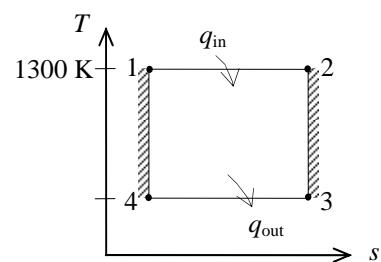

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{481.1 \text{ K}}{(1027 + 273) \text{ K}} = \mathbf{0.630}$$

The work output per cycle is

$$W_{\text{net}} = \frac{\dot{W}_{\text{net}}}{\dot{n}} = \frac{500 \text{ kJ/s}}{1500 \text{ cycle/min}} \left(\frac{60 \text{ s}}{1 \text{ min}} \right) = 20 \text{ kJ/cycle}$$

According to the definition of the cycle efficiency,

$$\eta_{\text{th,Carnot}} = \frac{W_{\text{net}}}{Q_{\text{in}}} \longrightarrow Q_{\text{in}} = \frac{W_{\text{net}}}{\eta_{\text{th,Carnot}}} = \frac{20 \text{ kJ/cycle}}{0.63} = \mathbf{31.75 \text{ kJ/cycle}}$$

9-24 An air-standard cycle executed in a piston-cylinder system is composed of three specified processes. The cycle is to be sketched on the $P-v$ and $T-s$ diagrams; the heat and work interactions and the thermal efficiency of the cycle are to be determined; and an expression for thermal efficiency as functions of compression ratio and specific heat ratio is to be obtained.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $R = 0.3 \text{ kJ/kg}\cdot\text{K}$ and $c_v = 0.3 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) The $P-v$ and $T-s$ diagrams of the cycle are shown in the figures.

(b) Noting that

$$c_p = c_v + R = 0.7 + 0.3 = 1.0 \text{ kJ/kg}\cdot\text{K}$$

$$k = \frac{c_p}{c_v} = \frac{1.0}{0.7} = 1.429$$

Process 1-2: Isentropic compression

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (293 \text{ K})(5)^{0.429} = 584.4 \text{ K}$$

$$w_{1-2,\text{in}} = c_v (T_2 - T_1) = (0.7 \text{ kJ/kg}\cdot\text{K})(584.4 - 293) \text{ K} = \mathbf{204.0 \text{ kJ/kg}}$$

$$q_{1-2} = \mathbf{0}$$

From ideal gas relation,

$$\frac{T_3}{T_2} = \frac{v_3}{v_2} = \frac{v_1}{v_2} = r \longrightarrow T_3 = (584.4)(5) = 2922$$

Process 2-3: Constant pressure heat addition

$$\begin{aligned} w_{2-3,\text{out}} &= \int_2^3 P dv = P_2 (v_3 - v_2) = R(T_3 - T_2) \\ &= (0.3 \text{ kJ/kg}\cdot\text{K})(2922 - 584.4) \text{ K} = \mathbf{701.3 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} q_{2-3,\text{in}} &= w_{2-3,\text{out}} + \Delta u_{2-3} = \Delta h_{2-3} \\ &= c_p (T_3 - T_2) = (1 \text{ kJ/kg}\cdot\text{K})(2922 - 584.4) \text{ K} = \mathbf{2338 \text{ kJ/kg}} \end{aligned}$$

Process 3-1: Constant volume heat rejection

$$q_{3-1,\text{out}} = \Delta u_{1-3} = c_v (T_3 - T_1) = (0.7 \text{ kJ/kg}\cdot\text{K})(2922 - 293) \text{ K} = \mathbf{1840.3 \text{ kJ/kg}}$$

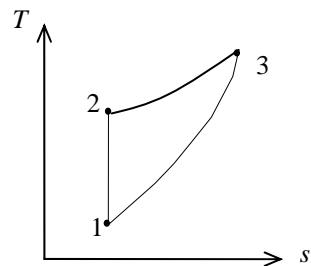

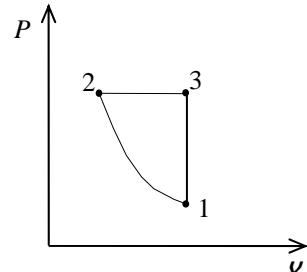

$$w_{3-1} = \mathbf{0}$$

(c) Net work is

$$w_{\text{net}} = w_{2-3,\text{out}} - w_{1-2,\text{in}} = 701.3 - 204.0 = 497.3 \text{ kJ/kg}\cdot\text{K}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{497.3 \text{ kJ}}{2338 \text{ kJ}} = 0.213 = \mathbf{21.3\%}$$

(d) The expression for the cycle thermal efficiency is obtained as follows:

$$\begin{aligned}
 \eta_{\text{th}} &= \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{w_{2-3,\text{out}} - w_{1-2,\text{in}}}{q_{\text{in}}} \\
 &= \frac{R(T_3 - T_2) - c_v(T_2 - T_1)}{c_p(T_3 - T_2)} \\
 &= \frac{R}{c_p} - \frac{c_v(T_1 r^{k-1} - T_1)}{c_p(r T_1 r^{k-1} - T_1 r^{k-1})} \\
 &= \frac{R}{c_p} - \frac{c_v T_1 r^{k-1} \left(1 - \frac{T_1}{T_1 r^{k-1}}\right)}{c_p T_1 r^{k-1} (r - 1)} \\
 &= \frac{R}{c_p} - \frac{1}{k(r-1)} \left(1 - \frac{T_1}{T_1 r^{k-1}}\right) \\
 &= \frac{R}{c_p} - \frac{1}{k(r-1)} \left(1 - \frac{1}{r^{k-1}}\right) \\
 &= \left(1 - \frac{1}{k}\right) - \frac{1}{k(r-1)} \left(1 - \frac{1}{r^{k-1}}\right)
 \end{aligned}$$

since

$$\frac{R}{c_p} = \frac{c_p - c_v}{c_p} = 1 - \frac{c_v}{c_p} = 1 - \frac{1}{k}$$

Otto Cycle

9-25C For actual four-stroke engines, the rpm is twice the number of thermodynamic cycles; for two-stroke engines, it is equal to the number of thermodynamic cycles.

9-26C The ideal Otto cycle involves external irreversibilities, and thus it has a lower thermal efficiency.

9-27C The four processes that make up the Otto cycle are (1) isentropic compression, (2) $v = \text{constant}$ heat addition, (3) isentropic expansion, and (4) $v = \text{constant}$ heat rejection.

9-28C They are analyzed as closed system processes because no mass crosses the system boundaries during any of the processes.

9-29C It increases with both of them.

9-30C Because high compression ratios cause engine knock.

9-31C The thermal efficiency will be the highest for argon because it has the highest specific heat ratio, $k = 1.667$.

9-32C The fuel is injected into the cylinder in both engines, but it is ignited with a spark plug in gasoline engines.

9-33 An ideal Otto cycle is considered. The thermal efficiency and the rate of heat input are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

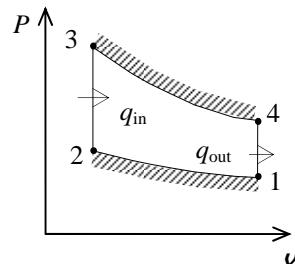

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The definition of cycle thermal efficiency reduces to

$$\eta_{th} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{10.5^{1.4-1}} = 0.6096 = \mathbf{61.0\%}$$

The rate of heat addition is then

$$\dot{Q}_{in} = \frac{\dot{W}_{net}}{\eta_{th}} = \frac{90 \text{ kW}}{0.6096} = \mathbf{148 \text{ kW}}$$

9-34 An ideal Otto cycle is considered. The thermal efficiency and the rate of heat input are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

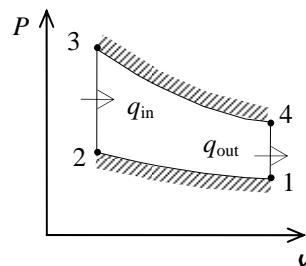

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The definition of cycle thermal efficiency reduces to

$$\eta_{th} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{8.5^{1.4-1}} = 0.5752 = \mathbf{57.5\%}$$

The rate of heat addition is then

$$\dot{Q}_{in} = \frac{\dot{W}_{net}}{\eta_{th}} = \frac{90 \text{ kW}}{0.5752} = \mathbf{157 \text{ kW}}$$

9-35 The two isentropic processes in an Otto cycle are replaced with polytropic processes. The heat added to and rejected from this cycle, and the cycle's thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

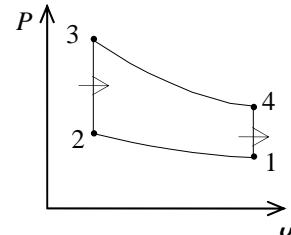

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The temperature at the end of the compression is

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{n-1} = T_1 r^{n-1} = (288 \text{ K})(8)^{1.3-1} = 537.4 \text{ K}$$

And the temperature at the end of the expansion is

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{n-1} = T_3 \left(\frac{1}{r} \right)^{n-1} = (1473 \text{ K}) \left(\frac{1}{8} \right)^{1.3-1} = 789.4 \text{ K}$$

The integral of the work expression for the polytropic compression gives

$$w_{1-2} = \frac{RT_1}{n-1} \left[\left(\frac{v_1}{v_2} \right)^{n-1} - 1 \right] = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(288 \text{ K})}{1.3-1} (8^{1.3-1} - 1) = 238.6 \text{ kJ/kg}$$

Similarly, the work produced during the expansion is

$$w_{3-4} = -\frac{RT_3}{n-1} \left[\left(\frac{v_3}{v_4} \right)^{n-1} - 1 \right] = -\frac{(0.287 \text{ kJ/kg}\cdot\text{K})(1473 \text{ K})}{1.3-1} \left[\left(\frac{1}{8} \right)^{1.3-1} - 1 \right] = 654.0 \text{ kJ/kg}$$

Application of the first law to each of the four processes gives

$$q_{1-2} = w_{1-2} - c_v(T_2 - T_1) = 238.6 \text{ kJ/kg} - (0.718 \text{ kJ/kg}\cdot\text{K})(537.4 - 288) \text{ K} = 59.53 \text{ kJ/kg}$$

$$q_{2-3} = c_v(T_3 - T_2) = (0.718 \text{ kJ/kg}\cdot\text{K})(1473 - 537.4) \text{ K} = 671.8 \text{ kJ/kg}$$

$$q_{3-4} = w_{3-4} - c_v(T_3 - T_4) = 654.0 \text{ kJ/kg} - (0.718 \text{ kJ/kg}\cdot\text{K})(1473 - 789.4) \text{ K} = 163.2 \text{ kJ/kg}$$

$$q_{4-1} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(789.4 - 288) \text{ K} = 360.0 \text{ kJ/kg}$$

The head added and rejected from the cycle are

$$q_{in} = q_{2-3} + q_{3-4} = 671.8 + 163.2 = \mathbf{835.0 \text{ kJ/kg}}$$

$$q_{out} = q_{1-2} + q_{4-1} = 59.53 + 360.0 = \mathbf{419.5 \text{ kJ/kg}}$$

The thermal efficiency of this cycle is then

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{419.5}{835.0} = \mathbf{0.498}$$

9-36 An ideal Otto cycle is considered. The heat added to and rejected from this cycle, and the cycle's thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The temperature at the end of the compression is

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (288 \text{ K})(8)^{1.4-1} = 661.7 \text{ K}$$

and the temperature at the end of the expansion is

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{1}{r} \right)^{k-1} = (1473 \text{ K}) \left(\frac{1}{8} \right)^{1.4-1} = 641.2 \text{ K}$$

Application of the first law to the heat addition process gives

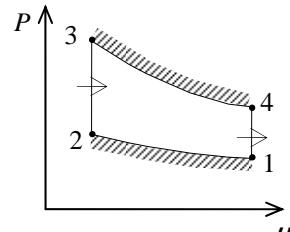

$$q_{in} = c_v (T_3 - T_2) = (0.718 \text{ kJ/kg}\cdot\text{K})(1473 - 661.7) \text{ K} = \mathbf{582.5 \text{ kJ/kg}}$$

Similarly, the heat rejected is

$$q_{out} = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(641.2 - 288) \text{ K} = \mathbf{253.6 \text{ kJ/kg}}$$

The thermal efficiency of this cycle is then

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{253.6}{582.5} = \mathbf{0.565}$$

9-37E A six-cylinder, four-stroke, spark-ignition engine operating on the ideal Otto cycle is considered. The power produced by the engine is to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

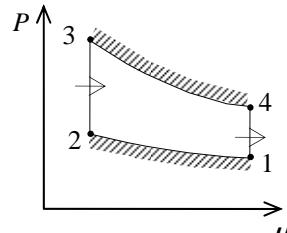

Analysis From the data specified in the problem statement,

$$r = \frac{\nu_1}{\nu_2} = \frac{\nu_1}{0.14\nu_1} = 7.143$$

Since the compression and expansion processes are isentropic,

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (525 \text{ R}) (7.143)^{1.4-1} = 1153 \text{ R}$$

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{1}{r} \right)^{k-1} = (2060 \text{ R}) \left(\frac{1}{7.143} \right)^{1.4-1} = 938.2 \text{ R}$$

Application of the first law to the compression and expansion processes gives

$$\begin{aligned} w_{\text{net}} &= c_v (T_3 - T_4) - c_v (T_2 - T_1) \\ &= (0.171 \text{ Btu/lbm} \cdot \text{R})(2060 - 938.2) \text{ R} - (0.171 \text{ Btu/lbm} \cdot \text{R})(1153 - 525) \text{ R} \\ &= 84.44 \text{ Btu/lbm} \end{aligned}$$

When each cylinder is charged with the air-fuel mixture,

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(525 \text{ R})}{14 \text{ psia}} = 13.89 \text{ ft}^3/\text{lbm}$$

The total air mass taken by all 6 cylinders when they are charged is

$$m = N_{\text{cyl}} \frac{\Delta \nu}{\nu_1} = N_{\text{cyl}} \frac{\pi B^2 S / 4}{\nu_1} = (6) \frac{\pi (3.5/12 \text{ ft})^2 (3.9/12 \text{ ft})/4}{13.89 \text{ ft}^3/\text{lbm}} = 0.009380 \text{ lbm}$$

The net work produced per cycle is

$$W_{\text{net}} = mw_{\text{net}} = (0.009380 \text{ lbm})(84.44 \text{ Btu/lbm}) = 0.7920 \text{ Btu/cycle}$$

The power produced is determined from

$$\dot{W}_{\text{net}} = \frac{W_{\text{net}} \dot{n}}{N_{\text{rev}}} = \frac{(0.7920 \text{ Btu/cycle})(2500/60 \text{ rev/s})}{2 \text{ rev/cycle}} \left(\frac{1 \text{ hp}}{0.7068 \text{ Btu/s}} \right) = 23.3 \text{ hp}$$

since there are two revolutions per cycle in a four-stroke engine.

9-38E An Otto cycle with non-isentropic compression and expansion processes is considered. The thermal efficiency, the heat addition, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis We begin by determining the temperatures of the cycle states using the process equations and component efficiencies. The ideal temperature at the end of the compression is then

$$T_{2s} = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (520 \text{ R}) (8)^{1.4-1} = 1195 \text{ R}$$

With the isentropic compression efficiency, the actual temperature at the end of the compression is

$$\eta = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta} = (520 \text{ R}) + \frac{(1195 - 520) \text{ R}}{0.85} = 1314 \text{ R}$$

Similarly for the expansion,

$$T_{4s} = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{1}{r} \right)^{k-1} = (2300 + 460 \text{ R}) \left(\frac{1}{8} \right)^{1.4-1} = 1201 \text{ R}$$

$$\eta = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta(T_3 - T_{4s}) = (2760 \text{ R}) - (0.95)(2760 - 1201) \text{ R} = 1279 \text{ R}$$

The specific heat addition is that of process 2-3,

$$q_{in} = c_v(T_3 - T_2) = (0.171 \text{ Btu/lbm} \cdot \text{R})(2760 - 1314) \text{ R} = \mathbf{247.3 \text{ Btu/lbm}}$$

The net work production is the difference between the work produced by the expansion and that used by the compression,

$$\begin{aligned} w_{net} &= c_v(T_3 - T_4) - c_v(T_2 - T_1) \\ &= (0.171 \text{ Btu/lbm} \cdot \text{R})(2760 - 1279) \text{ R} - (0.171 \text{ Btu/lbm} \cdot \text{R})(1314 - 520) \text{ R} \\ &= 117.5 \text{ Btu/lbm} \end{aligned}$$

The thermal efficiency of this cycle is then

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{117.5 \text{ Btu/lbm}}{247.3 \text{ Btu/lbm}} = \mathbf{0.475}$$

At the beginning of compression, the maximum specific volume of this cycle is

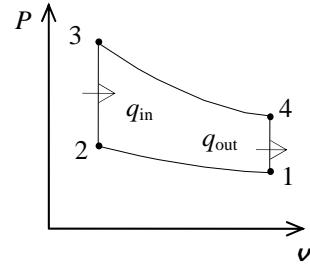

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(520 \text{ R})}{13 \text{ psia}} = 14.82 \text{ ft}^3/\text{lbm}$$

while the minimum specific volume of the cycle occurs at the end of the compression

$$\nu_2 = \frac{\nu_1}{r} = \frac{14.82 \text{ ft}^3/\text{lbm}}{8} = 1.852 \text{ ft}^3/\text{lbm}$$

The engine's mean effective pressure is then

$$\text{MEP} = \frac{w_{net}}{\nu_1 - \nu_2} = \frac{117.5 \text{ Btu/lbm}}{(14.82 - 1.852) \text{ ft}^3/\text{lbm}} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) = \mathbf{49.0 \text{ psia}}$$

9-39 An ideal Otto cycle with air as the working fluid has a compression ratio of 9.5. The highest pressure and temperature in the cycle, the amount of heat transferred, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (308 \text{ K})(9.5)^{0.4} = 757.9 \text{ K}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (9.5) \left(\frac{757.9 \text{ K}}{308 \text{ K}} \right) (100 \text{ kPa}) = 2338 \text{ kPa}$$

Process 3-4: isentropic expansion.

$$T_3 = T_4 \left(\frac{\nu_4}{\nu_3} \right)^{k-1} = (800 \text{ K})(9.5)^{0.4} = 1969 \text{ K}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \left(\frac{1969 \text{ K}}{757.9 \text{ K}} \right) (2338 \text{ kPa}) = 6072 \text{ kPa}$$

$$(b) \quad m = \frac{P_1 \nu_1}{RT_1} = \frac{(100 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(308 \text{ K})} = 6.788 \times 10^{-4} \text{ kg}$$

$$Q_{\text{in}} = m(u_3 - u_2) = mc_v(T_3 - T_2) = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(1969 - 757.9) \text{ K} = 0.590 \text{ kJ}$$

(c) Process 4-1: $\nu = \text{constant}$ heat rejection.

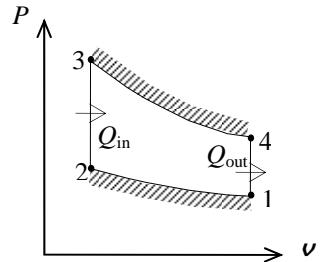

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) = -(6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(800 - 308) \text{ K} = 0.240 \text{ kJ}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 0.590 - 0.240 = 0.350 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{0.350 \text{ kJ}}{0.590 \text{ kJ}} = 59.4\%$$

$$(d) \quad \nu_{\min} = \nu_2 = \frac{\nu_{\max}}{r}$$

$$\text{MEP} = \frac{W_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{W_{\text{net,out}}}{\nu_1(1 - 1/r)} = \frac{0.350 \text{ kJ}}{(0.0006 \text{ m}^3)(1 - 1/9.5)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = 652 \text{ kPa}$$

9-40 An Otto cycle with air as the working fluid has a compression ratio of 9.5. The highest pressure and temperature in the cycle, the amount of heat transferred, the thermal efficiency, and the mean effective pressure are to be determined.

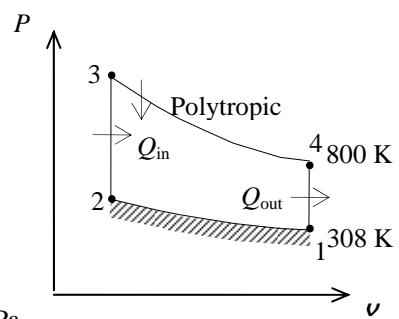

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (308 \text{ K})(9.5)^{0.4} = 757.9 \text{ K}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (9.5) \left(\frac{757.9 \text{ K}}{308 \text{ K}} \right) (100 \text{ kPa}) = 2338 \text{ kPa}$$

Process 3-4: polytropic expansion.

$$m = \frac{P_1 \nu_1}{RT_1} = \frac{(100 \text{ kPa})(0.0006 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(308 \text{ K})} = 6.788 \times 10^{-4} \text{ kg}$$

$$T_3 = T_4 \left(\frac{\nu_4}{\nu_3} \right)^{n-1} = (800 \text{ K})(9.5)^{0.35} = 1759 \text{ K}$$

$$W_{34} = \frac{mR(T_4 - T_3)}{1-n} = \frac{(6.788 \times 10^{-4} \text{ kg})(0.287 \text{ kJ/kg}\cdot\text{K})(800 - 1759) \text{ K}}{1 - 1.35} = 0.5338 \text{ kJ}$$

Then energy balance for process 3-4 gives

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$Q_{34,\text{in}} - W_{34,\text{out}} = m(u_4 - u_3)$$

$$Q_{34,\text{in}} = m(u_4 - u_3) + W_{34,\text{out}} = mc_v(T_4 - T_3) + W_{34,\text{out}}$$

$$Q_{34,\text{in}} = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(800 - 1759) \text{ K} + 0.5338 \text{ kJ} = 0.0664 \text{ kJ}$$

That is, 0.066 kJ of heat is added to the air during the expansion process (This is not realistic, and probably is due to assuming constant specific heats at room temperature).

(b) Process 2-3: $\nu = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \left(\frac{1759 \text{ K}}{757.9 \text{ K}} \right) (2338 \text{ kPa}) = 5426 \text{ kPa}$$

$$Q_{23,\text{in}} = m(u_3 - u_2) = mc_v(T_3 - T_2)$$

$$Q_{23,\text{in}} = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(1759 - 757.9) \text{ K} = 0.4879 \text{ kJ}$$

Therefore, $Q_{\text{in}} = Q_{23,\text{in}} + Q_{34,\text{in}} = 0.4879 + 0.0664 = 0.5543 \text{ kJ}$

(c) Process 4-1: $\nu = \text{constant}$ heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) = (6.788 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(800 - 308) \text{ K} = 0.2398 \text{ kJ}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 0.5543 - 0.2398 = 0.3145 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{0.3145 \text{ kJ}}{0.5543 \text{ kJ}} = 56.7\%$$

$$(d) \quad \nu_{\min} = \nu_2 = \frac{\nu_{\max}}{r}$$

$$\text{MEP} = \frac{W_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{W_{\text{net,out}}}{\nu_1(1 - 1/r)} = \frac{0.3145 \text{ kJ}}{(0.0006 \text{ m}^3)(1 - 1/9.5)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = 586 \text{ kPa}$$

9-41E An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The amount of heat transferred to the air during the heat addition process, the thermal efficiency, and the thermal efficiency of a Carnot cycle operating between the same temperature limits are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 540\text{R} \longrightarrow u_1 = 92.04\text{Btu/lbm}$$

$$\nu_{r_1} = 144.32$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_2} = \frac{1}{r} \nu_{r_2} = \frac{1}{8} (144.32) = 18.04 \longrightarrow u_2 = 211.28 \text{ Btu/lbm}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$T_3 = 2400\text{R} \longrightarrow u_3 = 452.70 \text{ Btu/lbm}$$

$$\nu_{r_3} = 2.419$$

$$q_{in} = u_3 - u_2 = 452.70 - 211.28 = \mathbf{241.42 \text{ Btu/lbm}}$$

(b) Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_4} = r \nu_{r_3} = (8)(2.419) = 19.35 \longrightarrow u_4 = 205.54 \text{ Btu/lbm}$$

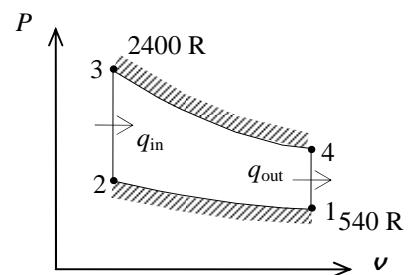

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{out} = u_4 - u_1 = 205.54 - 92.04 = 113.50 \text{ Btu/lbm}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{113.50 \text{ Btu/lbm}}{241.42 \text{ Btu/lbm}} = \mathbf{53.0\%}$$

(c) The thermal efficiency of a Carnot cycle operating between the same temperature limits is

$$\eta_{th,C} = 1 - \frac{T_L}{T_H} = 1 - \frac{540 \text{ R}}{2400 \text{ R}} = \mathbf{77.5\%}$$

9-42E An ideal Otto cycle with argon as the working fluid has a compression ratio of 8. The amount of heat transferred to the argon during the heat addition process, the thermal efficiency, and the thermal efficiency of a Carnot cycle operating between the same temperature limits are to be determined.

Assumptions 1 The air-standard assumptions are applicable with argon as the working fluid. 2 Kinetic and potential energy changes are negligible. 3 Argon is an ideal gas with constant specific heats.

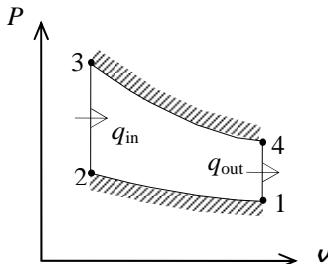

Properties The properties of argon are $c_p = 0.1253 \text{ Btu/lbm.R}$, $c_v = 0.0756 \text{ Btu/lbm.R}$, and $k = 1.667$ (Table A-2E).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (540 \text{ R}) (8)^{0.667} = 2161 \text{ R}$$

Process 2-3: $v = \text{constant}$ heat addition.

$$\begin{aligned} q_{\text{in}} &= u_3 - u_2 = c_v(T_3 - T_2) \\ &= (0.0756 \text{ Btu/lbm.R})(2400 - 2161) \text{ R} \\ &= \mathbf{18.07 \text{ Btu/lbm}} \end{aligned}$$

(b) Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = (2400 \text{ R}) \left(\frac{1}{8} \right)^{0.667} = 600 \text{ R}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v(T_4 - T_1) = (0.0756 \text{ Btu/lbm.R})(600 - 540) \text{ R} = 4.536 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{4.536 \text{ Btu/lbm}}{18.07 \text{ Btu/lbm}} = \mathbf{74.9\%}$$

(c) The thermal efficiency of a Carnot cycle operating between the same temperature limits is

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{540 \text{ R}}{2400 \text{ R}} = \mathbf{77.5\%}$$

9-43 A gasoline engine operates on an Otto cycle. The compression and expansion processes are modeled as polytropic. The temperature at the end of expansion process, the net work output, the thermal efficiency, the mean effective pressure, the engine speed for a given net power, and the specific fuel consumption are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at 850 K are $c_p = 1.110 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.823 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.349$ (Table A-2b).

Analysis (a) Process 1-2: polytropic compression

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{n-1} = (310 \text{ K})(11)^{1.3-1} = 636.5 \text{ K}$$

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^n = (100 \text{ kPa})(11)^{1.3} = 2258 \text{ kPa}$$

$$w_{12} = \frac{R(T_2 - T_1)}{1 - n} = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(636.5 - 310)\text{K}}{1 - 1.3} = -312.3 \text{ kJ/kg}$$

Process 2-3: constant volume heat addition

$$T_3 = T_2 \left(\frac{P_3}{P_2} \right) = (636.5 \text{ K}) \left(\frac{8000 \text{ kPa}}{2258 \text{ kPa}} \right) = 2255 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= u_3 - u_2 = c_v(T_3 - T_2) \\ &= (0.823 \text{ kJ/kg}\cdot\text{K})(2255 - 636.5)\text{K} = 1332 \text{ kJ/kg} \end{aligned}$$

Process 3-4: polytropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{n-1} = (2255 \text{ K}) \left(\frac{1}{11} \right)^{1.3-1} = 1098 \text{ K}$$

$$P_4 = P_3 \left(\frac{\nu_2}{\nu_1} \right)^n = (8000 \text{ kPa}) \left(\frac{1}{11} \right)^{1.3} = 354.2 \text{ kPa}$$

$$w_{34} = \frac{R(T_4 - T_3)}{1 - n} = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(1098 - 2255)\text{K}}{1 - 1.3} = 1106 \text{ kJ/kg}$$

Process 4-1: constant volume heat rejection.

(b) The net work output and the thermal efficiency are

$$w_{\text{net,out}} = w_{34} - w_{12} = 1106 - 312.3 = 794 \text{ kJ/kg}$$

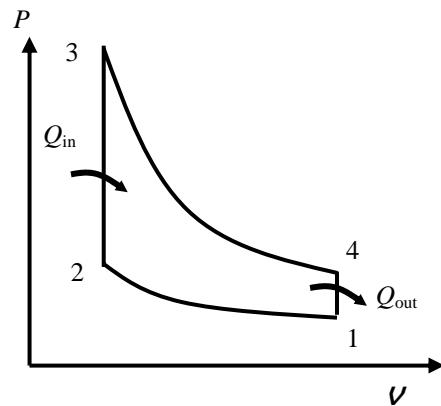

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{794 \text{ kJ/kg}}{1332 \text{ kJ/kg}} = 0.596 = 59.6\%$$

(c) The mean effective pressure is determined as follows

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(310 \text{ K})}{100 \text{ kPa}} = 0.8897 \text{ m}^3/\text{kg} = \nu_{\max}$$

$$\nu_{\min} = \nu_2 = \frac{\nu_{\max}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net,out}}}{\nu_1(1 - 1/r)} = \frac{794 \text{ kJ/kg}}{(0.8897 \text{ m}^3/\text{kg})(1 - 1/11)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = 982 \text{ kPa}$$

(d) The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{V_c + V_d}{V_c} \longrightarrow 11 = \frac{V_c + 0.0016 \text{ m}^3}{V_c} \longrightarrow V_c = 0.00016 \text{ m}^3$$

$$V_1 = V_c + V_d = 0.00016 + 0.0016 = 0.00176 \text{ m}^3$$

The total mass contained in the cylinder is

$$m_t = \frac{P_1 V_1}{RT_1} = \frac{(100 \text{ kPa}) / 0.00176 \text{ m}^3}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(310 \text{ K})} = 0.001978 \text{ kg}$$

The engine speed for a net power output of 50 kW is

$$n = 2 \frac{\dot{W}_{\text{net}}}{m_t w_{\text{net}}} = (2 \text{ rev/cycle}) \frac{50 \text{ kJ/s}}{(0.001978 \text{ kg})(794 \text{ kJ/kg} \cdot \text{cycle})} \left(\frac{60 \text{ s}}{1 \text{ min}} \right) = 3820 \text{ rev/min}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) The mass of fuel burned during one cycle is

$$\text{AF} = \frac{m_a}{m_f} = \frac{m_t - m_f}{m_f} \longrightarrow 16 = \frac{(0.001978 \text{ kg}) - m_f}{m_f} \longrightarrow m_f = 0.0001164 \text{ kg}$$

Finally, the specific fuel consumption is

$$\text{sfc} = \frac{m_f}{m_t w_{\text{net}}} = \frac{0.0001164 \text{ kg}}{(0.001978 \text{ kg})(794 \text{ kJ/kg})} \left(\frac{1000 \text{ g}}{1 \text{ kg}} \right) \left(\frac{3600 \text{ kJ}}{1 \text{ kWh}} \right) = 267 \text{ g/kWh}$$

9-44 The expressions for the maximum gas temperature and pressure of an ideal Otto cycle are to be determined when the compression ratio is doubled.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis The temperature at the end of the compression varies with the compression ratio as

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1}$$

since T_1 is fixed. The temperature rise during the combustion remains constant since the amount of heat addition is fixed. Then, the maximum cycle temperature is given by

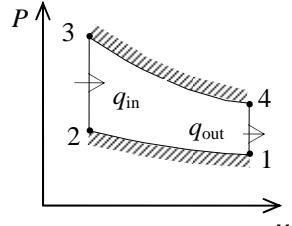

$$T_3 = q_{in} / c_v + T_2 = q_{in} / c_v + T_1 r^{k-1}$$

The smallest gas specific volume during the cycle is

$$v_3 = \frac{v_1}{r}$$

When this is combined with the maximum temperature, the maximum pressure is given by

$$P_3 = \frac{RT_3}{v_3} = \frac{Rr}{v_1} \left(q_{in} / c_v + T_1 r^{k-1} \right)$$

9-45 It is to be determined if the polytropic exponent to be used in an Otto cycle model will be greater than or less than the isentropic exponent.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis During a polytropic process,

$$Pv^n = \text{constant}$$

$$TP^{(n-1)/n} = \text{constant}$$

and for an isentropic process,

$$Pv^k = \text{constant}$$

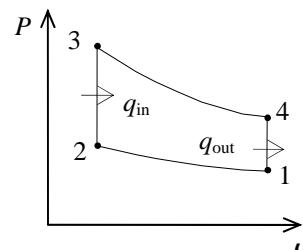

$$TP^{(k-1)/k} = \text{constant}$$

If heat is lost during the expansion of the gas,

$$T_4 > T_{4s}$$

where T_{4s} is the temperature that would occur if the expansion were reversible and adiabatic ($n=k$). This can only occur when

$$n \leq k$$

Diesel Cycle

9-46C A diesel engine differs from the gasoline engine in the way combustion is initiated. In diesel engines combustion is initiated by compressing the air above the self-ignition temperature of the fuel whereas it is initiated by a spark plug in a gasoline engine.

9-47C The Diesel cycle differs from the Otto cycle in the heat addition process only; it takes place at constant volume in the Otto cycle, but at constant pressure in the Diesel cycle.

9-48C The gasoline engine.

9-49C Diesel engines operate at high compression ratios because the diesel engines do not have the engine knock problem.

9-50C Cutoff ratio is the ratio of the cylinder volumes after and before the combustion process. As the cutoff ratio decreases, the efficiency of the diesel cycle increases.

9-51 An ideal diesel cycle has a compression ratio of 20 and a cutoff ratio of 1.3. The maximum temperature of the air and the rate of heat addition are to be determined.

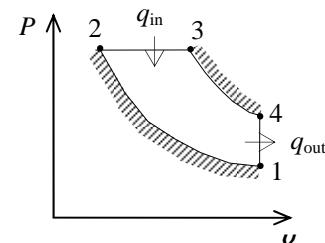

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis We begin by using the process types to fix the temperatures of the states.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (288 \text{ K})(20)^{1.4-1} = 954.6 \text{ K}$$

$$T_3 = T_2 \left(\frac{v_3}{v_2} \right) = T_2 r_c = (954.6 \text{ K})(1.3) = 1241 \text{ K}$$

Combining the first law as applied to the various processes with the process equations gives

$$\eta_{th} = 1 - \frac{1}{r^{k-1}} \frac{r_c^k - 1}{k(r_c - 1)} = 1 - \frac{1}{20^{1.4-1}} \frac{1.3^{1.4} - 1}{1.4(1.3 - 1)} = 0.6812$$

According to the definition of the thermal efficiency,

$$\dot{Q}_{in} = \frac{\dot{W}_{net}}{\eta_{th}} = \frac{250 \text{ kW}}{0.6812} = 367 \text{ kW}$$

9-52E An ideal diesel cycle has a cutoff ratio of 1.4. The power produced is to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

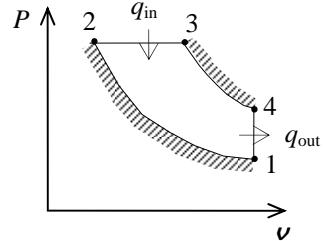

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis The specific volume of the air at the start of the compression is

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(510 \text{ R})}{14.4 \text{ psia}} = 13.12 \text{ ft}^3/\text{lbm}$$

The total air mass taken by all 8 cylinders when they are charged is

$$m = N_{\text{cyl}} \frac{\Delta V}{v_1} = N_{\text{cyl}} \frac{\pi B^2 S / 4}{v_1} = (8) \frac{\pi (4/12 \text{ ft})^2 (4/12 \text{ ft})/4}{13.12 \text{ ft}^3/\text{lbm}} = 0.01774 \text{ lbm}$$

The rate at which air is processed by the engine is determined from

$$\dot{m} = \frac{m \cdot N_{\text{rev}}}{N_{\text{rev}}} = \frac{(0.01774 \text{ lbm/cycle})(1800/60 \text{ rev/s})}{2 \text{ rev/cycle}} = 0.2661 \text{ lbm/s} = 958.0 \text{ lbm/h}$$

since there are two revolutions per cycle in a four-stroke engine. The compression ratio is

$$r = \frac{1}{0.045} = 22.22$$

At the end of the compression, the air temperature is

$$T_2 = T_1 r^{k-1} = (510 \text{ R})(22.22)^{1.4-1} = 1763 \text{ R}$$

Application of the first law and work integral to the constant pressure heat addition gives

$$q_{\text{in}} = c_p (T_3 - T_2) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2760 - 1763) \text{ R} = 239.3 \text{ Btu/lbm}$$

while the thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \frac{r_c^k - 1}{k(r_c - 1)} = 1 - \frac{1}{22.22^{1.4-1}} \frac{1.4^{1.4} - 1}{1.4(1.4 - 1)} = 0.6892$$

The power produced by this engine is then

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m} w_{\text{net}} = \dot{m} \eta_{\text{th}} q_{\text{in}} \\ &= (958.0 \text{ lbm/h})(0.6892)(239.3 \text{ Btu/lbm}) \left(\frac{1 \text{ hp}}{2544.5 \text{ Btu/h}} \right) \\ &= \mathbf{62.1 \text{ hp}} \end{aligned}$$

9-53 An ideal dual cycle has a compression ratio of 14 and cutoff ratio of 1.2. The thermal efficiency, amount of heat added, and the maximum gas pressure and temperature are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

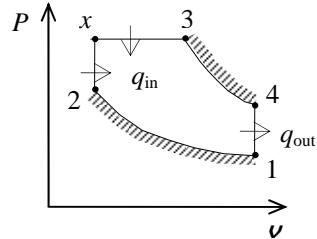

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The specific volume of the air at the start of the compression is

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{80 \text{ kPa}} = 1.051 \text{ m}^3/\text{kg}$$

and the specific volume at the end of the compression is

$$\nu_2 = \frac{\nu_1}{r} = \frac{1.051 \text{ m}^3/\text{kg}}{14} = 0.07508 \text{ m}^3/\text{kg}$$

The pressure at the end of the compression is

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^k = P_1 r^k = (80 \text{ kPa})(14)^{1.4} = 3219 \text{ kPa}$$

and the maximum pressure is

$$P_x = P_3 = r_p P_2 = (1.5)(3219 \text{ kPa}) = \mathbf{4829 \text{ kPa}}$$

The temperature at the end of the compression is

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (293 \text{ K})(14)^{1.4-1} = 842.0 \text{ K}$$

$$\text{and } T_x = T_2 \left(\frac{P_3}{P_2} \right) = (842.0 \text{ K}) \left(\frac{4829 \text{ kPa}}{3219 \text{ kPa}} \right) = 1263 \text{ K}$$

From the definition of cutoff ratio

$$\nu_3 = r_c \nu_x = r_c \nu_2 = (1.2)(0.07508 \text{ m}^3/\text{kg}) = 0.09010 \text{ m}^3/\text{kg}$$

The remaining state temperatures are then

$$T_3 = T_x \left(\frac{\nu_3}{\nu_x} \right) = (1263 \text{ K}) \left(\frac{0.09010}{0.07508} \right) = \mathbf{1516 \text{ K}}$$

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = (1516 \text{ K}) \left(\frac{0.09010}{1.051} \right)^{1.4-1} = 567.5 \text{ K}$$

Applying the first law and work expression to the heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(1263 - 842.0) \text{ K} + (1.005 \text{ kJ/kg}\cdot\text{K})(1516 - 1263) \text{ K} \\ &= \mathbf{556.5 \text{ kJ/kg}} \end{aligned}$$

The heat rejected is

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(567.5 - 293) \text{ K} = 197.1 \text{ kJ/kg}$$

$$\text{Then, } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{197.1 \text{ kJ/kg}}{556.5 \text{ kJ/kg}} = \mathbf{0.646}$$

9-54 An ideal dual cycle has a compression ratio of 14 and cutoff ratio of 1.2. The thermal efficiency, amount of heat added, and the maximum gas pressure and temperature are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis The specific volume of the air at the start of the compression is

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(253 \text{ K})}{80 \text{ kPa}} = 0.9076 \text{ m}^3/\text{kg}$$

and the specific volume at the end of the compression is

$$\nu_2 = \frac{\nu_1}{r} = \frac{0.9076 \text{ m}^3/\text{kg}}{14} = 0.06483 \text{ m}^3/\text{kg}$$

The pressure at the end of the compression is

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^k = P_1 r^k = (80 \text{ kPa})(14)^{1.4} = 3219 \text{ kPa}$$

and the maximum pressure is

$$P_x = P_3 = r_p P_2 = (1.5)(3219 \text{ kPa}) = \mathbf{4829 \text{ kPa}}$$

The temperature at the end of the compression is

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (253 \text{ K})(14)^{1.4-1} = 727.1 \text{ K}$$

$$\text{and } T_x = T_2 \left(\frac{P_3}{P_2} \right) = (727.1 \text{ K}) \left(\frac{4829 \text{ kPa}}{3219 \text{ kPa}} \right) = 1091 \text{ K}$$

From the definition of cutoff ratio

$$\nu_3 = r_c \nu_x = r_c \nu_2 = (1.2)(0.06483 \text{ m}^3/\text{kg}) = 0.07780 \text{ m}^3/\text{kg}$$

The remaining state temperatures are then

$$T_3 = T_x \left(\frac{\nu_3}{\nu_x} \right) = (1091 \text{ K}) \left(\frac{0.07780}{0.06483} \right) = \mathbf{1309 \text{ K}}$$

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = (1309 \text{ K}) \left(\frac{0.07780}{0.9076} \right)^{1.4-1} = 490.0 \text{ K}$$

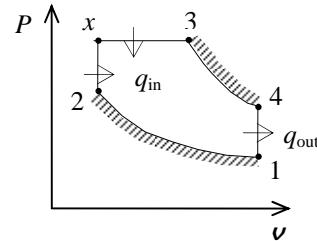

Applying the first law and work expression to the heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(1091 - 727.1) \text{ K} + (1.005 \text{ kJ/kg}\cdot\text{K})(1309 - 1091) \text{ K} \\ &= \mathbf{480.4 \text{ kJ/kg}} \end{aligned}$$

The heat rejected is

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(490.0 - 253) \text{ K} = 170.2 \text{ kJ/kg}$$

$$\text{Then, } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{170.2 \text{ kJ/kg}}{480.4 \text{ kJ/kg}} = \mathbf{0.646}$$

9-55E An air-standard Diesel cycle with a compression ratio of 18.2 is considered. The cutoff ratio, the heat rejection per unit mass, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

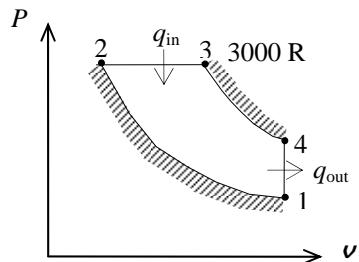

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 540 \text{ R} \longrightarrow u_1 = 92.04 \text{ Btu/lbm}$$

$$\nu_{r_1} = 144.32$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{18.2} (144.32) = 7.93 \longrightarrow T_2 = 1623.6 \text{ R}$$

$$h_2 = 402.05 \text{ Btu/lbm}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow \frac{\nu_3}{\nu_2} = \frac{T_3}{T_2} = \frac{3000 \text{ R}}{1623.6 \text{ R}} = \mathbf{1.848}$$

$$(b) \quad T_3 = 3000 \text{ R} \longrightarrow h_3 = 790.68 \text{ Btu/lbm}$$

$$\nu_{r_3} = 1.180$$

$$q_{\text{in}} = h_3 - h_2 = 790.68 - 402.05 = 388.63 \text{ Btu/lbm}$$

Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = \frac{\nu_4}{1.848 \nu_2} \nu_{r_3} = \frac{r}{1.848} \nu_{r_3} = \frac{18.2}{1.848} (1.180) = 11.621 \longrightarrow u_4 = 250.91 \text{ Btu/lbm}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 250.91 - 92.04 = \mathbf{158.87 \text{ Btu/lbm}}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{158.87 \text{ Btu/lbm}}{388.63 \text{ Btu/lbm}} = \mathbf{59.1\%}$$

9-56E An air-standard Diesel cycle with a compression ratio of 18.2 is considered. The cutoff ratio, the heat rejection per unit mass, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm.R}$, $c_v = 0.171 \text{ Btu/lbm.R}$, and $k = 1.4$ (Table A-2E).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (540 \text{ R}) (18.2)^{0.4} = 1724 \text{ R}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow \frac{\nu_3}{\nu_2} = \frac{T_3}{T_2} = \frac{3000 \text{ R}}{1724 \text{ R}} = \mathbf{1.741}$$

$$(b) q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (0.240 \text{ Btu/lbm.R})(3000 - 1724) \text{ R} = 306 \text{ Btu/lbm}$$

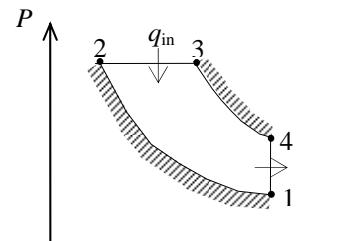

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{1.741 \nu_2}{\nu_4} \right)^{k-1} = (3000 \text{ R}) \left(\frac{1.741}{18.2} \right)^{0.4} = 1173 \text{ R}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) \\ = (0.171 \text{ Btu/lbm.R})(1173 - 540) \text{ R} = \mathbf{108 \text{ Btu/lbm}}$$

$$(c) \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{108 \text{ Btu/lbm}}{306 \text{ Btu/lbm}} = \mathbf{64.6\%}$$

9-57 An ideal diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

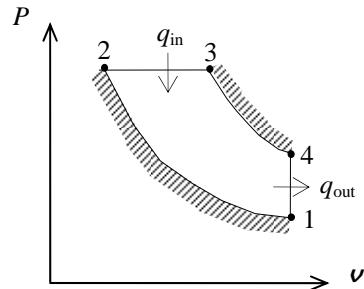

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (293 \text{ K}) (20)^{0.4} = 971.1 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 V_3}{T_3} = \frac{P_2 V_2}{T_2} \longrightarrow \frac{V_3}{V_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = T_3 \left(\frac{2.265 V_2}{V_4} \right)^{k-1} = T_3 \left(\frac{2.265}{r} \right)^{k-1} = (2200 \text{ K}) \left(\frac{2.265}{20} \right)^{0.4} = 920.6 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(920.6 - 293) \text{ K} = 450.6 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1235 - 450.6 = 784.4 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{784.4 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = 63.5\%$$

$$(b) \quad v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = v_{\max}$$

$$v_{\min} = v_2 = \frac{v_{\max}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{v_1 - v_2} = \frac{w_{\text{net,out}}}{v_1(1 - 1/r)} = \frac{784.4 \text{ kJ/kg}}{\left(0.885 \text{ m}^3/\text{kg}\right)\left(1 - 1/20\right)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = 933 \text{ kPa}$$

9-58 A diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (293 \text{ K}) (20)^{0.4} = 971.1 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 V_3}{T_3} = \frac{P_2 V_2}{T_2} \longrightarrow \frac{V_3}{V_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265$$

Process 3-4: polytropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{n-1} = T_3 \left(\frac{2.265 V_2}{V_4} \right)^{n-1} = T_3 \left(\frac{2.265}{r} \right)^{n-1} = (2200 \text{ K}) \left(\frac{2.265}{20} \right)^{0.35} = 1026 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(1026 - 293) \text{ K} = 526.3 \text{ kJ/kg}$$

Note that q_{out} in this case does not represent the entire heat rejected since some heat is also rejected during the polytropic process, which is determined from an energy balance on process 3-4:

$$w_{34,\text{out}} = \frac{R(T_4 - T_3)}{1-n} = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(1026 - 2200) \text{ K}}{1-1.35} = 963 \text{ kJ/kg}$$

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$\begin{aligned} q_{34,\text{in}} - w_{34,\text{out}} &= u_4 - u_3 \longrightarrow q_{34,\text{in}} = w_{34,\text{out}} + c_v (T_4 - T_3) \\ &= 963 \text{ kJ/kg} + (0.718 \text{ kJ/kg}\cdot\text{K})(1026 - 2200) \text{ K} \\ &= 120.1 \text{ kJ/kg} \end{aligned}$$

which means that 120.1 kJ/kg of heat is transferred to the combustion gases during the expansion process. This is unrealistic since the gas is at a much higher temperature than the surroundings, and a hot gas loses heat during polytropic expansion. The cause of this unrealistic result is the constant specific heat assumption. If we were to use u data from the air table, we would obtain

$$q_{34,\text{in}} = w_{34,\text{out}} + (u_4 - u_3) = 963 + (781.3 - 1872.4) = -128.1 \text{ kJ/kg}$$

which is a heat loss as expected. Then q_{out} becomes

$$q_{\text{out}} = q_{34,\text{out}} + q_{41,\text{out}} = 128.1 + 526.3 = 654.4 \text{ kJ/kg}$$

and

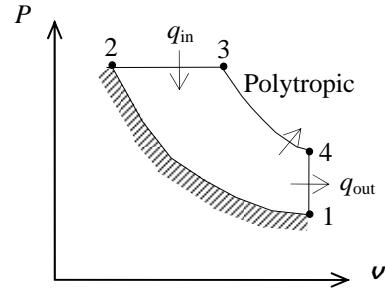

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1235 - 654.4 = 580.6 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{580.6 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = 47.0\%$$

$$(b) \quad v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{v_1 - v_2} = \frac{w_{\text{net,out}}}{v_1(1-1/r)} = \frac{580.6 \text{ kJ/kg}}{(0.885 \text{ m}^3/\text{kg})(1-1/20)} \left(\frac{1 \text{ kPa}\cdot\text{m}^3}{\text{kJ}} \right) = 691 \text{ kPa}$$

9-59 Problem 9-58 is reconsidered. The effect of the compression ratio on the net work output, mean effective pressure, and thermal efficiency is to be investigated. Also, *T-s* and *P-v* diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

```

Procedure QTotal(q_12,q_23,q_34,q_41: q_in_total,q_out_total)
q_in_total = 0
q_out_total = 0
IF (q_12 > 0) THEN q_in_total = q_12 ELSE q_out_total = - q_12
If q_23 > 0 then q_in_total = q_in_total + q_23 else q_out_total = q_out_total - q_23
If q_34 > 0 then q_in_total = q_in_total + q_34 else q_out_total = q_out_total - q_34
If q_41 > 0 then q_in_total = q_in_total + q_41 else q_out_total = q_out_total - q_41
END

9-60 A four-cylinder ideal diesel engine with air as the working fluid has a compression ratio of 22 and a cutoff ratio of 1.8. The power the engine will deliver at 2300 rpm is to be determined.

Assumptions 1 The cold air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

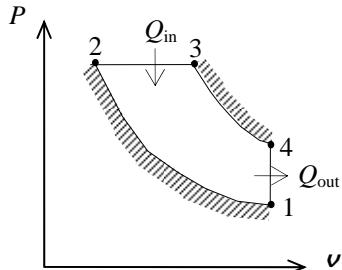

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (343 \text{ K}) (22)^{0.4} = 1181 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 V_3}{T_3} = \frac{P_2 V_2}{T_2} \longrightarrow T_3 = \frac{V_3}{V_2} T_2 = 1.8 T_2 = (1.8)(1181 \text{ K}) = 2126 \text{ K}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = T_3 \left(\frac{2.2 V_2}{V_4} \right)^{k-1} = T_3 \left(\frac{2.2}{r} \right)^{k-1} = (2126 \text{ K}) \left(\frac{1.8}{22} \right)^{0.4} = 781 \text{ K}$$

$$m = \frac{P_1 V_1}{R T_1} = \frac{(97 \text{ kPa})(0.0020 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(343 \text{ K})} = 0.001971 \text{ kg}$$

$$Q_{\text{in}} = m(h_3 - h_2) = mc_p(T_3 - T_2) \\ = (0.001971 \text{ kg})(1.005 \text{ kJ/kg} \cdot \text{K})(2126 - 1181) \text{ K} = 1.871 \text{ kJ}$$

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) \\ = (0.001971 \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(781 - 343) \text{ K} = 0.6198 \text{ kJ}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 1.871 - 0.6198 = 1.251 \text{ kJ/rev}$$

$$\dot{W}_{\text{net,out}} = \dot{n} W_{\text{net,out}} = (2300/60 \text{ rev/s})(1.251 \text{ kJ/rev}) = \mathbf{48.0 \text{ kW}}$$

Discussion Note that for 2-stroke engines, 1 thermodynamic cycle is equivalent to 1 mechanical cycle (and thus revolutions).

9-61 A four-cylinder ideal diesel engine with nitrogen as the working fluid has a compression ratio of 22 and a cutoff ratio of 1.8. The power the engine will deliver at 2300 rpm is to be determined.

Assumptions 1 The air-standard assumptions are applicable with nitrogen as the working fluid. **2** Kinetic and potential energy changes are negligible. **3** Nitrogen is an ideal gas with constant specific heats.

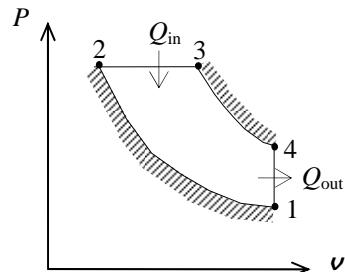

Properties The properties of nitrogen at room temperature are $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$, $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (343 \text{ K}) (22)^{0.4} = 1181 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow T_3 = \frac{\nu_3}{\nu_2} T_2 = 1.8 T_2 = (1.8)(1181 \text{ K}) = 2126 \text{ K}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{2.2 \nu_2}{\nu_4} \right)^{k-1} = T_3 \left(\frac{2.2}{r} \right)^{k-1} = (2216 \text{ K}) \left(\frac{1.8}{22} \right)^{0.4} = 781 \text{ K}$$

$$m = \frac{P_1 \nu_1}{RT_1} = \frac{(97 \text{ kPa})(0.0020 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(343 \text{ K})} = 0.001906 \text{ kg}$$

$$Q_{\text{in}} = m(h_3 - h_2) = mc_p(T_3 - T_2) \\ = (0.001906 \text{ kg})(1.039 \text{ kJ/kg} \cdot \text{K})(2216 - 1181) \text{ K} = 1.871 \text{ kJ}$$

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1) \\ = (0.001906 \text{ kg})(0.743 \text{ kJ/kg} \cdot \text{K})(781 - 343) \text{ K} = 0.6202 \text{ kJ}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 1.871 - 0.6202 = 1.251 \text{ kJ/rev}$$

$$\dot{W}_{\text{net,out}} = \dot{n} W_{\text{net,out}} = (2300/60 \text{ rev/s})(1.251 \text{ kJ/rev}) = \mathbf{47.9 \text{ kW}}$$

Discussion Note that for 2-stroke engines, 1 thermodynamic cycle is equivalent to 1 mechanical cycle (and thus revolutions).

9-62 An ideal dual cycle has a compression ratio of 18 and cutoff ratio of 1.1. The power produced by the cycle is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis We begin by fixing the temperatures at all states.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (291 \text{ K}) (18)^{1.4-1} = 924.7 \text{ K}$$

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^k = P_1 r^k = (90 \text{ kPa}) (18)^{1.4} = 5148 \text{ kPa}$$

$$P_x = P_3 = r_p P_2 = (1.1)(5148 \text{ kPa}) = 5663 \text{ kPa}$$

$$T_x = T_2 \left(\frac{P_x}{P_2} \right) = (924.7 \text{ K}) \left(\frac{5663 \text{ kPa}}{5148 \text{ kPa}} \right) = 1017 \text{ K}$$

$$T_3 = r_c T_x = (1.1)(1017 \text{ K}) = 1119 \text{ K}$$

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{r_c}{r} \right)^{k-1} = (1119 \text{ K}) \left(\frac{1.1}{18} \right)^{1.4-1} = 365.8 \text{ K}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v (T_2 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(924.7 - 291) \text{ K} = 455.0 \text{ kJ/kg}$$

$$q_{x-3} = c_p (T_3 - T_x) = (1.005 \text{ kJ/kg}\cdot\text{K})(1119 - 1017) \text{ K} = 102.5 \text{ kJ/kg}$$

$$w_{x-3} = q_{x-3} - c_v (T_3 - T_x) = 102.5 - (0.718 \text{ kJ/kg}\cdot\text{K})(1119 - 1017) \text{ K} = 29.26 \text{ kJ/kg}$$

$$w_{3-4} = c_v (T_3 - T_4) = (0.718 \text{ kJ/kg}\cdot\text{K})(1119 - 365.8) \text{ K} = 540.8 \text{ kJ/kg}$$

The net work of the cycle is

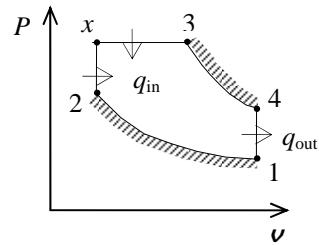

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 540.8 + 29.26 - 455.0 = 115.1 \text{ kJ/kg}$$

The mass in the device is given by

$$m = \frac{P_1 \nu_1}{RT_1} = \frac{(90 \text{ kPa})(0.003 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(291 \text{ K})} = 0.003233 \text{ kg}$$

The net power produced by this engine is then

$$\dot{W}_{\text{net}} = mw_{\text{net}} \dot{n} = (0.003233 \text{ kg/cycle})(115.1 \text{ kJ/kg})(4000/60 \text{ cycle/s}) = \mathbf{24.8 \text{ kW}}$$

9-63 A dual cycle with non-isentropic compression and expansion processes is considered. The power produced by the cycle is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis We begin by fixing the temperatures at all states.

$$T_{2s} = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (291 \text{ K})(18)^{1.4-1} = 924.7 \text{ K}$$

$$\eta = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta} = (291 \text{ K}) + \frac{(924.7 - 291) \text{ K}}{0.85} = 1037 \text{ K}$$

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^k = P_1 r^k = (90 \text{ kPa})(18)^{1.4} = 5148 \text{ kPa}$$

$$P_x = P_3 = r_p P_2 = (1.1)(5148 \text{ kPa}) = 5663 \text{ kPa}$$

$$T_x = T_2 \left(\frac{P_x}{P_2} \right) = (1037 \text{ K}) \left(\frac{5663 \text{ kPa}}{5148 \text{ kPa}} \right) = 1141 \text{ K}$$

$$T_3 = r_c T_x = (1.1)(1141 \text{ K}) = 1255 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{r_c}{r} \right)^{k-1} = (1255 \text{ K}) \left(\frac{1.1}{18} \right)^{1.4-1} = 410.3 \text{ K}$$

$$\eta = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta(T_3 - T_{4s}) = (1255 \text{ K}) - (0.90)(1255 - 410.3) \text{ K} = 494.8 \text{ K}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v(T_2 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(1037 - 291) \text{ K} = 535.6 \text{ kJ/kg}$$

$$q_{x-3} = c_p(T_3 - T_x) = (1.005 \text{ kJ/kg}\cdot\text{K})(1255 - 1141) \text{ K} = 114.6 \text{ kJ/kg}$$

$$w_{x-3} = q_{x-3} - c_v(T_3 - T_x) = 114.6 - (0.718 \text{ kJ/kg}\cdot\text{K})(1255 - 1141) \text{ K} = 32.75 \text{ kJ/kg}$$

$$w_{3-4} = c_v(T_3 - T_4) = (0.718 \text{ kJ/kg}\cdot\text{K})(1255 - 494.8) \text{ K} = 545.8 \text{ kJ/kg}$$

The net work of the cycle is

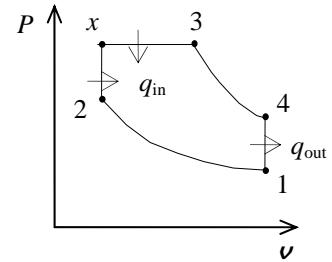

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 545.8 + 32.75 - 535.6 = 42.95 \text{ kJ/kg}$$

The mass in the device is given by

$$m = \frac{P_1 \nu_1}{RT_1} = \frac{(90 \text{ kPa})(0.003 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(291 \text{ K})} = 0.003233 \text{ kg}$$

The net power produced by this engine is then

$$\dot{W}_{\text{net}} = mw_{\text{net}} \dot{n} = (0.003233 \text{ kg/cycle})(42.95 \text{ kJ/kg})(4000/60 \text{ cycle/s}) = \mathbf{9.26 \text{ kW}}$$

9-64E An ideal dual cycle has a compression ratio of 15 and cutoff ratio of 1.4. The net work, heat addition, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$, $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis Working around the cycle, the germane properties at the various states are

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (535 \text{ R})(15)^{1.4-1} = 1580 \text{ R}$$

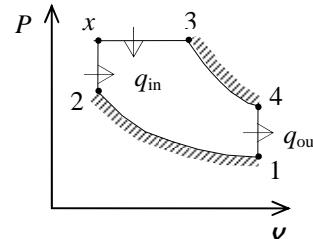

$$P_2 = P_1 \left(\frac{v_1}{v_2} \right)^k = P_1 r^k = (14.2 \text{ psia})(15)^{1.4} = 629.2 \text{ psia}$$

$$P_x = P_3 = r_p P_2 = (1.1)(629.2 \text{ psia}) = 692.1 \text{ psia}$$

$$T_x = T_2 \left(\frac{P_x}{P_2} \right) = (1580 \text{ R}) \left(\frac{692.1 \text{ psia}}{629.2 \text{ psia}} \right) = 1738 \text{ R}$$

$$T_3 = T_x \left(\frac{v_3}{v_x} \right) = T_x r_c = (1738 \text{ R})(1.4) = 2433 \text{ R}$$

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{r_c}{r} \right)^{k-1} = (2433 \text{ R}) \left(\frac{1.4}{15} \right)^{1.4-1} = 942.2 \text{ R}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v(T_2 - T_1) = (0.171 \text{ Btu/lbm}\cdot\text{R})(1580 - 535) \text{ R} = 178.7 \text{ Btu/lbm}$$

$$q_{2-x} = c_v(T_x - T_2) = (0.171 \text{ Btu/lbm}\cdot\text{R})(1738 - 1580) \text{ R} = 27.02 \text{ Btu/lbm}$$

$$q_{x-3} = c_p(T_3 - T_x) = (0.240 \text{ Btu/lbm}\cdot\text{R})(2433 - 1738) \text{ R} = 166.8 \text{ Btu/lbm}$$

$$w_{x-3} = q_{x-3} - c_v(T_3 - T_x) = 166.8 \text{ Btu/lbm} - (0.171 \text{ Btu/lbm}\cdot\text{R})(2433 - 1738) \text{ R} = 47.96 \text{ Btu/lbm}$$

$$w_{3-4} = c_v(T_3 - T_4) = (0.171 \text{ Btu/lbm}\cdot\text{R})(2433 - 942.2) \text{ R} = 254.9 \text{ Btu/lbm}$$

The net work of the cycle is

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 254.9 + 47.96 - 178.7 = \mathbf{124.2 \text{ Btu/lbm}}$$

and the net heat addition is

$$q_{\text{in}} = q_{2-x} + q_{x-3} = 27.02 + 166.8 = \mathbf{193.8 \text{ Btu/lbm}}$$

Hence, the thermal efficiency is

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{124.2 \text{ Btu/lbm}}{193.8 \text{ Btu/lbm}} = \mathbf{0.641}$$

9-65 A six-cylinder compression ignition engine operates on the ideal Diesel cycle. The maximum temperature in the cycle, the cutoff ratio, the net work output per cycle, the thermal efficiency, the mean effective pressure, the net power output, and the specific fuel consumption are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at 850 K are $c_p = 1.110 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.823 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.349$ (Table A-2b).

Analysis (a) Process 1-2: Isentropic compression

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (340 \text{ K}) (19)^{1.349-1} = 950.1 \text{ K}$$

$$P_2 = P_1 \left(\frac{v_1}{v_2} \right)^k = (95 \text{ kPa}) (19)^{1.349} = 5044 \text{ kPa}$$

The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{v_c + v_d}{v_c} \longrightarrow 19 = \frac{v_c + 0.0045 \text{ m}^3}{v_c}$$

$$v_c = 0.0001778 \text{ m}^3$$

$$v_1 = v_c + v_d = 0.0001778 + 0.0032 = 0.003378 \text{ m}^3$$

The total mass contained in the cylinder is

$$m = \frac{P_1 v_1}{R T_1} = \frac{(95 \text{ kPa})(0.003378 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(340 \text{ K})} = 0.003288 \text{ kg}$$

The mass of fuel burned during one cycle is

$$AF = \frac{m_a}{m_f} = \frac{m - m_f}{m_f} \longrightarrow 28 = \frac{(0.003288 \text{ kg}) - m_f}{m_f} \longrightarrow m_f = 0.0001134 \text{ kg}$$

Process 2-3: constant pressure heat addition

$$Q_{in} = m_f q_{HV} \eta_c = (0.0001134 \text{ kg})(42,500 \text{ kJ/kg})(0.98) = 4.723 \text{ kJ}$$

$$Q_{in} = mc_v(T_3 - T_2) \longrightarrow 4.723 \text{ kJ} = (0.003288 \text{ kg})(0.823 \text{ kJ/kg}\cdot\text{K})(T_3 - 950.1 \text{ K}) \longrightarrow T_3 = 2244 \text{ K}$$

The cutoff ratio is

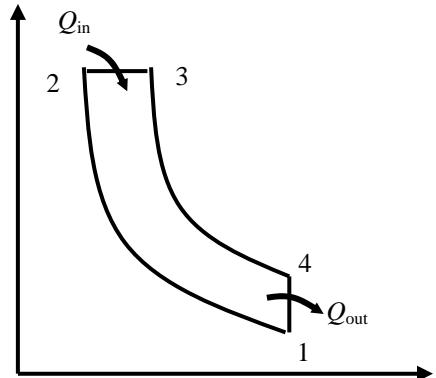

$$\beta = \frac{T_3}{T_2} = \frac{2244 \text{ K}}{950.1 \text{ K}} = 2.362$$

$$(b) \quad v_2 = \frac{v_1}{r} = \frac{0.003378 \text{ m}^3}{19} = 0.0001778 \text{ m}^3$$

$$v_3 = \beta v_2 = (2.362)(0.0001778 \text{ m}^3) = 0.0004199 \text{ m}^3$$

$$v_4 = v_1$$

$$P_3 = P_2$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = (2244 \text{ K}) \left(\frac{0.0004199 \text{ m}^3}{0.003378 \text{ m}^3} \right)^{1.349-1} = 1084 \text{ K}$$

$$P_4 = P_3 \left(\frac{V_3}{V_4} \right)^k = (5044 \text{ kPa}) \left(\frac{0.0004199 \text{ m}^3}{0.003378 \text{ m}^3} \right)^{1.349} = 302.9 \text{ kPa}$$

Process 4-1: constant volume heat rejection.

$$Q_{\text{out}} = mc_v(T_4 - T_1) = (0.003288 \text{ kg})(0.823 \text{ kJ/kg} \cdot \text{K})(1084 - 340) \text{ K} = 2.013 \text{ kJ}$$

The net work output and the thermal efficiency are

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 4.723 - 2.013 = \mathbf{2.710 \text{ kJ}}$$

$$\eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{2.710 \text{ kJ}}{4.723 \text{ kJ}} = 0.5737 = \mathbf{57.4\%}$$

(c) The mean effective pressure is determined to be

$$\text{MEP} = \frac{W_{\text{net,out}}}{V_1 - V_2} = \frac{2.710 \text{ kJ}}{(0.003378 - 0.0001778) \text{ m}^3} \left(\frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = \mathbf{847 \text{ kPa}}$$

(d) The power for engine speed of 1750 rpm is

$$\dot{W}_{\text{net}} = W_{\text{net}} \frac{\dot{n}}{2} = (2.710 \text{ kJ/cycle}) \frac{1750 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left(\frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{39.5 \text{ kW}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) Finally, the specific fuel consumption is

$$\text{sfc} = \frac{m_f}{W_{\text{net}}} = \frac{0.0001134 \text{ kg}}{2.710 \text{ kJ/kg}} \left(\frac{1000 \text{ g}}{1 \text{ kg}} \right) \left(\frac{3600 \text{ kJ}}{1 \text{ kWh}} \right) = \mathbf{151 \text{ g/kWh}}$$

9-66 An expression for cutoff ratio of an ideal diesel cycle is to be developed.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis Employing the isentropic process equations,

$$T_2 = T_1 r^{k-1}$$

while the ideal gas law gives

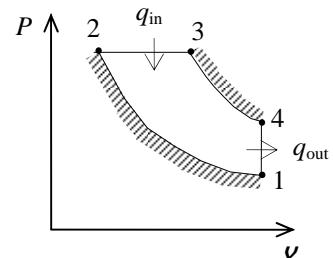

$$T_3 = T_2 r_c = r_c r^{k-1} T_1$$

When the first law and the closed system work integral is applied to the constant pressure heat addition, the result is

$$q_{in} = c_p (T_3 - T_2) = c_p (r_c r^{k-1} T_1 - r^{k-1} T_1)$$

When this is solved for cutoff ratio, the result is

$$r_c = 1 + \frac{q_{in}}{c_p r^{k-1} T_1}$$

9-67 An expression for the thermal efficiency of a dual cycle is to be developed and the thermal efficiency for a given case is to be calculated.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2)

Analysis The thermal efficiency of a dual cycle may be expressed as

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{c_v(T_4 - T_1)}{c_v(T_x - T_2) + c_p(T_3 - T_x)}$$

By applying the isentropic process relations for ideal gases with constant specific heats to the processes 1-2 and 3-4, as well as the ideal gas equation of state, the temperatures may be eliminated from the thermal efficiency expression. This yields the result

$$\eta_{th} = 1 - \frac{1}{r^{k-1}} \left[\frac{r_p r_c^k - 1}{k r_p (r_c - 1) + r_p - 1} \right]$$

where

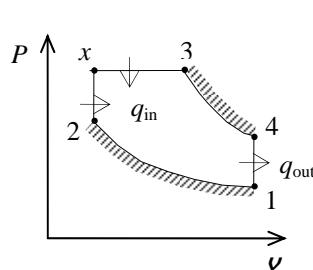

$$r_p = \frac{P_x}{P_2} \quad \text{and} \quad r_c = \frac{v_3}{v_x}$$

When $r_c = r_p$, we obtain

$$\eta_{th} = 1 - \frac{1}{r^{k-1}} \left(\frac{r_p^{k+1} - 1}{k(r_p^2 - r_p) + r_p - 1} \right)$$

For the case $r = 20$ and $r_p = 2$,

$$\eta_{th} = 1 - \frac{1}{20^{1.4-1}} \left(\frac{2^{1.4+1} - 1}{1.4(2^2 - 2) + 2 - 1} \right) = \mathbf{0.660}$$

9-68 An expression regarding the thermal efficiency of a dual cycle for a special case is to be obtained.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis The thermal efficiency of a dual cycle may be expressed as

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_v(T_4 - T_1)}{c_v(T_x - T_2) + c_p(T_3 - T_x)}$$

By applying the isentropic process relations for ideal gases with constant specific heats to the processes 1-2 and 3-4, as well as the ideal gas equation of state, the temperatures may be eliminated from the thermal efficiency expression. This yields the result

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \left[\frac{r_p r_c^k - 1}{k r_p (r_c - 1) + r_p - 1} \right]$$

where

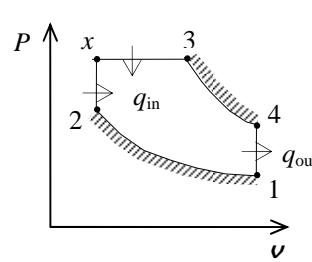

$$r_p = \frac{P_x}{P_2} \quad \text{and} \quad r_c = \frac{v_3}{v_x}$$

When $r_c = r_p$, we obtain

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \left(\frac{r_p^{k+1} - 1}{k(r_p^2 - r_p) + r_p - 1} \right)$$

Rearrangement of this result gives

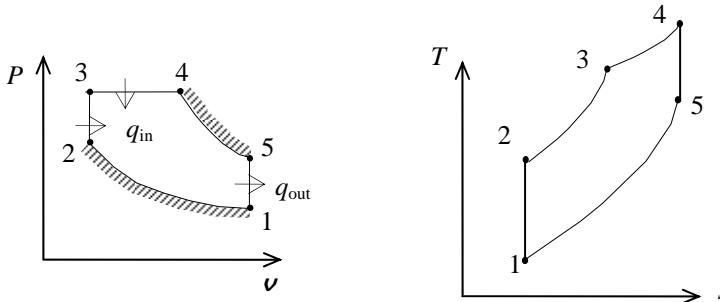

$$\frac{r_p^{k+1} - 1}{k(r_p^2 - r_p) + r_p - 1} = (1 - \eta_{\text{th}}) r^{k-1}$$

9-69 The five processes of the dual cycle is described. The $P-v$ and $T-s$ diagrams for this cycle is to be sketched. An expression for the cycle thermal efficiency is to be obtained and the limit of the efficiency is to be evaluated for certain cases.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Analysis (a) The $P-v$ and $T-s$ diagrams for this cycle are as shown.

(b) Apply first law to the closed system for processes 2-3, 3-4, and 5-1 to show:

$$q_{in} = C_v(T_3 - T_2) + C_p(T_4 - T_3)$$

$$q_{out} = C_v(T_5 - T_1)$$

The cycle thermal efficiency is given by

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{C_v(T_5 - T_1)}{C_v(T_3 - T_2) + C_p(T_4 - T_3)} = 1 - \frac{T_1(T_5/T_1 - 1)}{T_2(T_3/T_2 - 1) + kT_3(T_4/T_3 - 1)}$$

$$\eta_{th} = 1 - \frac{(T_5/T_1 - 1)}{\frac{T_2}{T_1}(T_3/T_2 - 1) + k \frac{T_3}{T_1}(T_4/T_3 - 1)}$$

Process 1-2 is isentropic; therefore,

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2} \right)^{k-1} = r^{k-1}$$

Process 2-3 is constant volume; therefore,

$$\frac{T_3}{T_2} = \frac{P_3 V_3}{P_2 V_2} = \frac{P_3}{P_2} = r_p$$

Process 3-4 is constant pressure; therefore,

$$\frac{P_4 V_4}{T_4} = \frac{P_3 V_3}{T_3} \Rightarrow \frac{T_4}{T_3} = \frac{V_4}{V_3} = r_c$$

Process 4-5 is isentropic; therefore,

$$\frac{T_5}{T_4} = \left(\frac{V_4}{V_5} \right)^{k-1} = \left(\frac{V_4}{V_1} \right)^{k-1} = \left(\frac{r_c V_3}{V_1} \right)^{k-1} = \left(\frac{r_c V_2}{V_1} \right)^{k-1} = \left(\frac{r_c}{r} \right)^{k-1}$$

Process 5-1 is constant volume; however T_5/T_1 is found from the following.

$$\frac{T_5}{T_1} = \frac{T_5}{T_4} \frac{T_4}{T_3} \frac{T_3}{T_2} \frac{T_2}{T_1} = \left(\frac{r_c}{r} \right)^{k-1} r_c r_p r^{k-1} = r_c^k r_p$$

The ratio T_3/T_1 is found from the following.

$$\frac{T_3}{T_1} = \frac{T_3}{T_2} \frac{T_2}{T_1} = r_p r^{k-1}$$

The efficiency becomes

$$\eta_{th} = 1 - \frac{r_c^k r_p - 1}{r^{k-1} (r_p - 1) + k r_p r^{k-1} (r_c - 1)}$$

(c) In the limit as r_p approaches unity, the cycle thermal efficiency becomes

$$\lim_{r_p \rightarrow 1} \eta_{th} = 1 - \left\{ \lim_{r_p \rightarrow 1} \frac{r_c^k r_p - 1}{r^{k-1} (r_p - 1) + k r_p r^{k-1} (r_c - 1)} \right\}$$

$$\lim_{r_p \rightarrow 1} \eta_{th} = 1 - \frac{1}{r^{k-1}} \left[\frac{r_c^k - 1}{k (r_c - 1)} \right] = \eta_{th \text{ Diesel}}$$

(d) In the limit as r_c approaches unity, the cycle thermal efficiency becomes

$$\lim_{r_c \rightarrow 1} \eta_{th} = 1 - \left\{ \lim_{r_c \rightarrow 1} \frac{r_c^k r_p - 1}{r^{k-1} (r_p - 1) + k r_p r^{k-1} (r_c - 1)} \right\} = 1 - \left\{ \frac{r_p - 1}{r^{k-1} (r_p - 1)} \right\}$$

$$\lim_{r_c \rightarrow 1} \eta_{th} = 1 - \frac{1}{r^{k-1}} = \eta_{th \text{ Otto}}$$

Stirling and Ericsson Cycles

9-70C The Stirling cycle.

9-71C The two isentropic processes of the Carnot cycle are replaced by two constant pressure regeneration processes in the Ericsson cycle.

9-72C The efficiencies of the Carnot and the Stirling cycles would be the same, the efficiency of the Otto cycle would be less.

9-73C The efficiencies of the Carnot and the Ericsson cycles would be the same, the efficiency of the Diesel cycle would be less.

9-74 An ideal steady-flow Ericsson engine with air as the working fluid is considered. The maximum pressure in the cycle, the net work output, and the thermal efficiency of the cycle are to be determined.

Assumptions Air is an ideal gas.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) The entropy change during process 3-4 is

$$s_4 - s_3 = -\frac{q_{34,\text{out}}}{T_0} = -\frac{150 \text{ kJ/kg}}{300 \text{ K}} = -0.5 \text{ kJ/kg}\cdot\text{K}$$

and

$$\begin{aligned} s_4 - s_3 &= c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} \\ &= -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{P_4}{120 \text{ kPa}} = -0.5 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

It yields $P_4 = 685.2 \text{ kPa}$

(b) For reversible cycles,

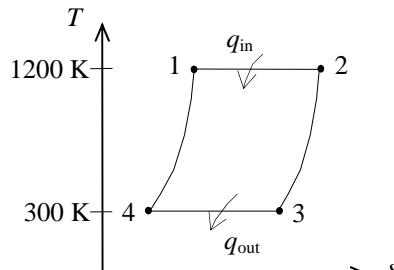

$$\frac{q_{\text{out}}}{q_{\text{in}}} = \frac{T_L}{T_H} \longrightarrow q_{\text{in}} = \frac{T_H}{T_L} q_{\text{out}} = \frac{1200 \text{ K}}{300 \text{ K}} (150 \text{ kJ/kg}) = 600 \text{ kJ/kg}$$

Thus,

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 600 - 150 = 450 \text{ kJ/kg}$$

(c) The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{1200 \text{ K}} = 75.0\%$$

9-75 An ideal Stirling engine with air as the working fluid operates between the specified temperature and pressure limits. The net work produced per cycle and the thermal efficiency of the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis Since the specific volume is constant during process 2-3,

$$P_2 = P_3 \frac{T_2}{T_3} = (100 \text{ kPa}) \left(\frac{800 \text{ K}}{300 \text{ K}} \right) = 266.7 \text{ kPa}$$

Heat is only added to the system during reversible process 1-2. Then,

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= 0 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \left(\frac{266.7 \text{ kPa}}{2000 \text{ kPa}} \right) \\ &= 0.5782 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

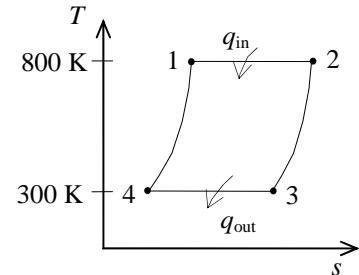

$$q_{\text{in}} = T_1(s_2 - s_1) = (800 \text{ K})(0.5782 \text{ kJ/kg}\cdot\text{K}) = 462.6 \text{ kJ/kg}$$

The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{800 \text{ K}} = \mathbf{0.625}$$

Then,

$$W_{\text{net}} = \eta_{\text{th}} m q_{\text{in}} = (0.625)(1 \text{ kg})(462.6 \text{ kJ/kg}) = \mathbf{289.1 \text{ kJ}}$$

9-76 An ideal Stirling engine with air as the working fluid operates between the specified temperature and pressure limits. The power produced and the rate of heat input are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis Since the specific volume is constant during process 2-3,

$$P_2 = P_3 \frac{T_2}{T_3} = (100 \text{ kPa}) \left(\frac{800 \text{ K}}{300 \text{ K}} \right) = 266.7 \text{ kPa}$$

Heat is only added to the system during reversible process 1-2. Then,

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= 0 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \left(\frac{266.7 \text{ kPa}}{2000 \text{ kPa}} \right) \\ &= 0.5782 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$q_{\text{in}} = T_1(s_2 - s_1) = (800 \text{ K})(0.5782 \text{ kJ/kg}\cdot\text{K}) = 462.6 \text{ kJ/kg}$$

The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{800 \text{ K}} = 0.625$$

Then,

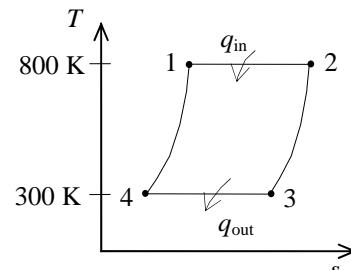

$$W_{\text{net}} = \eta_{\text{th}} m q_{\text{in}} = (0.625)(1 \text{ kg})(462.6 \text{ kJ/kg}) = 289.1 \text{ kJ}$$

The rate at which heat is added to this engine is

$$\dot{Q}_{\text{in}} = mq_{\text{in}}\dot{n} = (1 \text{ kg}/\text{cycle})(462.6 \text{ kJ/kg})(1300/60 \text{ cycle/s}) = \mathbf{10,020 \text{ kW}}$$

while the power produced by the engine is

$$\dot{W}_{\text{net}} = W_{\text{net}}\dot{n} = (289.1 \text{ kJ/cycle})(1300/60 \text{ cycle/s}) = \mathbf{6264 \text{ kW}}$$

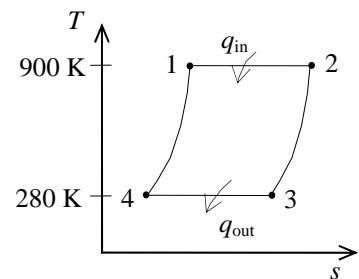

9-77 An ideal Ericsson cycle operates between the specified temperature limits. The rate of heat addition is to be determined.

Analysis The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{th} = 1 - \frac{T_L}{T_H} = 1 - \frac{280 \text{ K}}{900 \text{ K}} = 0.6889$$

According to the general definition of the thermal efficiency, the rate of heat addition is

$$\dot{Q}_{in} = \frac{\dot{W}_{net}}{\eta_{th}} = \frac{500 \text{ kW}}{0.6889} = 726 \text{ kW}$$

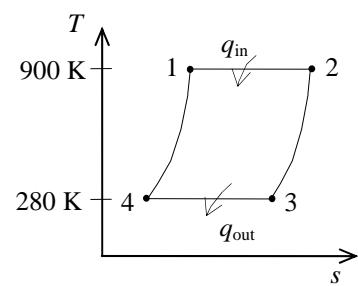

9-78 An ideal Ericsson cycle operates between the specified temperature limits. The power produced by the cycle is to be determined.

Analysis The power output is 500 kW when the cycle is repeated 2000 times per minute. Then the work per cycle is

$$W_{net} = \frac{\dot{W}_{net}}{\dot{n}} = \frac{500 \text{ kJ/s}}{(2000/60) \text{ cycle/s}} = 15 \text{ kJ/cycle}$$

When the cycle is repeated 3000 times per minute, the power output will be

$$\dot{W}_{net} = \dot{n} W_{net} = (3000/60 \text{ cycle/s})(15 \text{ kJ/cycle}) = 750 \text{ kW}$$

9-79E An ideal Stirling engine with air as the working fluid is considered. The temperature of the source-energy reservoir, the amount of air contained in the engine, and the maximum air pressure during the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis From the thermal efficiency relation,

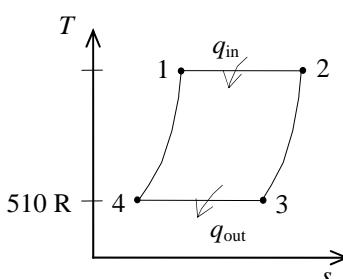

$$\eta_{th} = \frac{W_{net}}{Q_{in}} = 1 - \frac{T_L}{T_H} \longrightarrow \frac{2 \text{ Btu}}{6 \text{ Btu}} = 1 - \frac{510 \text{ R}}{T_H} \longrightarrow T_H = 765 \text{ R}$$

State 3 may be used to determine the mass of air in the system,

$$m = \frac{P_3 V_3}{RT_3} = \frac{(10 \text{ psia})(0.5 \text{ ft}^3)}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(510 \text{ R})} = 0.02647 \text{ lbm}$$

The maximum pressure occurs at state 1,

$$P_1 = \frac{mRT_1}{V_1} = \frac{(0.02647 \text{ lbm})(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(765 \text{ R})}{0.06 \text{ ft}^3} = 125 \text{ psia}$$

9-80E An ideal Stirling engine with air as the working fluid is considered. The temperature of the source-energy reservoir, the amount of air contained in the engine, and the maximum air pressure during the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$, $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu/lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2E).

Analysis From the thermal efficiency relation,

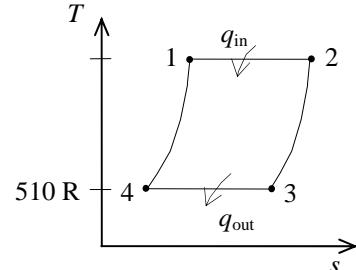

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = 1 - \frac{T_L}{T_H} \longrightarrow \frac{2.5 \text{ Btu}}{6 \text{ Btu}} = 1 - \frac{510 \text{ R}}{T_H} \longrightarrow T_H = 874 \text{ R}$$

State 3 may be used to determine the mass of air in the system,

$$m = \frac{P_3 V_3}{RT_3} = \frac{(10 \text{ psia})(0.5 \text{ ft}^3)}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(510 \text{ R})} = 0.02647 \text{ lbm}$$

The maximum pressure occurs at state 1,

$$P_1 = \frac{mRT_1}{V_1} = \frac{(0.02647 \text{ lbm})(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(874 \text{ R})}{0.06 \text{ ft}^3} = 143 \text{ psia}$$

9-81 An ideal Stirling engine with air as the working fluid operates between specified pressure limits. The heat added to the cycle and the net work produced by the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$, $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$, and $k = 1.4$ (Table A-2a).

Analysis Applying the ideal gas equation to the isothermal process 3-4 gives

$$P_4 = P_3 \frac{V_3}{V_4} = (50 \text{ kPa})(12) = 600 \text{ kPa}$$

Since process 4-1 is one of constant volume,

$$T_1 = T_4 \left(\frac{P_1}{P_4} \right) = (298 \text{ K}) \left(\frac{3600 \text{ kPa}}{600 \text{ kPa}} \right) = 1788 \text{ K}$$

Adapting the first law and work integral to the heat addition process gives

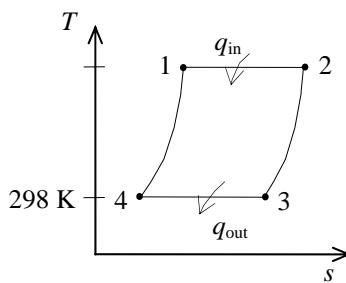

$$q_{\text{in}} = w_{1-2} = RT_1 \ln \frac{V_2}{V_1} = (0.287 \text{ kJ/kg} \cdot \text{K})(1788 \text{ K}) \ln(12) = 1275 \text{ kJ/kg}$$

Similarly,

$$q_{\text{out}} = w_{3-4} = RT_3 \ln \frac{V_4}{V_3} = (0.287 \text{ kJ/kg} \cdot \text{K})(298 \text{ K}) \ln \left(\frac{1}{12} \right) = 212.5 \text{ kJ/kg}$$

The net work is then

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1275 - 212.5 = 1063 \text{ kJ/kg}$$

9-82 An ideal Stirling engine with air as the working fluid operates between specified pressure limits. The heat transfer in the regenerator is to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis Applying the ideal gas equation to the isothermal process 3-4 gives

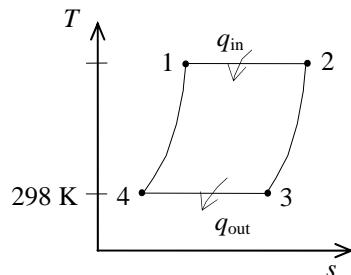

$$P_4 = P_3 \frac{v_3}{v_4} = (50 \text{ kPa})(12) = 600 \text{ kPa}$$

Since process 4-1 is one of constant volume,

$$T_1 = T_4 \left(\frac{P_1}{P_4} \right) = (298 \text{ K}) \left(\frac{3600 \text{ kPa}}{600 \text{ kPa}} \right) = 1788 \text{ K}$$

Application of the first law to process 4-1 gives

$$q_{\text{regen}} = c_v(T_1 - T_4) = (0.718 \text{ kJ/kg}\cdot\text{K})(1788 - 298)\text{K} = \mathbf{1070 \text{ kJ/kg}}$$

Ideal and Actual Gas-Turbine (Brayton) Cycles

9-83C They are (1) isentropic compression (in a compressor), (2) $P = \text{constant}$ heat addition, (3) isentropic expansion (in a turbine), and (4) $P = \text{constant}$ heat rejection.

9-84C For fixed maximum and minimum temperatures, (a) the thermal efficiency increases with pressure ratio, (b) the net work first increases with pressure ratio, reaches a maximum, and then decreases.

9-85C Back work ratio is the ratio of the compressor (or pump) work input to the turbine work output. It is usually between 0.40 and 0.6 for gas turbine engines.

9-86C In gas turbine engines a gas is compressed, and thus the compression work requirements are very large since the steady-flow work is proportional to the specific volume.

9-87C As a result of turbine and compressor inefficiencies, (a) the back work ratio increases, and (b) the thermal efficiency decreases.

9-88E A simple ideal Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the compressor exit, the back work ratio, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (a) Noting that process 1-2 is isentropic,

$$T_1 = 520 \text{ R} \longrightarrow h_1 = 124.27 \text{ Btu/lbm}$$

$$P_{r_1} = 1.2147$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (10)(1.2147) = 12.147 \longrightarrow T_2 = 996.5 \text{ R}$$

$$h_2 = 240.11 \text{ Btu/lbm}$$

(b) Process 3-4 is isentropic, and thus

$$T_3 = 2000 \text{ R} \longrightarrow h_3 = 504.71 \text{ Btu/lbm}$$

$$P_{r_3} = 174.0$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{10}\right)(174.0) = 17.4 \longrightarrow h_4 = 265.83 \text{ Btu/lbm}$$

$$w_{C,in} = h_2 - h_1 = 240.11 - 124.27 = 115.84 \text{ Btu/lbm}$$

$$w_{T,out} = h_3 - h_4 = 504.71 - 265.83 = 238.88 \text{ Btu/lbm}$$

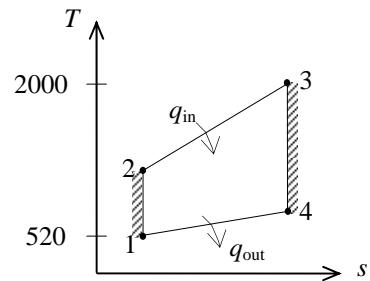

Then the back-work ratio becomes

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{115.84 \text{ Btu/lbm}}{238.88 \text{ Btu/lbm}} = 48.5\%$$

(c) $q_{in} = h_3 - h_2 = 504.71 - 240.11 = 264.60 \text{ Btu/lbm}$

$$w_{net,out} = w_{T,out} - w_{C,in} = 238.88 - 115.84 = 123.04 \text{ Btu/lbm}$$

$$\eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{123.04 \text{ Btu/lbm}}{264.60 \text{ Btu/lbm}} = 46.5\%$$

- 9-89** A simple Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (a) Noting that process 1-2s is isentropic,

$$T_1 = 295 \text{ K} \longrightarrow h_1 = 295.17 \text{ kJ/kg}$$

$$P_{r_1} = 1.3068$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (10)(1.3068) = 13.07 \longrightarrow h_{2s} = 570.26 \text{ kJ/kg} \text{ and } T_{2s} = 564.9 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C}$$

$$= 295.17 + \frac{570.26 - 295.17}{0.83} = 626.60 \text{ kJ/kg}$$

$$T_3 = 1240 \text{ K} \longrightarrow h_3 = 1324.93 \text{ kJ/kg}$$

$$P_{r_3} = 272.3$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{10}\right)(272.3) = 27.23 \longrightarrow h_{4s} = 702.07 \text{ kJ/kg} \text{ and } T_{4s} = 689.6 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s})$$

$$= 1324.93 - (0.87)(1324.93 - 702.07)$$

$$= 783.04 \text{ kJ/kg}$$

Thus,

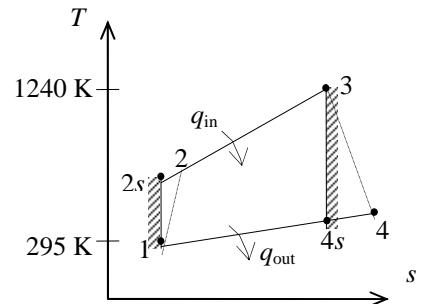

$$T_4 = \mathbf{764.4 \text{ K}}$$

$$(b) q_{in} = h_3 - h_2 = 1324.93 - 626.60 = 698.3 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = 783.04 - 295.17 = 487.9 \text{ kJ/kg}$$

$$w_{net,out} = q_{in} - q_{out} = 698.3 - 487.9 = \mathbf{210.4 \text{ kJ/kg}}$$

$$(c) \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{210.4 \text{ kJ/kg}}{698.3 \text{ kJ/kg}} = 0.3013 = \mathbf{30.1\%}$$

9-90 Problem 9-89 is reconsidered. The mass flow rate, pressure ratio, turbine inlet temperature, and the isentropic efficiencies of the turbine and compressor are to be varied and a general solution for the problem by taking advantage of the diagram window method for supplying data to EES is to be developed.

Analysis Using EES, the problem is solved as follows:

```

9-91 A simple Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) Using the compressor and turbine efficiency relations,

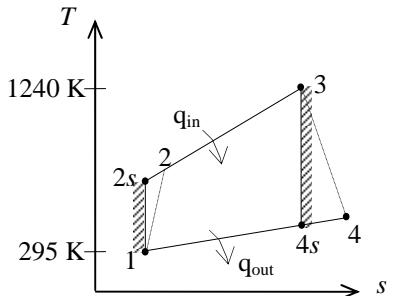

$$\begin{aligned} T_{2s} &= T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (295 \text{ K})(10)^{0.4/1.4} = 569.6 \text{ K} \\ T_{4s} &= T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1240 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 642.3 \text{ K} \\ \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \rightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C} \\ &= 295 + \frac{569.6 - 295}{0.83} = 625.8 \text{ K} \\ \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \rightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s}) \\ &= 1240 - (0.87)(1240 - 642.3) \\ &= \mathbf{720 \text{ K}} \end{aligned}$$

$$(b) \quad q_{in} = h_3 - h_2 = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(1240 - 625.8) \text{ K} = 617.3 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = c_p(T_4 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(720 - 295) \text{ K} = 427.1 \text{ kJ/kg}$$

$$w_{net,out} = q_{in} - q_{out} = 617.3 - 427.1 = \mathbf{190.2 \text{ kJ/kg}}$$

$$(c) \quad \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{190.2 \text{ kJ/kg}}{617.3 \text{ kJ/kg}} = 0.3081 = \mathbf{30.8\%}$$

9-92E A simple ideal Brayton cycle with helium has a pressure ratio of 14. The power output is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Helium is an ideal gas with constant specific heats.

Properties The properties of helium are $c_p = 1.25 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.667$ (Table A-2Ea).

Analysis Using the isentropic relations for an ideal gas,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 r_p^{(k-1)/k} = (520 \text{ R})(14)^{0.667/1.667} = 1495 \text{ R}$$

Similarly,

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1760 \text{ R}) \left(\frac{1}{14} \right)^{0.667/1.667} = 612.2 \text{ K}$$

Applying the first law to the constant-pressure heat addition process 2-3 produces

$$q_{\text{in}} = c_p (T_3 - T_2) = (1.25 \text{ Btu/lbm}\cdot\text{R})(1760 - 1495) \text{ R} = 331.3 \text{ Btu/lbm}$$

Similarly,

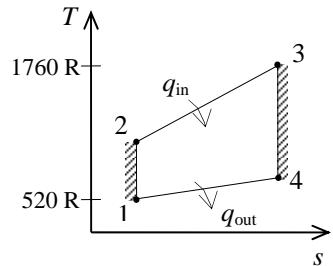

$$q_{\text{out}} = c_p (T_4 - T_1) = (1.25 \text{ Btu/lbm}\cdot\text{R})(612.2 - 520) \text{ R} = 115.3 \text{ Btu/lbm}$$

The net work production is then

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 331.3 - 115.3 = 216.0 \text{ Btu/lbm}$$

and

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (100 \text{ lbm/min})(216.0 \text{ Btu/lbm}) \left(\frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) = \mathbf{509.3 \text{ hp}}$$

9-93E A simple Brayton cycle with helium has a pressure ratio of 14. The power output is to be determined.

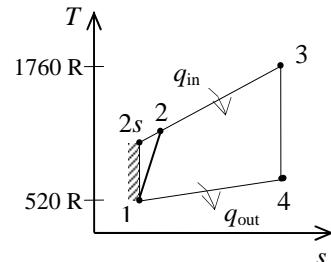

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Helium is an ideal gas with constant specific heats.

Properties The properties of helium at room temperature are $c_p = 1.25 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.667$ (Table A-2Ea).

Analysis For the compression process,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 r_p^{(k-1)/k} = (520 \text{ R}) (14)^{0.667/1.667} = 1495 \text{ R}$$

$$\begin{aligned} \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C} \\ &= 520 + \frac{1495 - 520}{0.95} = 1546 \text{ R} \end{aligned}$$

For the isentropic expansion process,

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1760 \text{ R}) \left(\frac{1}{14} \right)^{0.667/1.667} = 612.2 \text{ R}$$

Applying the first law to the constant-pressure heat addition process 2-3 produces

$$q_{in} = c_p(T_3 - T_2) = (1.25 \text{ Btu/lbm}\cdot\text{R})(1760 - 1546) \text{ R} = 267.5 \text{ Btu/lbm}$$

Similarly,

$$q_{out} = c_p(T_4 - T_1) = (1.25 \text{ Btu/lbm}\cdot\text{R})(612.2 - 520) \text{ R} = 115.3 \text{ Btu/lbm}$$

The net work production is then

$$w_{net} = q_{in} - q_{out} = 267.5 - 115.3 = 152.2 \text{ Btu/lbm}$$

and

$$\dot{W}_{net} = \dot{m} w_{net} = (100 \text{ lbm/min})(152.2 \text{ Btu/lbm}) \left(\frac{1 \text{ hp}}{42.41 \text{ Btu/min}} \right) = \mathbf{358.9 \text{ hp}}$$

9-94 A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The effects of non-isentropic compressor and turbine on the back-work ratio is to be compared.

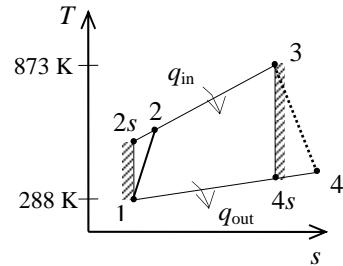

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the compression process,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (288 \text{ K})(12)^{0.4/1.4} = 585.8 \text{ K}$$

$$\begin{aligned} \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C} \\ &= 288 + \frac{585.8 - 288}{0.90} = 618.9 \text{ K} \end{aligned}$$

For the expansion process,

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (873 \text{ K}) \left(\frac{1}{12} \right)^{0.4/1.4} = 429.2 \text{ K}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s}) \\ &= 873 - (0.90)(873 - 429.2) \\ &= 473.6 \text{ K} \end{aligned}$$

The isentropic and actual work of compressor and turbine are

$$W_{\text{Comp},s} = c_p(T_{2s} - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(585.8 - 288) \text{ K} = 299.3 \text{ kJ/kg}$$

$$W_{\text{Comp}} = c_p(T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(618.9 - 288) \text{ K} = 332.6 \text{ kJ/kg}$$

$$W_{\text{Turb},s} = c_p(T_3 - T_{4s}) = (1.005 \text{ kJ/kg}\cdot\text{K})(873 - 429.2) \text{ K} = 446.0 \text{ kJ/kg}$$

$$W_{\text{Turb}} = c_p(T_3 - T_4) = (1.005 \text{ kJ/kg}\cdot\text{K})(873 - 473.6) \text{ K} = 401.4 \text{ kJ/kg}$$

The back work ratio for 90% efficient compressor and isentropic turbine case is

$$r_{\text{bw}} = \frac{W_{\text{Comp}}}{W_{\text{Turb},s}} = \frac{332.6 \text{ kJ/kg}}{446.0 \text{ kJ/kg}} = \mathbf{0.7457}$$

The back work ratio for 90% efficient turbine and isentropic compressor case is

$$r_{\text{bw}} = \frac{W_{\text{Comp},s}}{W_{\text{Turb}}} = \frac{299.3 \text{ kJ/kg}}{401.4 \text{ kJ/kg}} = \mathbf{0.7456}$$

The two results are almost identical.

9-95 A gas turbine power plant that operates on the simple Brayton cycle with air as the working fluid has a specified pressure ratio. The required mass flow rate of air is to be determined for two cases.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are

$$c_p = 1.005 \text{ kJ/kg}\cdot\text{K} \text{ and } k = 1.4 \text{ (Table A-2).}$$

Analysis (a) Using the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) (12)^{0.4/1.4} = 610.2 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left(\frac{1}{12} \right)^{0.4/1.4} = 491.7 \text{ K}$$

$$w_{s,C,in} = h_{2s} - h_1 = c_p (T_{2s} - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(610.2 - 300)\text{K} = 311.75 \text{ kJ/kg}$$

$$w_{s,T,out} = h_3 - h_{4s} = c_p (T_3 - T_{4s}) = (1.005 \text{ kJ/kg}\cdot\text{K})(1000 - 491.7)\text{K} = 510.84 \text{ kJ/kg}$$

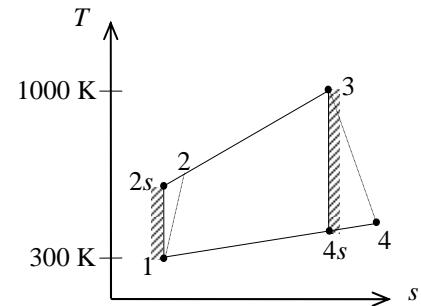

$$w_{s,net,out} = w_{s,T,out} - w_{s,C,in} = 510.84 - 311.75 = 199.1 \text{ kJ/kg}$$

$$\dot{m}_s = \frac{\dot{W}_{net,out}}{w_{s,net,out}} = \frac{70,000 \text{ kJ/s}}{199.1 \text{ kJ/kg}} = 352 \text{ kg/s}$$

(b) The net work output is determined to be

$$w_{a,net,out} = w_{a,T,out} - w_{a,C,in} = \eta_T w_{s,T,out} - w_{s,C,in} / \eta_C \\ = (0.85)(510.84) - 311.75 / 0.85 = 67.5 \text{ kJ/kg}$$

$$\dot{m}_a = \frac{\dot{W}_{net,out}}{w_{a,net,out}} = \frac{70,000 \text{ kJ/s}}{67.5 \text{ kJ/kg}} = 1037 \text{ kg/s}$$

9-96 An actual gas-turbine power plant operates at specified conditions. The fraction of the turbine work output used to drive the compressor and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (a) Using the isentropic relations,

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$T_2 = 580 \text{ K} \longrightarrow h_2 = 586.04 \text{ kJ/kg}$$

$$r_p = \frac{P_2}{P_1} = \frac{700}{100} = 7$$

$$q_{\text{in}} = h_3 - h_2 \longrightarrow h_3 = 950 + 586.04 = 1536.04 \text{ kJ/kg}$$

$$\rightarrow P_{r_3} = 474.11$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{7}\right)(474.11) = 67.73 \longrightarrow h_{4s} = 905.83 \text{ kJ/kg}$$

$$w_{C,\text{in}} = h_2 - h_1 = 586.04 - 300.19 = 285.85 \text{ kJ/kg}$$

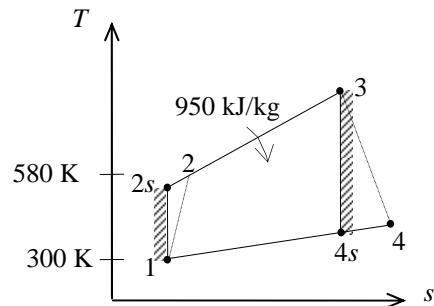

$$w_{T,\text{out}} = \eta_T (h_3 - h_{4s}) = (0.86)(1536.04 - 905.83) = 542.0 \text{ kJ/kg}$$

Thus,

$$r_{bw} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{285.85 \text{ kJ/kg}}{542.0 \text{ kJ/kg}} = 52.7\%$$

(b) $w_{\text{net,out}} = w_{T,\text{out}} - w_{C,\text{in}} = 542.0 - 285.85 = 256.15 \text{ kJ/kg}$

$$\eta_{th} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{256.15 \text{ kJ/kg}}{950 \text{ kJ/kg}} = 27.0\%$$

9-97 A gas-turbine power plant operates at specified conditions. The fraction of the turbine work output used to drive the compressor and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) Using constant specific heats,

$$r_p = \frac{P_2}{P_1} = \frac{700}{100} = 7$$

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = c_p(T_3 - T_2) \longrightarrow T_3 = T_2 + q_{\text{in}}/c_p \\ &= 580 \text{ K} + (950 \text{ kJ/kg})/(1.005 \text{ kJ/kg}\cdot\text{K}) \\ &= 1525.3 \text{ K} \end{aligned}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1525.3 \text{ K}) \left(\frac{1}{7} \right)^{0.4/1.4} = 874.8 \text{ K}$$

$$w_{C,\text{in}} = h_2 - h_1 = c_p(T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(580 - 300) \text{ K} = 281.4 \text{ kJ/kg}$$

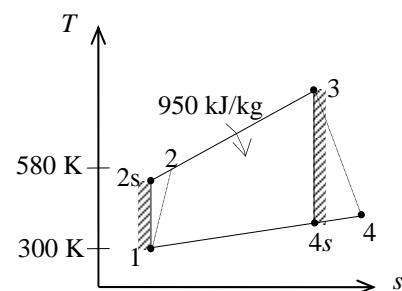

$$w_{T,\text{out}} = \eta_T(h_3 - h_{4s}) = \eta_T c_p(T_3 - T_{4s}) = (0.86)(1.005 \text{ kJ/kg}\cdot\text{K})(1525.3 - 874.8) \text{ K} = 562.2 \text{ kJ/kg}$$

Thus,

$$r_{bw} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{281.4 \text{ kJ/kg}}{562.2 \text{ kJ/kg}} = \mathbf{50.1\%}$$

$$(b) w_{\text{net,out}} = w_{T,\text{out}} - w_{C,\text{in}} = 562.2 - 281.4 = 280.8 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{280.8 \text{ kJ/kg}}{950 \text{ kJ/kg}} = \mathbf{29.6\%}$$

9-98 An aircraft engine operates as a simple ideal Brayton cycle with air as the working fluid. The pressure ratio and the rate of heat input are given. The net power and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the isentropic compression process,

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(10)^{0.4/1.4} = 527.1 \text{ K}$$

The heat addition is

$$q_{in} = \frac{\dot{Q}_{in}}{\dot{m}} = \frac{500 \text{ kW}}{1 \text{ kg/s}} = 500 \text{ kJ/kg}$$

Applying the first law to the heat addition process,

$$q_{in} = c_p(T_3 - T_2)$$

$$T_3 = T_2 + \frac{q_{in}}{c_p} = 527.1 \text{ K} + \frac{500 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 1025 \text{ K}$$

The temperature at the exit of the turbine is

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1025 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 530.9 \text{ K}$$

Applying the first law to the adiabatic turbine and the compressor produce

$$w_T = c_p(T_3 - T_4) = (1.005 \text{ kJ/kg}\cdot\text{K})(1025 - 530.9) \text{ K} = 496.6 \text{ kJ/kg}$$

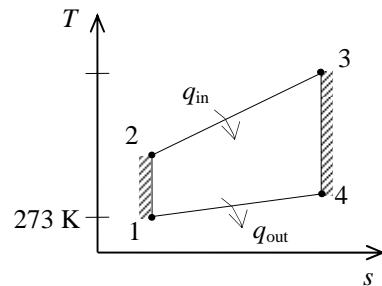

$$w_C = c_p(T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(527.1 - 273) \text{ K} = 255.4 \text{ kJ/kg}$$

The net power produced by the engine is then

$$\dot{W}_{net} = \dot{m}(w_T - w_C) = (1 \text{ kg/s})(496.6 - 255.4) \text{ kJ/kg} = \mathbf{241.2 \text{ kW}}$$

Finally the thermal efficiency is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{241.2 \text{ kW}}{500 \text{ kW}} = \mathbf{0.482}$$

9-99 An aircraft engine operates as a simple ideal Brayton cycle with air as the working fluid. The pressure ratio and the rate of heat input are given. The net power and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the isentropic compression process,

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(15)^{0.4/1.4} = 591.8 \text{ K}$$

The heat addition is

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{500 \text{ kW}}{1 \text{ kg/s}} = 500 \text{ kJ/kg}$$

Applying the first law to the heat addition process,

$$q_{\text{in}} = c_p(T_3 - T_2)$$

$$T_3 = T_2 + \frac{q_{\text{in}}}{c_p} = 591.8 \text{ K} + \frac{500 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 1089 \text{ K}$$

The temperature at the exit of the turbine is

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1089 \text{ K}) \left(\frac{1}{15} \right)^{0.4/1.4} = 502.3 \text{ K}$$

Applying the first law to the adiabatic turbine and the compressor produce

$$w_T = c_p(T_3 - T_4) = (1.005 \text{ kJ/kg}\cdot\text{K})(1089 - 502.3) \text{ K} = 589.6 \text{ kJ/kg}$$

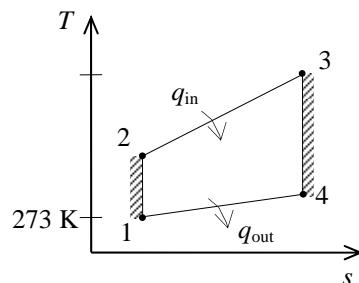

$$w_C = c_p(T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(591.8 - 273) \text{ K} = 320.4 \text{ kJ/kg}$$

The net power produced by the engine is then

$$\dot{W}_{\text{net}} = \dot{m}(w_T - w_C) = (1 \text{ kg/s})(589.6 - 320.4) \text{ kJ/kg} = \mathbf{269.2 \text{ kW}}$$

Finally the thermal efficiency is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{269.2 \text{ kW}}{500 \text{ kW}} = \mathbf{0.538}$$

9-100 A gas-turbine plant operates on the simple Brayton cycle. The net power output, the back work ratio, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) For this problem, we use the properties from EES software.

Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Compression

$$T_1 = 40^\circ\text{C} \longrightarrow h_1 = 313.6 \text{ kJ/kg}$$

$$\begin{aligned} T_1 = 40^\circ\text{C} \\ P_1 = 100 \text{ kPa} \end{aligned} \left. \begin{aligned} s_1 &= 5.749 \text{ kJ/kg}\cdot\text{K} \\ h_{2s} &= 736.7 \text{ kJ/kg} \end{aligned} \right\}$$

$$\begin{aligned} P_2 = 2000 \text{ kPa} \\ s_2 = s_1 = 5.749 \text{ kJ/kg}\cdot\text{K} \end{aligned} \left. \begin{aligned} h_{2s} &= 736.7 \text{ kJ/kg} \\ h_2 &= 811.4 \text{ kJ/kg} \end{aligned} \right\}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.85 = \frac{736.7 - 313.6}{h_2 - 313.6} \longrightarrow h_2 = 811.4 \text{ kJ/kg}$$

Process 3-4: Expansion

$$T_4 = 650^\circ\text{C} \longrightarrow h_4 = 959.2 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.88 = \frac{h_3 - 959.2}{h_3 - h_{4s}}$$

We cannot find the enthalpy at state 3 directly. However, using the following lines in EES together with the isentropic efficiency relation, we find $h_3 = 1873 \text{ kJ/kg}$, $T_3 = 1421^\circ\text{C}$, $s_3 = 6.736 \text{ kJ/kg}\cdot\text{K}$. The solution by hand would require a trial-error approach.

`h_3=enthalpy(Air, T=T_3)`

`s_3=entropy(Air, T=T_3, P=P_2)`

`h_4s=enthalpy(Air, P=P_1, s=s_3)`

The mass flow rate is determined from

$$\dot{m} = \frac{P_1 \dot{V}_1}{RT_1} = \frac{(100 \text{ kPa})(700/60 \text{ m}^3/\text{s})}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(40 + 273 \text{ K})} = 12.99 \text{ kg/s}$$

The net power output is

$$\dot{W}_{C,in} = \dot{m}(h_2 - h_1) = (12.99 \text{ kg/s})(811.4 - 313.6) \text{ kJ/kg} = 6464 \text{ kW}$$

$$\dot{W}_{T,out} = \dot{m}(h_3 - h_4) = (12.99 \text{ kg/s})(1873 - 959.2) \text{ kJ/kg} = 11,868 \text{ kW}$$

$$\dot{W}_{net} = \dot{W}_{T,out} - \dot{W}_{C,in} = 11,868 - 6464 = \mathbf{5404 \text{ kW}}$$

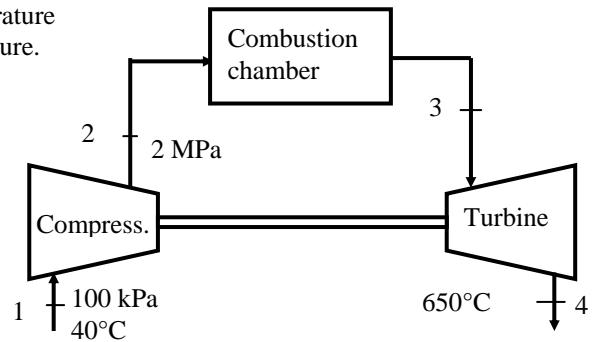

(b) The back work ratio is

$$r_{bw} = \frac{\dot{W}_{C,in}}{\dot{W}_{T,out}} = \frac{6464 \text{ kW}}{11,868 \text{ kW}} = \mathbf{0.545}$$

(c) The rate of heat input and the thermal efficiency are

$$\dot{Q}_{in} = \dot{m}(h_3 - h_2) = (12.99 \text{ kg/s})(1873 - 811.4) \text{ kJ/kg} = 13,788 \text{ kW}$$

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{5404 \text{ kW}}{13,788 \text{ kW}} = 0.392 = \mathbf{39.2\%}$$

9-101 A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The cycle is to be sketched on the $T-s$ cycle and the isentropic efficiency of the turbine and the cycle thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$.

Analysis (b) For the compression process,

$$\begin{aligned}\dot{W}_{\text{Comp}} &= \dot{m}c_p(T_2 - T_1) \\ &= (200 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(330 - 30)\text{K} \\ &= 60,300 \text{ kW}\end{aligned}$$

For the turbine during the isentropic process,

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{100 \text{ kPa}}{800 \text{ kPa}} \right)^{0.4/1.4} = 772.9 \text{ K}$$

$$\dot{W}_{\text{Turb,s}} = \dot{m}c_p(T_3 - T_{4s}) = (200 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1400 - 772.9)\text{K} = 126,050 \text{ kW}$$

The actual power output from the turbine is

$$\begin{aligned}\dot{W}_{\text{net}} &= \dot{W}_{\text{Turb}} - \dot{W}_{\text{Comp}} \\ \dot{W}_{\text{Turb}} &= \dot{W}_{\text{net}} + \dot{W}_{\text{Turb}} = 60,000 + 60,300 = 120,300 \text{ kW}\end{aligned}$$

The isentropic efficiency of the turbine is then

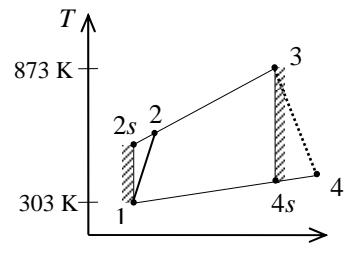

$$\eta_{\text{Turb}} = \frac{\dot{W}_{\text{Turb}}}{\dot{W}_{\text{Turb,s}}} = \frac{120,300 \text{ kW}}{126,050 \text{ kW}} = 0.954 = \mathbf{95.4\%}$$

(c) The rate of heat input is

$$\dot{Q}_{\text{in}} = \dot{m}c_p(T_3 - T_2) = (200 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})[(1400 - (330 + 273))\text{K}] = 160,200 \text{ kW}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{60,000 \text{ kW}}{160,200 \text{ kW}} = 0.375 = \mathbf{37.5\%}$$

9-102 A modified Brayton cycle with air as the working fluid operates at a specified pressure ratio. The T - s diagram is to be sketched and the temperature and pressure at the exit of the high-pressure turbine and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$.

Analysis (b) For the compression process,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (273 \text{ K})(8)^{0.4/1.4} = 494.5 \text{ K}$$

The power input to the compressor is equal to the power output from the high-pressure turbine. Then,

$$\begin{aligned} \dot{W}_{\text{Comp,in}} &= \dot{W}_{\text{HP Turb,out}} \\ \dot{m}c_p(T_2 - T_1) &= \dot{m}c_p(T_3 - T_4) \\ T_2 - T_1 &= T_3 - T_4 \\ T_4 &= T_3 + T_1 - T_2 = 1500 + 273 - 494.5 = \mathbf{1278.5 \text{ K}} \end{aligned}$$

The pressure at this state is

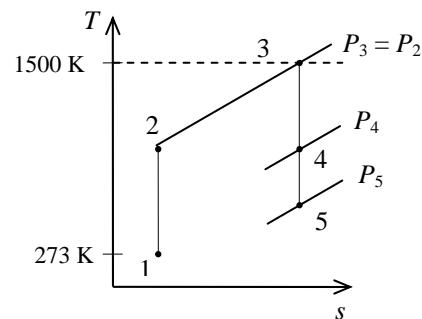

$$\frac{P_4}{P_3} = \left(\frac{T_4}{T_3} \right)^{k/(k-1)} \longrightarrow P_4 = rP_1 \left(\frac{T_4}{T_3} \right)^{k/(k-1)} = 8(100 \text{ kPa}) \left(\frac{1278.5 \text{ K}}{1500 \text{ K}} \right)^{1.4/0.4} = \mathbf{457.3 \text{ kPa}}$$

(c) The temperature at state 5 is determined from

$$T_5 = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (1278.5 \text{ K}) \left(\frac{100 \text{ kPa}}{457.3 \text{ kPa}} \right)^{0.4/1.4} = 828.1 \text{ K}$$

The net power is that generated by the low-pressure turbine since the power output from the high-pressure turbine is equal to the power input to the compressor. Then,

$$\begin{aligned} \dot{W}_{\text{LP Turb}} &= \dot{m}c_p(T_4 - T_5) \\ \dot{m} &= \frac{\dot{W}_{\text{LP Turb}}}{c_p(T_4 - T_5)} = \frac{200,000 \text{ kW}}{(1.005 \text{ kJ/kg}\cdot\text{K})(1278.5 - 828.1) \text{ K}} = \mathbf{441.8 \text{ kg/s}} \end{aligned}$$

9-103 A simple Brayton cycle with air as the working fluid operates at a specified pressure ratio and between the specified temperature and pressure limits. The cycle is to be sketched on the $T-s$ cycle and the volume flow rate of the air into the compressor is to be determined. Also, the effect of compressor inlet temperature on the mass flow rate and the net power output are to be investigated.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$.

Analysis (b) For the compression process,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (273 \text{ K}) (7)^{0.4/1.4} = 476.0 \text{ K}$$

$$\eta_{\text{Comp}} = \frac{\dot{W}_{\text{Comp},s}}{\dot{W}_{\text{Comp}}} = \frac{\dot{m}c_p(T_{2s} - T_1)}{\dot{m}c_p(T_2 - T_1)} = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.80 = \frac{476.0 - 273}{T_2 - 273} \longrightarrow T_2 = 526.8 \text{ K}$$

For the expansion process,

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1500 \text{ K}) \left(\frac{1}{7} \right)^{0.4/1.4} = 860.3 \text{ K}$$

$$\eta_{\text{Turb}} = \frac{\dot{W}_{\text{Turb}}}{\dot{W}_{\text{Turb},s}} = \frac{\dot{m}c_p(T_3 - T_4)}{\dot{m}c_p(T_3 - T_{4s})} = \frac{T_3 - T_4}{T_3 - T_{4s}}$$

$$0.90 = \frac{1500 - T_4}{1500 - 860.3} \longrightarrow T_4 = 924.3 \text{ K}$$

Given the net power, the mass flow rate is determined from

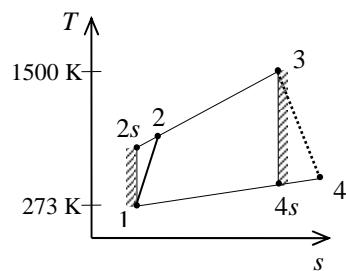

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{W}_{\text{Turb}} - \dot{W}_{\text{Comp}} = \dot{m}c_p(T_3 - T_4) - \dot{m}c_p(T_2 - T_1) \\ \dot{W}_{\text{net}} &= \dot{m}c_p[(T_3 - T_4) - (T_2 - T_1)] \\ \dot{m} &= \frac{\dot{W}_{\text{net}}}{c_p[(T_3 - T_4) - (T_2 - T_1)]} \\ &= \frac{150,000 \text{ kW}}{(1.005 \text{ kJ/kg}\cdot\text{K})[(1500 - 924.3) - (526.8 - 273)]} \\ &= 463.7 \text{ kg/s} \end{aligned}$$

The specific volume and the volume flow rate at the inlet of the compressor are

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(273 \text{ K})}{100 \text{ kPa}} = 0.7835 \text{ m}^3/\text{kg}$$

$$\dot{V}_1 = \dot{m}\nu_1 = (463.7 \text{ kg/s})(0.7835 \text{ m}^3/\text{kg}) = \mathbf{363.2 \text{ m}^3/\text{s}}$$

(c) For a fixed compressor inlet velocity and flow area, when the compressor inlet temperature increases, the specific volume increases since $\nu = \frac{RT}{P}$. When specific volume increases, the mass flow rate decreases since $\dot{m} = \frac{\dot{V}}{\nu}$. Note that volume flow rate is the same since inlet velocity and flow area are fixed ($\dot{V} = AV$). When mass flow rate decreases, the net power decreases since $\dot{W}_{\text{net}} = \dot{m}(w_{\text{Turb}} - w_{\text{Comp}})$. Therefore, when the inlet temperature increases, both mass flow rate and the net power decrease.

Brayton Cycle with Regeneration

9-104C Regeneration increases the thermal efficiency of a Brayton cycle by capturing some of the waste heat from the exhaust gases and preheating the air before it enters the combustion chamber.

9-105C Yes. At very high compression ratios, the gas temperature at the turbine exit may be lower than the temperature at the compressor exit. Therefore, if these two streams are brought into thermal contact in a regenerator, heat will flow to the exhaust gases instead of from the exhaust gases. As a result, the thermal efficiency will decrease.

9-106C The extent to which a regenerator approaches an ideal regenerator is called the effectiveness ε , and is defined as $\varepsilon = q_{\text{regen, act}} / q_{\text{regen, max}}$.

9-107C (b) turbine exit.

9-108C The steam injected increases the mass flow rate through the turbine and thus the power output. This, in turn, increases the thermal efficiency since $\eta = W / Q_{\text{in}}$ and W increases while Q_{in} remains constant. Steam can be obtained by utilizing the hot exhaust gases.

9-109 A Brayton cycle with regeneration produces 150 kW power. The rates of heat addition and rejection are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (293 \text{ K})(8)^{0.4/1.4} = 530.8 \text{ K}$$

$$T_5 = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left(\frac{1}{8} \right)^{0.4/1.4} = 592.3 \text{ K}$$

When the first law is applied to the heat exchanger, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 10 = 592.3 - 10 = 582.3 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - (T_3 - T_2) = 592.3 - (582.3 - 530.8) = 540.8 \text{ K}$$

Application of the first law to the turbine and compressor gives

$$\begin{aligned} w_{\text{net}} &= c_p (T_4 - T_5) - c_p (T_2 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 592.3) \text{ K} - (1.005 \text{ kJ/kg}\cdot\text{K})(530.8 - 293) \text{ K} \\ &= 244.1 \text{ kJ/kg} \end{aligned}$$

Then,

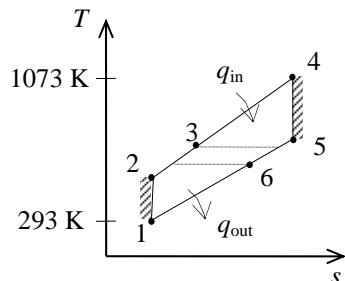

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150 \text{ kW}}{244.1 \text{ kJ/kg}} = 0.6145 \text{ kg/s}$$

Applying the first law to the combustion chamber produces

$$\dot{Q}_{\text{in}} = \dot{m} c_p (T_4 - T_3) = (0.6145 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 582.3) \text{ K} = \mathbf{303.0 \text{ kW}}$$

Similarly,

$$\dot{Q}_{\text{out}} = \dot{m} c_p (T_6 - T_1) = (0.6145 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(540.8 - 293) \text{ K} = \mathbf{153.0 \text{ kW}}$$

9-110 A Brayton cycle with regeneration produces 150 kW power. The rates of heat addition and rejection are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the compression and expansion processes we have

$$\begin{aligned} T_{2s} &= T_1 r_p^{(k-1)/k} = (293 \text{ K})(8)^{0.4/1.4} = 530.8 \text{ K} \\ \eta_C &= \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C} \\ &= 293 + \frac{530.8 - 293}{0.87} = 566.3 \text{ K} \\ T_{5s} &= T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left(\frac{1}{8} \right)^{0.4/1.4} = 592.3 \text{ K} \\ \eta_T &= \frac{c_p(T_4 - T_{5s})}{c_p(T_4 - T_5)} \longrightarrow T_5 = T_4 - \eta_T(T_4 - T_{5s}) \\ &= 1073 - (0.93)(1073 - 592.3) \\ &= 625.9 \text{ K} \end{aligned}$$

When the first law is applied to the heat exchanger, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 10 = 625.9 - 10 = 615.9 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - (T_3 - T_2) = 625.9 - (615.9 - 566.3) = 576.3 \text{ K}$$

Application of the first law to the turbine and compressor gives

$$\begin{aligned} w_{\text{net}} &= c_p(T_4 - T_5) - c_p(T_2 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 625.9) \text{ K} - (1.005 \text{ kJ/kg}\cdot\text{K})(566.3 - 293) \text{ K} \\ &= 174.7 \text{ kJ/kg} \end{aligned}$$

Then,

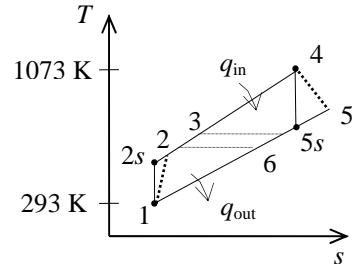

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150 \text{ kW}}{174.7 \text{ kJ/kg}} = 0.8586 \text{ kg/s}$$

Applying the first law to the combustion chamber produces

$$\dot{Q}_{\text{in}} = \dot{m} c_p (T_4 - T_3) = (0.8586 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 615.9) \text{ K} = \mathbf{394.4 \text{ kW}}$$

Similarly,

$$\dot{Q}_{\text{out}} = \dot{m} c_p (T_6 - T_1) = (0.8586 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(576.3 - 293) \text{ K} = \mathbf{244.5 \text{ kW}}$$

9-111 A Brayton cycle with regeneration is considered. The thermal efficiencies of the cycle for parallel-flow and counter-flow arrangements of the regenerator are to be compared.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (293 \text{ K})(7)^{0.4/1.4} = 510.9 \text{ K}$$

$$T_5 = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1000 \text{ K}) \left(\frac{1}{7} \right)^{0.4/1.4} = 573.5 \text{ K}$$

When the first law is applied to the heat exchanger as originally arranged, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 6 = 573.5 - 6 = 567.5 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - T_3 + T_2 = 573.5 - 567.5 + 510.9 = 516.9 \text{ K}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{516.9 - 293}{1000 - 567.5} = \mathbf{0.482}$$

For the rearranged version of this cycle,

$$T_3 = T_6 - 6$$

An energy balance on the heat exchanger gives

$$T_3 - T_2 = T_5 - T_6$$

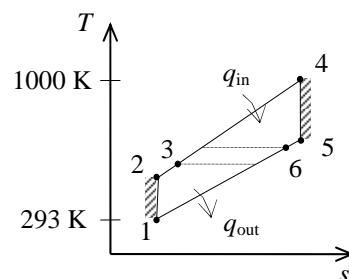

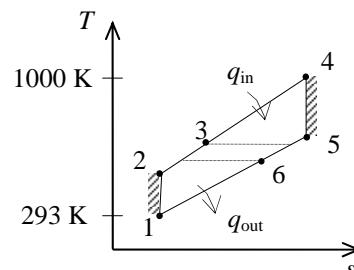

The solution of these two equations is

$$T_3 = 539.2 \text{ K}$$

$$T_6 = 545.2 \text{ K}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{545.2 - 293}{1000 - 539.2} = \mathbf{0.453}$$

9-112E An ideal Brayton cycle with regeneration has a pressure ratio of 11. The thermal efficiency of the cycle is to be determined with and without regenerator cases.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (560 \text{ R})(11)^{0.4/1.4} = 1111 \text{ R}$$

$$T_5 = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (2400 \text{ R}) \left(\frac{1}{11} \right)^{0.4/1.4} = 1210 \text{ R}$$

The regenerator is ideal (i.e., the effectiveness is 100%) and thus,

$$T_3 = T_5 = 1210 \text{ R}$$

$$T_6 = T_2 = 1111 \text{ R}$$

The thermal efficiency of the cycle is then

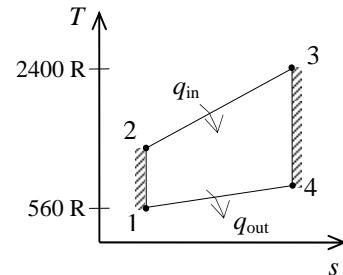

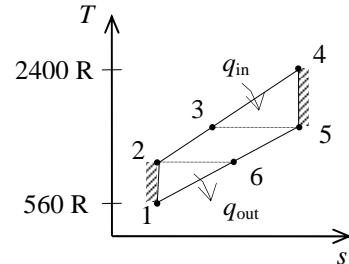

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{1111 - 560}{2400 - 1210} = 0.537 = \mathbf{53.7\%}$$

The solution without a regenerator is as follows:

$$T_2 = T_1 r_p^{(k-1)/k} = (560 \text{ R})(11)^{0.4/1.4} = 1111 \text{ R}$$

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (2400 \text{ R}) \left(\frac{1}{11} \right)^{0.4/1.4} = 1210 \text{ R}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_4 - T_1}{T_3 - T_2} = 1 - \frac{1210 - 560}{2400 - 1111} = 0.496 = \mathbf{49.6\%}$$

9-113E A car is powered by a gas turbine with a pressure ratio of 4. The thermal efficiency of the car and the mass flow rate of air for a net power output of 95 hp are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air is an ideal gas with variable specific heats. **3** The ambient air is 540 R and 14.5 psia. **4** The effectiveness of the regenerator is 0.9, and the isentropic efficiencies for both the compressor and the turbine are 80%. **5** The combustion gases can be treated as air.

Properties The properties of air at the compressor and turbine inlet temperatures can be obtained from Table A-17E.

Analysis The gas turbine cycle with regeneration can be analyzed as follows:

$$T_1 = 540 \text{ R} \longrightarrow h_1 = 129.06 \text{ Btu/lbm}$$

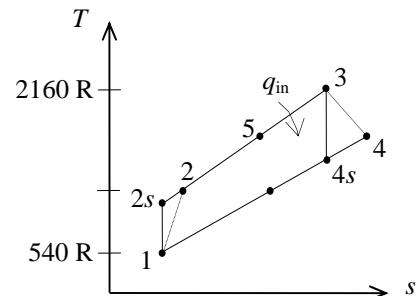

$$P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (4)(1.386) = 5.544 \longrightarrow h_{2s} = 192.0 \text{ Btu/lbm}$$

$$T_3 = 2160 \text{ R} \longrightarrow h_3 = 549.35 \text{ Btu/lbm}$$

$$P_{r_3} = 230.12$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{4}\right)(230.12) = 57.53 \longrightarrow h_{4s} = 372.2 \text{ Btu/lbm}$$

and

$$\eta_{\text{comp}} = \frac{h_{2s} - h_1}{h_2 - h_1} \rightarrow 0.80 = \frac{192.0 - 129.06}{h_2 - 129.06} \rightarrow h_2 = 207.74 \text{ Btu/lbm}$$

$$\eta_{\text{turb}} = \frac{h_3 - h_4}{h_3 - h_{4s}} \rightarrow 0.80 = \frac{549.35 - h_4}{549.35 - 372.2} \rightarrow h_4 = 407.63 \text{ Btu/lbm}$$

Then the thermal efficiency of the gas turbine cycle becomes

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = 0.9(407.63 - 207.74) = 179.9 \text{ Btu/lbm}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (549.35 - 207.74) - 179.9 = 161.7 \text{ Btu/lbm}$$

$$w_{\text{net,out}} = w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) = (549.35 - 407.63) - (207.74 - 129.06) = 63.0 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{63.0 \text{ Btu/lbm}}{161.7 \text{ Btu/lbm}} = 0.39 = \mathbf{39\%}$$

Finally, the mass flow rate of air through the turbine becomes

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{95 \text{ hp}}{63.0 \text{ Btu/lbm}} \left(\frac{0.7068 \text{ Btu/s}}{1 \text{ hp}} \right) = \mathbf{1.07 \text{ lbm/s}}$$

9-114 The thermal efficiency and power output of an actual gas turbine are given. The isentropic efficiency of the turbine and of the compressor, and the thermal efficiency of the gas turbine modified with a regenerator are to be determined.

Assumptions 1 Air is an ideal gas with variable specific heats. 2 Kinetic and potential energy changes are negligible. 3 The mass flow rates of air and of the combustion gases are the same, and the properties of combustion gases are the same as those of air.

Properties The properties of air are given in Table A-17.

Analysis The properties at various states are

$$T_1 = 30^\circ\text{C} = 303 \text{ K} \longrightarrow h_1 = 303.21 \text{ kJ/kg}$$

$$P_{r_1} = 1.4356$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (14.7)(1.4356) = 21.10 \longrightarrow h_{2s} = 653.25 \text{ kJ/kg}$$

$$T_3 = 1288^\circ\text{C} = 1561 \text{ K} \longrightarrow h_3 = 1710.0 \text{ kJ/kg}$$

$$P_{r_3} = 712.5$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{14.7} \right)(712.5) = 48.47 \longrightarrow h_{4s} = 825.23 \text{ kJ/kg}$$

The net work output and the heat input per unit mass are

$$w_{\text{net}} = \frac{\dot{W}_{\text{net}}}{\dot{m}} = \frac{159,000 \text{ kW}}{1,536,000 \text{ kg/h}} \left(\frac{3600 \text{ s}}{1 \text{ h}} \right) = 372.66 \text{ kJ/kg}$$

$$q_{\text{in}} = \frac{w_{\text{net}}}{\eta_{\text{th}}} = \frac{372.66 \text{ kJ/kg}}{0.359} = 1038.0 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 \rightarrow h_2 = h_3 - q_{\text{in}} = 1710 - 1038 = 672.0 \text{ kJ/kg}$$

$$q_{\text{out}} = q_{\text{in}} - w_{\text{net}} = 1038.0 - 372.66 = 665.34 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 \rightarrow h_4 = q_{\text{out}} + h_1 = 665.34 + 303.21 = 968.55 \text{ kJ/kg} \rightarrow T_4 = 931.7 \text{ K} = 658.7^\circ\text{C}$$

Then the compressor and turbine efficiencies become

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{1710 - 968.55}{1710 - 825.23} = 0.838 = 83.8\%$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{653.25 - 303.21}{672 - 303.21} = 0.949 = 94.9\%$$

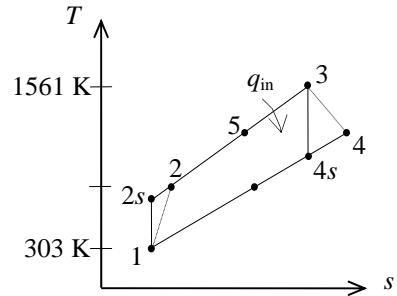

When a regenerator is added, the new heat input and the thermal efficiency become

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.65)(968.55 - 672.0) = 192.8 \text{ kJ/kg}$$

$$q_{\text{in,new}} = q_{\text{in}} - q_{\text{regen}} = 1038 - 192.8 = 845.2 \text{ kJ/kg}$$

$$\eta_{\text{th,new}} = \frac{w_{\text{net}}}{q_{\text{in,new}}} = \frac{372.66 \text{ kJ/kg}}{845.2 \text{ kJ/kg}} = 0.441 = 44.1\%$$

Discussion Note a 65% efficient regenerator would increase the thermal efficiency of this gas turbine from 35.9% to 44.1%.

9-115 Problem 9-114 is reconsidered. A solution that allows different isentropic efficiencies for the compressor and turbine is to be developed and the effect of the isentropic efficiencies on net work done and the heat supplied to the cycle is to be studied. Also, the *T-s* diagram for the cycle is to be plotted.

Analysis Using EES, the problem is solved as follows:

9-116 A Brayton cycle with regeneration using air as the working fluid is considered. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The properties of air at various states are

$$T_1 = 310 \text{ K} \longrightarrow \frac{h_1}{P_{r_1}} = 1.5546$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (7)(1.5546) = 10.88 \longrightarrow h_{2s} = 541.26 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + (h_{2s} - h_1)/\eta_C = 310.24 + (541.26 - 310.24)/(0.75) = 618.26 \text{ kJ/kg}$$

$$T_3 = 1150 \text{ K} \longrightarrow \frac{h_3}{P_{r_3}} = 200.15$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{7}\right)(200.15) = 28.59 \longrightarrow h_{4s} = 711.80 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1219.25 - (0.82)(1219.25 - 711.80) = 803.14 \text{ kJ/kg}$$

Thus,

$$T_4 = \mathbf{782.8 \text{ K}}$$

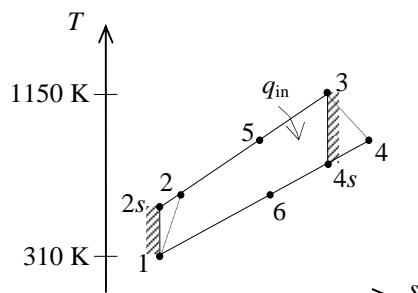

$$(b) \quad w_{\text{net}} = w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) \\ = (1219.25 - 803.14) - (618.26 - 310.24) \\ = \mathbf{108.09 \text{ kJ/kg}}$$

$$(c) \quad \varepsilon = \frac{h_5 - h_2}{h_4 - h_2} \longrightarrow h_5 = h_2 + \varepsilon(h_4 - h_2) \\ = 618.26 + (0.65)(803.14 - 618.26) \\ = 738.43 \text{ kJ/kg}$$

Then,

$$q_{\text{in}} = h_3 - h_5 = 1219.25 - 738.43 = 480.82 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{108.09 \text{ kJ/kg}}{480.82 \text{ kJ/kg}} = \mathbf{22.5\%}$$

9-117 A stationary gas-turbine power plant operating on an ideal regenerative Brayton cycle with air as the working fluid is considered. The power delivered by this plant is to be determined for two cases.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas. **3** Kinetic and potential energy changes are negligible.

Properties When assuming constant specific heats, the properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg.K}$ and $k = 1.4$ (Table A-2a). When assuming variable specific heats, the properties of air are obtained from Table A-17.

Analysis (a) Assuming constant specific heats,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (290 \text{ K}) (8)^{0.4/1.4} = 525.3 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1100 \text{ K}) \left(\frac{1}{8} \right)^{0.4/1.4} = 607.2 \text{ K}$$

$$\varepsilon = 100\% \longrightarrow T_5 = T_4 = 607.2 \text{ K} \text{ and } T_6 = T_2 = 525.3 \text{ K}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_p(T_6 - T_1)}{c_p(T_3 - T_5)} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{525.3 - 290}{1100 - 607.2} = 0.5225$$

$$\dot{W}_{\text{net}} = \eta_T \dot{Q}_{\text{in}} = (0.5225)(75,000 \text{ kW}) = \mathbf{39,188 \text{ kW}}$$

(b) Assuming variable specific heats,

$$T_1 = 290 \text{ K} \longrightarrow \begin{aligned} h_1 &= 290.16 \text{ kJ/kg} \\ P_{r_1} &= 1.2311 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.2311) = 9.8488 \longrightarrow h_2 = 526.12 \text{ kJ/kg}$$

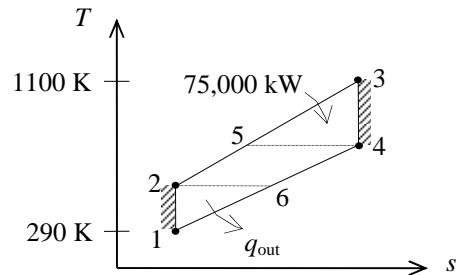

$$T_3 = 1100 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1161.07 \text{ kJ/kg} \\ P_{r_3} &= 167.1 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{8} \right)(167.1) = 20.89 \longrightarrow h_4 = 651.37 \text{ kJ/kg}$$

$$\varepsilon = 100\% \longrightarrow h_5 = h_4 = 651.37 \text{ kJ/kg} \text{ and } h_6 = h_2 = 526.12 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{h_6 - h_1}{h_3 - h_5} = 1 - \frac{526.12 - 290.16}{1161.07 - 651.37} = 0.5371$$

$$\dot{W}_{\text{net}} = \eta_T \dot{Q}_{\text{in}} = (0.5371)(75,000 \text{ kW}) = \mathbf{40,283 \text{ kW}}$$

9-118 A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The properties at various states are

$$r_p = P_2 / P_1 = 900 / 100 = 9$$

$$T_1 = 310 \text{ K} \longrightarrow h_1 = 310.24 \text{ kJ/kg}$$

$$T_2 = 650 \text{ K} \longrightarrow h_2 = 659.84 \text{ kJ/kg}$$

$$T_3 = 1400 \text{ K} \longrightarrow h_3 = 1515.42 \text{ kJ/kg}$$

$$P_{r_3} = 450.5$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{9}\right)(450.5) = 50.06 \longrightarrow h_{4s} = 832.44 \text{ kJ/kg}$$

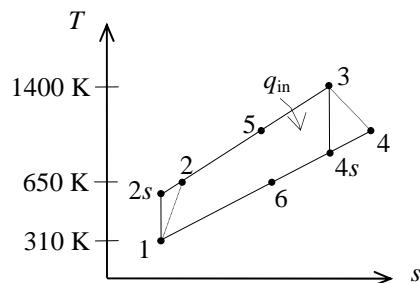

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1515.42 - (0.90)(1515.42 - 832.44) \\ &= 900.74 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.80)(900.74 - 659.84) = \mathbf{192.7 \text{ kJ/kg}}$$

$$(b) \quad w_{\text{net}} = w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) \\ = (1515.42 - 900.74) - (659.84 - 310.24) = 265.08 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (1515.42 - 659.84) - 192.7 = 662.88 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{265.08 \text{ kJ/kg}}{662.88 \text{ kJ/kg}} = 0.400 = \mathbf{40.0\%}$$

9-119 A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are

$$c_p = 1.005 \text{ kJ/kg}\cdot\text{K} \text{ and } k = 1.4 \text{ (Table A-2a).}$$

Analysis (a) Using the isentropic relations and turbine efficiency,

$$r_p = P_2 / P_1 = 900 / 100 = 9$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{1}{9} \right)^{0.4/1.4} = 747.3 \text{ K}$$

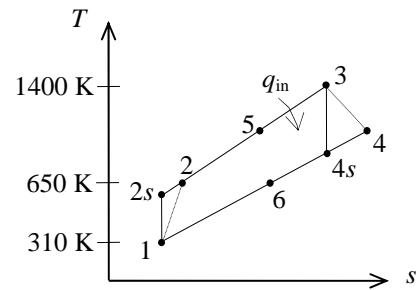

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \rightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s}) \\ = 1400 - (0.90)(1400 - 747.3) \\ = 812.6 \text{ K}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = \varepsilon c_p(T_4 - T_2) = (0.80)(1.005 \text{ kJ/kg}\cdot\text{K})(812.6 - 650) \text{ K} = \mathbf{130.7 \text{ kJ/kg}}$$

$$(b) w_{\text{net}} = w_{\text{T,out}} - w_{\text{C,in}} = c_p(T_3 - T_4) - c_p(T_2 - T_1) \\ = (1.005 \text{ kJ/kg}\cdot\text{K})[(1400 - 812.6) - (650 - 310)] \text{ K} = 248.7 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = c_p(T_3 - T_2) - q_{\text{regen}} \\ = (1.005 \text{ kJ/kg}\cdot\text{K})(1400 - 650) \text{ K} - 130.7 = 623.1 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{248.7 \text{ kJ/kg}}{623.1 \text{ kJ/kg}} = 0.399 = \mathbf{39.9\%}$$

9-120 A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The properties at various states are

$$r_p = P_2 / P_1 = 900 / 100 = 9$$

$$T_1 = 310 \text{ K} \longrightarrow h_1 = 310.24 \text{ kJ/kg}$$

$$T_2 = 650 \text{ K} \longrightarrow h_2 = 659.84 \text{ kJ/kg}$$

$$T_3 = 1400 \text{ K} \longrightarrow h_3 = 1515.42 \text{ kJ/kg}$$

$$P_{r_3} = 450.5$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{9} \right) (450.5) = 50.06 \longrightarrow h_{4s} = 832.44 \text{ kJ/kg}$$

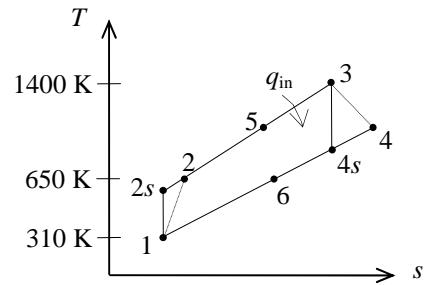

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) \\ &= 1515.42 - (0.90)(1515.42 - 832.44) \\ &= 900.74 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.70)(900.74 - 659.84) = \mathbf{168.6 \text{ kJ/kg}}$$

$$(b) \quad w_{\text{net}} = w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) \\ = (1515.42 - 900.74) - (659.84 - 310.24) = 265.08 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (1515.42 - 659.84) - 168.6 = 687.18 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{265.08 \text{ kJ/kg}}{687.18 \text{ kJ/kg}} = 0.386 = \mathbf{38.6\%}$$

9-121 An expression for the thermal efficiency of an ideal Brayton cycle with an ideal regenerator is to be developed.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

Analysis The expressions for the isentropic compression and expansion processes are

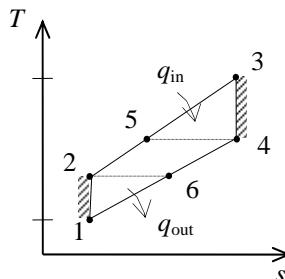

$$T_2 = T_1 r_p^{(k-1)/k}$$

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

For an ideal regenerator,

$$T_5 = T_4$$

$$T_6 = T_2$$

The thermal efficiency of the cycle is

$$\begin{aligned} \eta_{th} &= 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{T_1}{T_3} \frac{(T_6/T_1) - 1}{1 - (T_5/T_3)} \\ &= 1 - \frac{T_1}{T_3} \frac{(T_2/T_1) - 1}{1 - (T_4/T_3)} \\ &= 1 - \frac{T_1}{T_3} \frac{r_p^{(k-1)/k} - 1}{1 - r_p^{-(k-1)/k}} \\ &= 1 - \frac{T_1}{T_3} r_p^{(k-1)/k} \end{aligned}$$

Brayton Cycle with Intercooling, Reheating, and Regeneration

9-122C As the number of compression and expansion stages are increased and regeneration is employed, the ideal Brayton cycle will approach the Ericsson cycle.

9-123C Because the steady-flow work is proportional to the specific volume of the gas. Intercooling decreases the average specific volume of the gas during compression, and thus the compressor work. Reheating increases the average specific volume of the gas, and thus the turbine work output.

9-124C (a) decrease, (b) decrease, and (c) decrease.

9-125C (a) increase, (b) decrease, and (c) decrease.

9-126C (a) increase, (b) decrease, (c) decrease, and (d) increase.

9-127C (a) increase, (b) decrease, (c) increase, and (d) decrease.

9-128C (c) The Carnot (or Ericsson) cycle efficiency.

9-129 An ideal gas-turbine cycle with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency of the cycle are to be determined for the cases of with and without a regenerator.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine since this is an ideal cycle. Then,

$$T_1 = 300 \text{ K} \longrightarrow \begin{array}{l} h_1 = 300.19 \text{ kJ/kg} \\ P_{r_1} = 1.386 \end{array}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_2 = h_4 = 411.26 \text{ kJ/kg}$$

$$T_5 = 1200 \text{ K} \longrightarrow \begin{array}{l} h_5 = h_7 = 1277.79 \text{ kJ/kg} \\ P_{r_5} = 238 \end{array}$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_6 = h_8 = 946.36 \text{ kJ/kg}$$

$$w_{C,in} = 2(h_2 - h_1) = 2(411.26 - 300.19) = 222.14 \text{ kJ/kg}$$

$$w_{T,out} = 2(h_5 - h_6) = 2(1277.79 - 946.36) = 662.86 \text{ kJ/kg}$$

Thus,

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{222.14 \text{ kJ/kg}}{662.86 \text{ kJ/kg}} = 33.5\%$$

$$q_{in} = (h_5 - h_4) + (h_7 - h_6) = (1277.79 - 411.26) + (1277.79 - 946.36) = 1197.96 \text{ kJ/kg}$$

$$w_{net} = w_{T,out} - w_{C,in} = 662.86 - 222.14 = 440.72 \text{ kJ/kg}$$

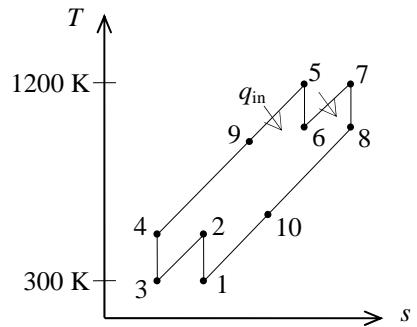

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{440.72 \text{ kJ/kg}}{1197.96 \text{ kJ/kg}} = 36.8\%$$

(b) When a regenerator is used, r_{bw} remains the same. The thermal efficiency in this case becomes

$$q_{regen} = \varepsilon(h_8 - h_4) = (0.75)(946.36 - 411.26) = 401.33 \text{ kJ/kg}$$

$$q_{in} = q_{in,old} - q_{regen} = 1197.96 - 401.33 = 796.63 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{440.72 \text{ kJ/kg}}{796.63 \text{ kJ/kg}} = 55.3\%$$

9-130 A gas-turbine cycle with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency of the cycle are to be determined for the cases of with and without a regenerator.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine. Then,

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_{2s} = h_{4s} = 411.26 \text{ kJ/kg}$$

$$\begin{aligned} \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_4 = h_1 + (h_{2s} - h_1)/\eta_C \\ &= 300.19 + (411.26 - 300.19)/(0.84) \\ &= 432.42 \text{ kJ/kg} \end{aligned}$$

$$T_5 = 1200 \text{ K} \longrightarrow h_5 = h_7 = 1277.79 \text{ kJ/kg}$$

$$P_{r_5} = 238$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_{6s} = h_{8s} = 946.36 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_8 = h_5 - \eta_T(h_5 - h_{6s}) \\ &= 1277.79 - (0.88)(1277.79 - 946.36) \\ &= 986.13 \text{ kJ/kg} \end{aligned}$$

$$w_{C,in} = 2(h_2 - h_1) = 2(432.42 - 300.19) = 264.46 \text{ kJ/kg}$$

$$w_{T,out} = 2(h_5 - h_6) = 2(1277.79 - 986.13) = 583.32 \text{ kJ/kg}$$

Thus,

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{264.46 \text{ kJ/kg}}{583.32 \text{ kJ/kg}} = 0.453 = \mathbf{45.3\%}$$

$$q_{in} = (h_5 - h_4) + (h_7 - h_6) = (1277.79 - 432.42) + (1277.79 - 986.13) = 1137.03 \text{ kJ/kg}$$

$$w_{net} = w_{T,out} - w_{C,in} = 583.32 - 264.46 = 318.86 \text{ kJ/kg}$$

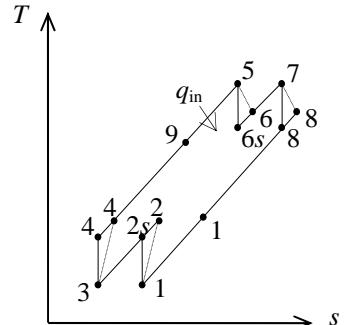

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{318.86 \text{ kJ/kg}}{1137.03 \text{ kJ/kg}} = 0.280 = \mathbf{28.0\%}$$

(b) When a regenerator is used, r_{bw} remains the same. The thermal efficiency in this case becomes

$$q_{regen} = \epsilon(h_8 - h_4) = (0.75)(986.13 - 432.42) = 415.28 \text{ kJ/kg}$$

$$q_{in} = q_{in,old} - q_{regen} = 1137.03 - 415.28 = 721.75 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{318.86 \text{ kJ/kg}}{721.75 \text{ kJ/kg}} = 0.442 = \mathbf{44.2\%}$$

9-131E An ideal regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The power produced and consumed by each compression and expansion stage, and the rate of heat rejected are to be determined.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis The pressure ratio for each stage is

$$r_p = \sqrt{12} = 3.464$$

According to the isentropic process expressions for an ideal gas,

$$T_2 = T_4 = T_1 r_p^{(k-1)/k} = (520 \text{ R})(3.464)^{0.4/1.4} = 741.6 \text{ R}$$

Since this is an ideal cycle,

$$T_5 = T_7 = T_9 = T_4 + 50 = 741.6 + 50 = 791.6 \text{ R}$$

For the isentropic expansion processes,

$$T_6 = T_8 = T_7 r_p^{(k-1)/k} = (791.6 \text{ R})(3.464)^{0.4/1.4} = 1129 \text{ R}$$

The heat input is

$$q_{\text{in}} = 2c_p(T_6 - T_5) = 2(0.24 \text{ Btu/lbm}\cdot\text{R})(1129 - 791.6) \text{ R} = 162.0 \text{ Btu/lbm}$$

The mass flow rate is then

$$\dot{m} = \frac{\dot{Q}_{\text{in}}}{q_{\text{in}}} = \frac{500 \text{ Btu/s}}{162.0 \text{ Btu/lbm}} = 3.086 \text{ lbm/s}$$

Application of the first law to the expansion process 6-7 gives

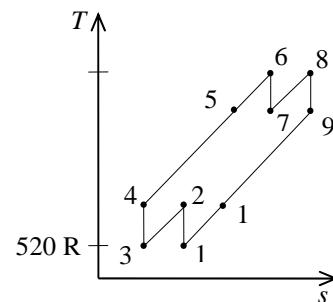

$$\begin{aligned} \dot{W}_{6-7,\text{out}} &= \dot{m}c_p(T_6 - T_7) \\ &= (3.086 \text{ lbm/s})(0.24 \text{ Btu/lbm}\cdot\text{R})(1129 - 791.6) \text{ R} \left(\frac{1 \text{ kW}}{0.94782 \text{ Btu/s}} \right) \\ &= \mathbf{263.6 \text{ kW}} \end{aligned}$$

The same amount of power is produced in process 8-9. When the first law is adapted to the compression process 1-2 it becomes

$$\begin{aligned} \dot{W}_{12,\text{in}} &= \dot{m}c_p(T_2 - T_1) \\ &= (3.086 \text{ lbm/s})(0.24 \text{ Btu/lbm}\cdot\text{R})(741.6 - 520) \text{ R} \left(\frac{1 \text{ kW}}{0.94782 \text{ Btu/s}} \right) \\ &= \mathbf{173.2 \text{ kW}} \end{aligned}$$

Compression process 3-4 uses the same amount of power. The rate of heat rejection from the cycle is

$$\begin{aligned} \dot{Q}_{\text{out}} &= 2\dot{m}c_p(T_2 - T_3) \\ &= 2(3.086 \text{ lbm/s})(0.24 \text{ Btu/lbm}\cdot\text{R})(741.6 - 520) \text{ R} \\ &= \mathbf{328.3 \text{ Btu/s}} \end{aligned}$$

9-132E An ideal regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The power produced and consumed by each compression and expansion stage, and the rate of heat rejected are to be determined.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

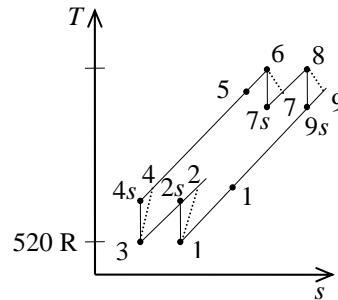

Properties The properties of air at room temperature are $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis The pressure ratio for each stage is

$$r_p = \sqrt{12} = 3.464$$

For the compression processes,

$$\begin{aligned} T_{2s} &= T_{4s} = T_1 r_p^{(k-1)/k} = (520 \text{ R})(3.464)^{0.4/1.4} = 741.6 \text{ R} \\ \eta_C &= \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_4 = T_1 + \frac{T_{2s} - T_1}{\eta_C} \\ &= 520 + \frac{741.6 - 520}{0.85} = 780.7 \text{ R} \end{aligned}$$

Since the regenerator is ideal,

$$T_5 = T_7 = T_9 = T_4 + 50 = 780.7 + 50 = 830.7 \text{ R}$$

For the expansion processes,

$$T_{6s} = T_{8s} = T_7 r_p^{(k-1)/k} = (830.7 \text{ R})(3.464)^{0.4/1.4} = 1185 \text{ R}$$

$$\eta_T = \frac{c_p(T_6 - T_7)}{c_p(T_{6s} - T_7)} \longrightarrow T_6 = T_8 = T_7 + \eta_T(T_{6s} - T_7) = 830.7 + (0.90)(1185 - 830.7) = 1150 \text{ R}$$

The heat input is

$$q_{in} = 2c_p(T_6 - T_5) = 2(0.24 \text{ Btu/lbm}\cdot\text{R})(1150 - 830.7) \text{ R} = 153.3 \text{ Btu/lbm}$$

The mass flow rate is then

$$\dot{m} = \frac{\dot{Q}_{in}}{q_{in}} = \frac{500 \text{ Btu/s}}{153.3 \text{ Btu/lbm}} = 3.262 \text{ lbm/s}$$

Application of the first law to the expansion process 6-7 gives

$$\begin{aligned} \dot{W}_{6-7,out} &= \dot{m}c_p(T_6 - T_7) \\ &= (3.262 \text{ lbm/s})(0.24 \text{ Btu/lbm}\cdot\text{R})(1150 - 830.7) \text{ R} \left(\frac{1 \text{ kW}}{0.94782 \text{ Btu/s}} \right) = \mathbf{263.7 \text{ kW}} \end{aligned}$$

The same amount of power is produced in process 8-9. When the first law is adapted to the compression process 1-2 it becomes

$$\begin{aligned} \dot{W}_{12,in} &= \dot{m}c_p(T_2 - T_1) \\ &= (3.262 \text{ lbm/s})(0.24 \text{ Btu/lbm}\cdot\text{R})(780.7 - 520) \text{ R} \left(\frac{1 \text{ kW}}{0.94782 \text{ Btu/s}} \right) = \mathbf{215.3 \text{ kW}} \end{aligned}$$

Compression process 3-4 uses the same amount of power. The rate of heat rejection from the cycle is

$$\begin{aligned} \dot{Q}_{out} &= 2\dot{m}c_p(T_2 - T_3) \\ &= 2(3.262 \text{ lbm/s})(0.24 \text{ Btu/lbm}\cdot\text{R})(780.7 - 520) \text{ R} = \mathbf{408.2 \text{ Btu/s}} \end{aligned}$$

9-133 A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The temperatures at various states are obtained as follows

$$T_2 = T_4 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

$$T_5 = T_4 + 20 = 430.9 + 20 = 450.9 \text{ K}$$

$$q_{\text{in}} = c_p(T_6 - T_5)$$

$$T_6 = T_5 + \frac{q_{\text{in}}}{c_p} = 450.9 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 749.4 \text{ K}$$

$$T_7 = T_6 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (749.4 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 504.3 \text{ K}$$

$$T_8 = T_7 + \frac{q_{\text{in}}}{c_p} = 504.3 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 802.8 \text{ K}$$

$$T_9 = T_8 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (802.8 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 540.2 \text{ K}$$

$$T_{10} = T_9 - 20 = 540.2 - 20 = 520.2 \text{ K}$$

The heat input is

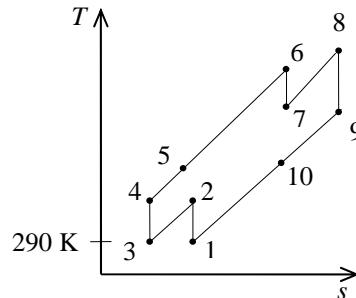

$$q_{\text{in}} = 300 + 300 = 600 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p(T_{10} - T_1) + c_p(T_2 - T_3) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(520.2 - 290 + 430.9 - 290) \text{ R} \\ &= 373.0 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{373.0}{600} = \mathbf{0.378}$$

9-134 A regenerative gas-turbine cycle with three stages of compression and three stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The temperatures at various states are obtained as follows

$$T_2 = T_4 = T_6 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

$$T_7 = T_6 + 20 = 430.9 + 20 = 450.9 \text{ K}$$

$$q_{\text{in}} = c_p(T_8 - T_7)$$

$$T_8 = T_7 + \frac{q_{\text{in}}}{c_p} = 450.9 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 749.4 \text{ K}$$

$$T_9 = T_8 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (749.4 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 504.3 \text{ K}$$

$$T_{10} = T_9 + \frac{q_{\text{in}}}{c_p} = 504.3 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 802.8 \text{ K}$$

$$T_{11} = T_{10} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (802.8 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 540.2 \text{ K}$$

$$T_{12} = T_{11} + \frac{q_{\text{in}}}{c_p} = 540.2 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 838.7 \text{ K}$$

$$T_{13} = T_{12} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (838.7 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 564.4 \text{ K}$$

$$T_{14} = T_{13} - 20 = 564.4 - 20 = 544.4 \text{ K}$$

The heat input is

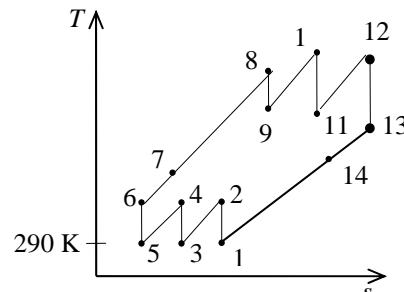

$$q_{\text{in}} = 300 + 300 + 300 = 900 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p(T_{14} - T_1) + c_p(T_2 - T_3) + c_p(T_4 - T_5) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(544.4 - 290 + 430.9 - 290 + 430.9 - 290) \text{ R} \\ &= 538.9 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{538.9}{900} = 0.401 = \mathbf{40.1\%}$$

9-135 A regenerative gas-turbine cycle with three stages of compression and three stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis Since all compressors share the same compression ratio and begin at the same temperature,

$$T_2 = T_4 = T_6 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

From the problem statement,

$$T_7 = T_{13} - 65$$

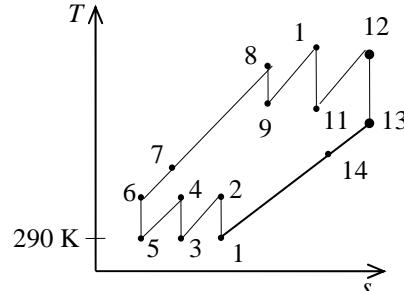

The relations for heat input and expansion processes are

$$q_{\text{in}} = c_p (T_8 - T_7) \longrightarrow T_8 = T_7 + \frac{q_{\text{in}}}{c_p}$$

$$T_9 = T_8 \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

$$T_{10} = T_9 + \frac{q_{\text{in}}}{c_p}, \quad T_{11} = T_{10} \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

$$T_{12} = T_{11} + \frac{q_{\text{in}}}{c_p}, \quad T_{13} = T_{12} \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

The simultaneous solution of above equations using EES software gives the following results

$$\begin{aligned} T_7 &= 520.7 \text{ K}, & T_8 &= 819.2 \text{ K}, & T_9 &= 551.3 \text{ K} \\ T_{10} &= 849.8 \text{ K}, & T_{11} &= 571.9 \text{ K}, & T_{12} &= 870.4 \text{ K}, & T_{13} &= 585.7 \text{ K} \end{aligned}$$

From an energy balance on the regenerator,

$$\begin{aligned} T_7 - T_6 &= T_{13} - T_{14} \\ (T_{13} - 65) - T_6 &= T_{13} - T_{14} \longrightarrow T_{14} = T_6 + 65 = 430.9 + 65 = 495.9 \text{ K} \end{aligned}$$

The heat input is

$$q_{\text{in}} = 300 + 300 + 300 = 900 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p (T_{14} - T_1) + c_p (T_2 - T_3) + c_p (T_4 - T_5) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(495.9 - 290 + 430.9 - 290 + 430.9 - 290) \text{ R} \\ &= 490.1 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{490.1}{900} = 0.455 = \mathbf{45.5\%}$$

Jet-Propulsion Cycles

9-136C The power developed from the thrust of the engine is called the propulsive power. It is equal to thrust times the aircraft velocity.

9-137C The ratio of the propulsive power developed and the rate of heat input is called the propulsive efficiency. It is determined by calculating these two quantities separately, and taking their ratio.

9-138C It reduces the exit velocity, and thus the thrust.

9-139E A turboprop engine operating on an ideal cycle is considered. The thrust force generated is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ (Table A-1E), $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis Working across the two isentropic processes of the cycle yields

$$T_2 = T_1 r_p^{(k-1)/k} = (450 \text{ R})(10)^{0.4/1.4} = 868.8 \text{ R}$$

$$T_5 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1400 \text{ R}) \left(\frac{1}{10} \right)^{0.4/1.4} = 725.1 \text{ R}$$

Since the work produced by expansion 3-4 equals that used by compression 1-2, an energy balance gives

$$T_4 = T_3 - (T_2 - T_1) = 1400 - (868.8 - 450) = 981.2 \text{ R}$$

The excess enthalpy generated by expansion 4-5 is used to increase the kinetic energy of the flow through the propeller,

$$\dot{m}_e c_p (T_4 - T_5) = \dot{m}_p \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

which when solved for the velocity at which the air leaves the propeller gives

$$\begin{aligned} V_{\text{exit}} &= \left[2 \frac{\dot{m}_e}{\dot{m}_p} c_p (T_4 - T_5) + V_{\text{inlet}}^2 \right]^{1/2} \\ &= \left[2 \frac{1}{20} (0.24 \text{ Btu/lbm}\cdot\text{R})(981.2 - 725.1) \text{R} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) + (600 \text{ ft/s})^2 \right]^{1/2} \\ &= 716.9 \text{ ft/s} \end{aligned}$$

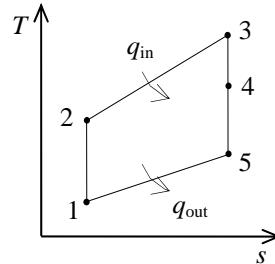

The mass flow rate through the propeller is

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia}\cdot\text{ft}^3)(450 \text{ R})}{8 \text{ psia}} = 20.84 \text{ ft}^3/\text{lbm}$$

$$\dot{m}_p = \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi(10 \text{ ft})^2}{4} \frac{600 \text{ ft/s}}{20.84 \text{ ft}^3/\text{lbm}} = 2261 \text{ lbm/s}$$

The thrust force generated by this propeller is then

$$F = \dot{m}_p (V_{\text{exit}} - V_{\text{inlet}}) = (2261 \text{ lbm/s})(716.9 - 600) \text{ ft/s} \left(\frac{1 \text{ lbf}}{32.174 \text{ lbm}\cdot\text{ft/s}^2} \right) = 8215 \text{ lbf}$$

9-140E A turboprop engine operating on an ideal cycle is considered. The thrust force generated is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.24 \text{ Btu/lbm} \cdot \text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis Working across the two isentropic processes of the cycle yields

$$T_2 = T_1 r_p^{(k-1)/k} = (450 \text{ R})(10)^{0.4/1.4} = 868.8 \text{ R}$$

$$T_5 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1400 \text{ R}) \left(\frac{1}{10} \right)^{0.4/1.4} = 725.1 \text{ R}$$

Since the work produced by expansion 3-4 equals that used by compression 1-2, an energy balance gives

$$T_4 = T_3 - (T_2 - T_1) = 1400 - (868.8 - 450) = 981.2 \text{ R}$$

The mass flow rate through the propeller is

$$\nu_1 = \frac{RT}{P} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3)(450 \text{ R})}{8 \text{ psia}} = 20.84 \text{ ft}^3/\text{lbm}$$

$$\dot{m}_p = \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi(8 \text{ ft})^2}{4} \frac{600 \text{ ft/s}}{20.84 \text{ ft}^3/\text{lbm}} = 1447 \text{ lbm/s}$$

According to the previous problem,

$$\dot{m}_e = \frac{\dot{m}_p}{20} = \frac{2261 \text{ lbm/s}}{20} = 113.1 \text{ lbm/s}$$

The excess enthalpy generated by expansion 4-5 is used to increase the kinetic energy of the flow through the propeller,

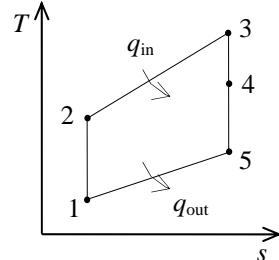

$$\dot{m}_e c_p (T_4 - T_5) = \dot{m}_p \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

which when solved for the velocity at which the air leaves the propeller gives

$$\begin{aligned} V_{\text{exit}} &= \left[2 \frac{\dot{m}_e}{\dot{m}_p} c_p (T_4 - T_5) + V_{\text{inlet}}^2 \right]^{1/2} \\ &= \left[2 \frac{113.1 \text{ lbm/s}}{1447 \text{ lbm/s}} (0.24 \text{ Btu/lbm} \cdot \text{R})(981.2 - 725.1) \text{ R} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) + (600 \text{ ft/s})^2 \right]^{1/2} \\ &= 775.0 \text{ ft/s} \end{aligned}$$

The thrust force generated by this propeller is then

$$F = \dot{m}_p (V_{\text{exit}} - V_{\text{inlet}}) = (1447 \text{ lbm/s})(775 - 600) \text{ ft/s} \left(\frac{1 \text{ lbf}}{32.174 \text{ lbm} \cdot \text{ft/s}^2} \right) = \mathbf{7870 \text{ lbf}}$$

9-141 A turbofan engine operating on an ideal cycle produces 50,000 N of thrust. The air temperature at the fan outlet needed to produce this thrust is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The total mass flow rate is

$$\nu_1 = \frac{RT}{P} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3)(253 \text{ K})}{50 \text{ kPa}} = 1.452 \text{ m}^3/\text{kg}$$

$$\dot{m} = \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi(2.5 \text{ m})^2}{4} \frac{200 \text{ m/s}}{1.452 \text{ m}^3/\text{kg}} = 676.1 \text{ kg/s}$$

Now,

$$\dot{m}_e = \frac{\dot{m}}{8} = \frac{676.1 \text{ kg/s}}{8} = 84.51 \text{ kg/s}$$

The mass flow rate through the fan is

$$\dot{m}_f = \dot{m} - \dot{m}_e = 676.1 - 84.51 = 591.6 \text{ kg/s}$$

In order to produce the specified thrust force, the velocity at the fan exit will be

$$F = \dot{m}_f (V_{\text{exit}} - V_{\text{inlet}})$$

$$V_{\text{exit}} = V_{\text{inlet}} + \frac{F}{\dot{m}_f} = (200 \text{ m/s}) + \frac{50,000 \text{ N}}{591.6 \text{ kg/s}} \left(\frac{1 \text{ kg} \cdot \text{m/s}^2}{1 \text{ N}} \right) = 284.5 \text{ m/s}$$

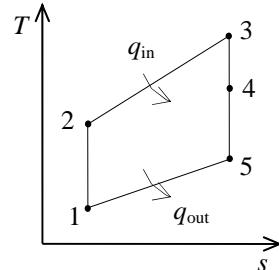

An energy balance on the stream passing through the fan gives

$$c_p (T_4 - T_5) = \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

$$T_5 = T_4 - \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2c_p}$$

$$= 253 \text{ K} - \frac{(284.5 \text{ m/s})^2 - (200 \text{ m/s})^2}{2(1.005 \text{ kJ/kg} \cdot \text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$= \mathbf{232.6 \text{ K}}$$

9-142 A pure jet engine operating on an ideal cycle is considered. The velocity at the nozzle exit and the thrust produced are to be determined.

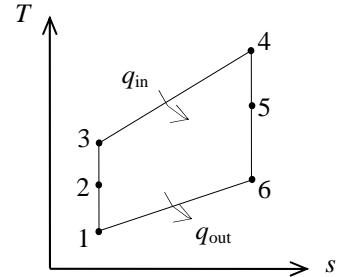

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$ and $k = 1.4$ (Table A-2a).

Analysis (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 240 \text{ m/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \approx 0$).

Diffuser:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{d0 (steady)}} \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_1 + V_1^2 / 2 &= h_2 + V_2^2 / 2 \xrightarrow{0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}} \\ 0 &= c_p(T_2 - T_1) - V_1^2 / 2 \\ T_2 &= T_1 + \frac{V_1^2}{2c_p} = 260 \text{ K} + \frac{(240 \text{ m/s})^2}{(2)(1.005 \text{ kJ/kg} \cdot \text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 288.7 \text{ K} \\ P_2 &= P_1 \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = (45 \text{ kPa}) \left(\frac{288.7 \text{ K}}{260 \text{ K}} \right)^{1.4/0.4} = 64.88 \text{ kPa}\end{aligned}$$

Compressor:

$$\begin{aligned}P_3 &= P_4 = (r_p)(P_2) = (13)(64.88 \text{ kPa}) = 843.5 \text{ kPa} \\ T_3 &= T_2 \left(\frac{P_3}{P_2} \right)^{(k-1)/k} = (288.7 \text{ K})(13)^{0.4/1.4} = 600.7 \text{ K}\end{aligned}$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \xrightarrow{} h_3 - h_2 = h_4 - h_5 \xrightarrow{} c_p(T_3 - T_2) = c_p(T_4 - T_5)$$

$$\text{or } T_5 = T_4 - T_3 + T_2 = 830 - 600.7 + 288.7 = 518.0 \text{ K}$$

Nozzle:

$$\begin{aligned}T_6 &= T_4 \left(\frac{P_6}{P_4} \right)^{(k-1)/k} = (830 \text{ K}) \left(\frac{45 \text{ kPa}}{843.5 \text{ kPa}} \right)^{0.4/1.4} = 359.3 \text{ K} \\ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{d0 (steady)}} \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_5 + V_5^2 / 2 &= h_6 + V_6^2 / 2 \\ 0 &= h_6 - h_5 + \frac{V_6^2 - V_5^2}{2} \xrightarrow{0 = c_p(T_6 - T_5) + V_6^2 / 2}\end{aligned}$$

$$\text{or } V_6 = V_{\text{exit}} = \sqrt{(2)(1.005 \text{ kJ/kg} \cdot \text{K})(518.0 - 359.3) \text{K} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 564.8 \text{ m/s}$$

The mass flow rate through the engine is

$$\begin{aligned}\nu_1 &= \frac{RT}{P} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3)(260 \text{ K})}{45 \text{ kPa}} = 1.658 \text{ m}^3/\text{kg} \\ \dot{m} &= \frac{AV_1}{\nu_1} = \frac{\pi D^2}{4} \frac{V_1}{\nu_1} = \frac{\pi(1.6 \text{ m})^2}{4} \frac{240 \text{ m/s}}{1.658 \text{ m}^3/\text{kg}} = 291.0 \text{ kg/s}\end{aligned}$$

The thrust force generated is then

$$F = \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) = (291.0 \text{ kg/s})(564.8 - 240) \text{ m/s} \left(\frac{1 \text{ N}}{1 \text{ kg} \cdot \text{m/s}^2} \right) = 94,520 \text{ N}$$

9-143 A turbojet aircraft flying at an altitude of 9150 m is operating on the ideal jet propulsion cycle. The velocity of exhaust gases, the propulsive power developed, and the rate of fuel consumption are to be determined.

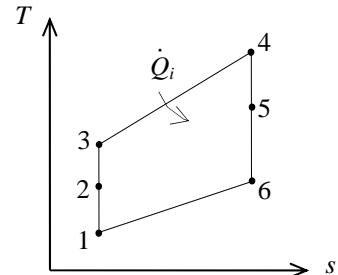

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit. 5 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 320 \text{ m/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \approx 0$).

Diffuser:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{sh0 (steady)}} \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_1 + V_1^2 / 2 &= h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \\ 0 &= c_p(T_2 - T_1) - V_1^2 / 2 \\ T_2 &= T_1 + \frac{V_1^2}{2c_p} = 241 \text{ K} + \frac{(320 \text{ m/s})^2}{(2)(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 291.9 \text{ K} \\ P_2 &= P_1 \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = (32 \text{ kPa}) \left(\frac{291.9 \text{ K}}{241 \text{ K}} \right)^{1.4/0.4} = 62.6 \text{ kPa} \end{aligned}$$

Compressor:

$$\begin{aligned} P_3 &= P_4 = (r_p)(P_2) = (12)(62.6 \text{ kPa}) = 751.2 \text{ kPa} \\ T_3 &= T_2 \left(\frac{P_3}{P_2} \right)^{(k-1)/k} = (291.9 \text{ K})(12)^{0.4/1.4} = 593.7 \text{ K} \end{aligned}$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \longrightarrow h_3 - h_2 = h_4 - h_5 \longrightarrow c_p(T_3 - T_2) = c_p(T_4 - T_5)$$

$$\text{or } T_5 = T_4 - T_3 + T_2 = 1400 - 593.7 + 291.9 = 1098.2 \text{ K}$$

Nozzle:

$$\begin{aligned} T_6 &= T_4 \left(\frac{P_6}{P_4} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{32 \text{ kPa}}{751.2 \text{ kPa}} \right)^{0.4/1.4} = 568.2 \text{ K} \\ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{sh0 (steady)}} \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_5 + V_5^2 / 2 &= h_6 + V_6^2 / 2 \\ 0 &= h_6 - h_5 + \frac{V_6^2 - V_5^2}{2} \longrightarrow 0 = c_p(T_6 - T_5) + V_6^2 / 2 \end{aligned}$$

$$\text{or } V_6 = \sqrt{(2)(1.005 \text{ kJ/kg}\cdot\text{K})(1098.2 - 568.2) \text{ K} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1032 \text{ m/s}$$

$$(b) \quad \dot{W}_p = \dot{m}(V_{\text{exit}} - V_{\text{inlet}})V_{\text{aircraft}} = (60 \text{ kg/s})(1032 - 320) \text{ m/s} (320 \text{ m/s}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 13,670 \text{ kW}$$

$$(c) \quad \dot{Q}_{\text{in}} = \dot{m}(h_4 - h_3) = \dot{m}c_p(T_4 - T_3) = (60 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1400 - 593.7) \text{ K} = 48,620 \text{ kJ/s}$$

$$\dot{m}_{\text{fuel}} = \frac{\dot{Q}_{\text{in}}}{HV} = \frac{48,620 \text{ kJ/s}}{42,700 \text{ kJ/kg}} = 1.14 \text{ kg/s}$$

9-144 A turbojet aircraft is flying at an altitude of 9150 m. The velocity of exhaust gases, the propulsive power developed, and the rate of fuel consumption are to be determined.

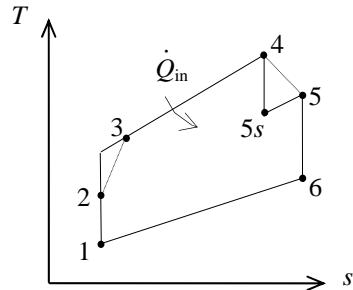

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis (a) For convenience, we assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 320 \text{ m/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \approx 0$).

Diffuser:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\phi 0} \text{ (steady)} \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ h_1 + V_1^2 / 2 &= h_2 + V_2^2 / 2 \\ 0 &= h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \\ 0 &= c_p(T_2 - T_1) - V_1^2 / 2 \end{aligned}$$

$$T_2 = T_1 + \frac{V_1^2}{2c_p} = 241 \text{ K} + \frac{(320 \text{ m/s})^2}{(2)(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 291.9 \text{ K}$$

$$P_2 = P_1 \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = (32 \text{ kPa}) \left(\frac{291.9 \text{ K}}{241 \text{ K}} \right)^{1.4/0.4} = 62.6 \text{ kPa}$$

Compressor:

$$P_3 = P_4 = (r_p)(P_2) = (12)(62.6 \text{ kPa}) = 751.2 \text{ kPa}$$

$$T_{3s} = T_2 \left(\frac{P_3}{P_2} \right)^{(k-1)/k} = (291.9 \text{ K})(12)^{0.4/1.4} = 593.7 \text{ K}$$

$$\eta_C = \frac{h_{3s} - h_2}{h_3 - h_2} = \frac{c_p(T_{3s} - T_2)}{c_p(T_3 - T_2)}$$

$$T_3 = T_2 + (T_{3s} - T_2) / \eta_C = 291.9 + (593.7 - 291.9) / (0.80) = 669.2 \text{ K}$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \longrightarrow h_3 - h_2 = h_4 - h_5 \longrightarrow c_p(T_3 - T_2) = c_p(T_4 - T_5)$$

or,

$$T_5 = T_4 - T_3 + T_2 = 1400 - 669.2 + 291.9 = 1022.7 \text{ K}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} = \frac{c_p(T_4 - T_5)}{c_p(T_4 - T_{5s})}$$

$$T_{5s} = T_4 - (T_4 - T_5) / \eta_T = 1400 - (1400 - 1022.7) / 0.85 = 956.1 \text{ K}$$

$$P_5 = P_4 \left(\frac{T_{5s}}{T_4} \right)^{k/(k-1)} = (751.2 \text{ kPa}) \left(\frac{956.1 \text{ K}}{1400 \text{ K}} \right)^{1.4/0.4} = 197.7 \text{ kPa}$$

Nozzle:

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (1022.7 \text{ K}) \left(\frac{32 \text{ kPa}}{197.7 \text{ kPa}} \right)^{0.4/1.4} = 607.8 \text{ K}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{0 (steady)}}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_5 + V_5^2 / 2 = h_6 + V_6^2 / 2$$

$$0 = h_6 - h_5 + \frac{V_6^2 - V_5^2}{2}$$

$$0 = c_p (T_6 - T_5) + V_6^2 / 2$$

or,

$$V_6 = \sqrt{(2)(1.005 \text{ kJ/kg} \cdot \text{K})(1022.7 - 607.8) \text{K} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{913.2 \text{ m/s}}$$

$$(b) \quad \dot{W}_p = \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) V_{\text{aircraft}}$$

$$= (60 \text{ kg/s})(913.2 - 320) \text{m/s} (320 \text{ m/s}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$= \mathbf{11,390 \text{ kW}}$$

$$(c) \quad \dot{Q}_{\text{in}} = \dot{m}(h_4 - h_3) = \dot{m}c_p(T_4 - T_3) = (60 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(1400 - 669.2) \text{K} = 44,067 \text{ kJ/s}$$

$$\dot{m}_{\text{fuel}} = \frac{\dot{Q}_{\text{in}}}{HV} = \frac{44,067 \text{ kJ/s}}{42,700 \text{ kJ/kg}} = \mathbf{1.03 \text{ kg/s}}$$

9-145 A turbojet aircraft that has a pressure rate of 9 is stationary on the ground. The force that must be applied on the brakes to hold the plane stationary is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with variable specific heats. 4 Kinetic and potential energies are negligible, except at the nozzle exit.

Properties The properties of air are given in Table A-17.

Analysis (a) Using variable specific heats for air,

Compressor:

$$T_1 = 290 \text{ K} \longrightarrow h_1 = 290.16 \text{ kJ/kg}$$

$$P_{r_1} = 1.2311$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (9)(1.2311) = 11.08 \longrightarrow h_2 = 544.07 \text{ kJ/kg}$$

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{fuel}} \times \text{HV} = (0.5 \text{ kg/s})(42,700 \text{ kJ/kg}) = 21,350 \text{ kJ/s}$$

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{21,350 \text{ kJ/s}}{20 \text{ kg/s}} = 1067.5 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 \longrightarrow h_3 = h_2 + q_{\text{in}} = 544.07 + 1067.5 = 1611.6 \text{ kJ/kg} \longrightarrow P_{r_3} = 568.5$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \longrightarrow h_2 - h_1 = h_3 - h_4$$

or

$$h_4 = h_3 - h_2 + h_1 = 1611.6 - 544.07 + 290.16 = 1357.7 \text{ kJ/kg}$$

Nozzle:

$$P_{r_5} = P_{r_3} \left(\frac{P_5}{P_3} \right) = (568.5) \left(\frac{1}{9} \right) = 63.17 \longrightarrow h_5 = 888.56 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{d0 (steady)}}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

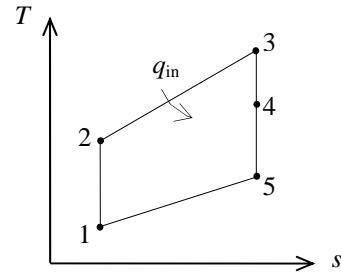

$$h_4 + V_4^2 / 2 = h_5 + V_5^2 / 2$$

$$0 = h_5 - h_4 + \frac{V_5^2 - V_4^2}{2}$$

or

$$V_5 = \sqrt{2(h_4 - h_5)} = \sqrt{(2)(1357.7 - 888.56) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 968.6 \text{ m/s}$$

$$\text{Brake force} = \text{Thrust} = \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) = (20 \text{ kg/s})(968.6 - 0) \text{ m/s} \left(\frac{1 \text{ N}}{1 \text{ kg} \cdot \text{m/s}^2} \right) = \mathbf{19,370 \text{ N}}$$

9-146 Problem 9-145 is reconsidered. The effect of compressor inlet temperature on the force that must be applied to the brakes to hold the plane stationary is to be investigated.

Analysis Using EES, the problem is solved as follows:

9-147 Air enters a turbojet engine. The thrust produced by this turbojet engine is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with variable specific heats. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit.

Properties The properties of air are given in Table A-17.

Analysis We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 300 \text{ m/s}$. Taking the entire engine as our control volume and writing the steady-flow energy balance yield

$$T_1 = 280 \text{ K} \longrightarrow h_1 = 280.13 \text{ kJ/kg}$$

$$T_2 = 700 \text{ K} \longrightarrow h_2 = 713.27 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \quad \text{for } 0 \text{ (steady)}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}(h_1 + V_1^2 / 2) = \dot{m}(h_2 + V_2^2 / 2)$$

$$\dot{Q}_{\text{in}} = \dot{m} \left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \right)$$

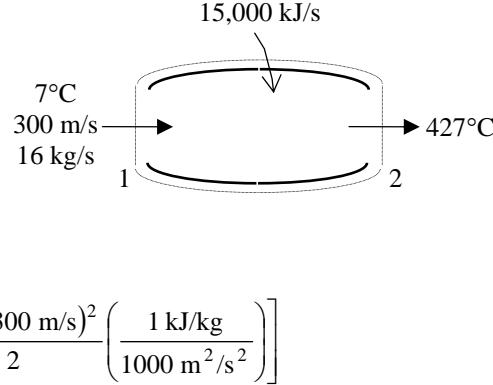

$$15,000 \text{ kJ/s} = (16 \text{ kg/s}) \left[713.27 - 280.13 + \frac{V_2^2 - (300 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right]$$

It gives

$$V_2 = 1048 \text{ m/s}$$

Thus,

$$F_p = \dot{m}(V_2 - V_1) = (16 \text{ kg/s})(1048 - 300) \text{ m/s} = \mathbf{11,968 \text{ N}}$$

Second-Law Analysis of Gas Power Cycles

9-148 The process with the highest exergy destruction for an ideal Otto cycle described in Prob. 9-36 is to be determined.

Analysis From Prob. 9-36, $q_{in} = 582.5 \text{ kJ/kg}$, $q_{out} = 253.6 \text{ kJ/kg}$, $T_1 = 288 \text{ K}$, $T_2 = 661.7 \text{ K}$, $T_3 = 1473 \text{ K}$, and $T_4 = 641.2 \text{ K}$. The exergy destruction during a process of the cycle is

$$x_{dest} = T_0 s_{gen} = T_0 \left(\Delta s - \frac{q_{in}}{T_{source}} + \frac{q_{out}}{T_{sink}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{dest,1-2} = 0 \text{ (isentropic process)}$$

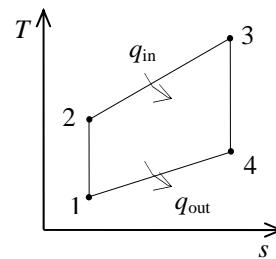

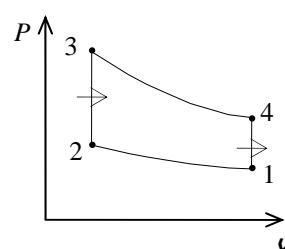

$$\begin{aligned} s_3 - s_2 &= s_4 - s_1 = c_v \ln \frac{T_3}{T_2} + R \ln \frac{v_3}{v_2} \\ &= (0.718 \text{ kJ/kg} \cdot \text{K}) \ln \frac{1473 \text{ K}}{661.7 \text{ K}} + 0 = 0.5746 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} x_{dest,2-3} &= T_0 \left(s_3 - s_2 - \frac{q_{in}}{T_{source}} \right) \\ &= (288 \text{ K}) \left(0.5746 \text{ kJ/kg} \cdot \text{K} - \frac{582.5 \text{ kJ/kg}}{1473 \text{ K}} \right) \\ &= \mathbf{51.59 \text{ kJ/kg}} \end{aligned}$$

$$x_{dest,3-4} = 0 \text{ (isentropic process)}$$

$$\begin{aligned} x_{dest,4-1} &= T_0 \left(s_1 - s_4 + \frac{q_{out}}{T_{sink}} \right) \\ &= (288 \text{ K}) \left(-0.5746 \text{ kJ/kg} \cdot \text{K} + \frac{253.6 \text{ kJ/kg}}{288 \text{ K}} \right) \\ &= \mathbf{88.12 \text{ kJ/kg}} \end{aligned}$$

The largest exergy destruction in the cycle occurs during the heat-rejection process.

9-149E The exergy destruction associated with the heat rejection process of the Diesel cycle described in Prob. 9-55E and the exergy at the end of the expansion stroke are to be determined.

Analysis From Prob. 9-55E, $q_{\text{out}} = 158.9 \text{ Btu/lbm}$, $T_1 = 540 \text{ R}$, $P_1 = 14.7 \text{ psia}$, $T_4 = 1420.6 \text{ R}$, $P_4 = 38.62 \text{ psia}$ and $\nu_4 = \nu_1$.

The entropy change during process 4-1 is

$$\begin{aligned}s_1 - s_4 &= s_1^0 @ 540 \text{ R} - s_4^0 @ 1420.6 \text{ R} - R \ln(P_1 / P_4) \\&= 0.60078 - 0.83984 - (0.06855) \ln(14.7 / 38.62) \\&= -0.1728 \text{ Btu/lbm} \cdot \text{R}\end{aligned}$$

Thus,

$$x_{\text{destroyed}, 41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = (540 \text{ R}) \left(-0.1728 \text{ Btu/lbm} \cdot \text{R} + \frac{158.9 \text{ Btu/lbm}}{540 \text{ R}} \right) = \mathbf{65.6 \text{ Btu/lbm}}$$

Noting that state 4 is identical to the state of the surroundings, the exergy at the end of the power stroke (state 4) is determined from

$$\phi_4 = (u_4 - u_0) - T_0(s_4 - s_0) + P_0(\nu_4 - \nu_0)$$

where

$$u_4 - u_0 = u_4 - u_1 = q_{\text{out}} = 158.9 \text{ Btu/lbm} \cdot \text{R}$$

$$\nu_4 - \nu_0 = \nu_4 - \nu_1 = 0$$

$$s_4 - s_0 = s_4 - s_1 = 0.1741 \text{ Btu/lbm} \cdot \text{R}$$

Thus,

$$\phi_4 = (158.9 \text{ Btu/lbm}) - (540 \text{ R})(0.1728 \text{ Btu/lbm} \cdot \text{R}) + 0 = \mathbf{65.6 \text{ Btu/lbm}}$$

Discussion Note that the exergy at state 4 is identical to the exergy destruction for the process 4-1 since state 1 is identical to the dead state, and the entire exergy at state 4 is wasted during process 4-1.

9-150 The exergy loss of each process for an ideal dual cycle described in Prob. 9-63 is to be determined.

Analysis From Prob. 9-63, $q_{in,x-3} = 114.6 \text{ kJ/kg}$, $T_1 = 291 \text{ K}$, $T_2 = 1037 \text{ K}$, $T_x = 1141 \text{ K}$, $T_3 = 1255 \text{ K}$, and $T_4 = 494.8 \text{ K}$. Also,

$$q_{in,2-x} = c_v(T_x - T_2) = (0.718 \text{ kJ/kg} \cdot \text{K})(1141 - 1037) \text{ K} = 74.67 \text{ kJ/kg}$$

$$q_{out} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg} \cdot \text{K})(494.8 - 291) \text{ K} = 146.3 \text{ kJ/kg}$$

The exergy destruction during a process of the cycle is

$$x_{dest} = T_0 s_{gen} = T_0 \left(\Delta s - \frac{q_{in}}{T_{source}} + \frac{q_{out}}{T_{sink}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{1037 \text{ K}}{291 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{5148 \text{ kPa}}{90 \text{ kPa}} \\ &= 0.1158 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$x_{dest,1-2} = T_0(s_2 - s_1) = (291 \text{ K})(0.1158 \text{ kJ/kg} \cdot \text{K}) = \mathbf{33.7 \text{ kJ/kg}}$$

$$\begin{aligned} s_x - s_2 &= c_v \ln \frac{T_x}{T_2} + R \ln \frac{v_x}{v_2} \\ &= (0.718 \text{ kJ/kg} \cdot \text{K}) \ln \frac{1141 \text{ K}}{1037 \text{ K}} + 0 = 0.06862 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$x_{dest,2-x} = T_0 \left(s_x - s_2 - \frac{q_{in,2-x}}{T_{source}} \right) = (291 \text{ K}) \left(0.06862 \text{ kJ/kg} \cdot \text{K} - \frac{74.67 \text{ kJ/kg}}{1255 \text{ K}} \right) = \mathbf{2.65 \text{ kJ/kg}}$$

$$s_3 - s_x = c_p \ln \frac{T_3}{T_x} - R \ln \frac{P_3}{P_x} = (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{1255 \text{ K}}{1141 \text{ K}} - 0 = 0.09571 \text{ kJ/kg} \cdot \text{K}$$

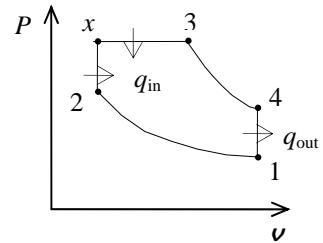

$$x_{dest,x-3} = T_0 \left(s_3 - s_x - \frac{q_{in,x-3}}{T_{source}} \right) = (291 \text{ K}) \left(0.09571 \text{ kJ/kg} \cdot \text{K} - \frac{114.6 \text{ kJ/kg}}{1255 \text{ K}} \right) = \mathbf{1.28 \text{ kJ/kg}}$$

$$\begin{aligned} s_4 - s_3 &= c_v \ln \frac{T_4}{T_3} + R \ln \frac{v_4}{v_3} = c_v \ln \frac{T_4}{T_3} + R \ln \frac{r}{r_c} \\ &= (0.718 \text{ kJ/kg} \cdot \text{K}) \ln \frac{494.8 \text{ K}}{1255 \text{ K}} + (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{18}{1.1} = 0.1339 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$x_{dest,3-4} = T_0(s_4 - s_3) = (291 \text{ K})(0.1339 \text{ kJ/kg} \cdot \text{K}) = \mathbf{39.0 \text{ kJ/kg}}$$

$$s_1 - s_4 = c_v \ln \frac{T_1}{T_4} + R \ln \frac{v_1}{v_4} = (0.718 \text{ kJ/kg} \cdot \text{K}) \ln \frac{291 \text{ K}}{494.8 \text{ K}} + 0 = -0.3811 \text{ kJ/kg} \cdot \text{K}$$

$$x_{dest,4-1} = T_0 \left(s_1 - s_4 + \frac{q_{out}}{T_{sink}} \right) = (291 \text{ K}) \left(-0.3811 \text{ kJ/kg} \cdot \text{K} + \frac{146.3 \text{ kJ/kg}}{291 \text{ K}} \right) = \mathbf{35.4 \text{ kJ/kg}}$$

9-151 The exergy loss of each process for an air-standard Stirling cycle described in Prob. 9-81 is to be determined.

Analysis From Prob. 9-81, $q_{in} = 1275 \text{ kJ/kg}$, $q_{out} = 212.5 \text{ kJ/kg}$, $T_1 = T_2 = 1788 \text{ K}$, $T_3 = T_4 = 298 \text{ K}$. The exergy destruction during a process of the cycle is

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(\Delta s - \frac{q_{in}}{T_{\text{source}}} + \frac{q_{out}}{T_{\text{sink}}} \right)$$

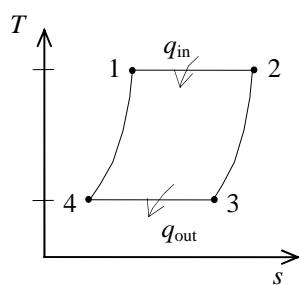

Application of this equation for each process of the cycle gives

$$\begin{aligned} s_2 - s_1 &= c_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} \\ &= 0 + (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = 0.7132 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} x_{\text{dest},1-2} &= T_0 \left(s_2 - s_1 - \frac{q_{in}}{T_{\text{source}}} \right) \\ &= (298 \text{ K}) \left(0.7132 \text{ kJ/kg} \cdot \text{K} - \frac{1275 \text{ kJ/kg}}{1788 \text{ K}} \right) = \mathbf{0.034 \text{ kJ/kg} \approx 0} \end{aligned}$$

$$\begin{aligned} s_4 - s_3 &= c_v \ln \frac{T_4}{T_3} + R \ln \frac{v_4}{v_3} \\ &= 0 + (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \left(\frac{1}{12} \right) = -0.7132 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} x_{\text{dest},3-4} &= T_0 \left(s_4 - s_3 + \frac{q_{out}}{T_{\text{sink}}} \right) \\ &= (298 \text{ K}) \left(-0.7132 \text{ kJ/kg} \cdot \text{K} + \frac{212.5 \text{ kJ/kg}}{298 \text{ K}} \right) = \mathbf{-0.034 \text{ kJ/kg} \approx 0} \end{aligned}$$

These results are not surprising since Stirling cycle is totally reversible. Exergy destructions are not calculated for processes 2-3 and 4-1 because there is no interaction with the surroundings during these processes to alter the exergy destruction.

9-152 The exergy destruction associated with each of the processes of the Brayton cycle described in Prob. 9-89 is to be determined.

Analysis From Prob. 9-89, $q_{\text{in}} = 698.3 \text{ kJ/kg}$, $q_{\text{out}} = 487.9 \text{ kJ/kg}$, and

$$T_1 = 295 \text{ K} \longrightarrow s_1^\circ = 1.68515 \text{ kJ/kg} \cdot \text{K}$$

$$h_2 = 626.60 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.44117 \text{ kJ/kg} \cdot \text{K}$$

$$T_3 = 1240 \text{ K} \longrightarrow s_3^\circ = 3.21751 \text{ kJ/kg} \cdot \text{K}$$

$$h_4 = 783.04 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.66807 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$x_{\text{destroyed},12} = T_0 s_{\text{gen},12} = T_0 (s_2 - s_1) = T_0 \left(s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) = \\ = (310 \text{ K}) (2.44117 - 1.68515 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(10)) = \mathbf{29.51 \text{ kJ/kg}}$$

$$x_{\text{destroyed},23} = T_0 s_{\text{gen},23} = T_0 \left(s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = T_0 \left(s_3^\circ - s_2^\circ - R \ln \frac{P_3}{P_2} + \frac{-q_{\text{in}}}{T_H} \right) \\ = (310 \text{ K}) \left(3.21751 - 2.44117 - \frac{698.3 \text{ kJ/kg}}{1600 \text{ K}} \right) = \mathbf{105.4 \text{ kJ/kg}}$$

$$x_{\text{destroyed},34} = T_0 s_{\text{gen},34} = T_0 (s_4 - s_3) = T_0 \left(s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) = \\ = (310 \text{ K}) (2.66807 - 3.21751 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(1/10)) = \mathbf{34.53 \text{ kJ/kg}}$$

$$x_{\text{destroyed},41} = T_0 s_{\text{gen},41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = T_0 \left(s_1^\circ - s_4^\circ - R \ln \frac{P_1}{P_4} + \frac{q_{\text{out}}}{T_L} \right) \\ = (310 \text{ K}) \left(1.68515 - 2.66807 + \frac{487.9 \text{ kJ/kg}}{310 \text{ K}} \right) = \mathbf{183.2 \text{ kJ/kg}}$$

9-153 Exergy analysis is to be used to answer the question in Prob. 9-94.

Analysis From Prob. 9-94, $T_1 = 288 \text{ K}$, $T_{2s} = 585.8 \text{ K}$, $T_2 = 618.9 \text{ K}$, $T_3 = 873 \text{ K}$, $T_{4s} = 429.2 \text{ K}$, $T_4 = 473.6 \text{ K}$, $r_p = 12$. The exergy change of a flow stream between an inlet and exit state is given by

$$\Delta\psi = h_e - h_i - T_0(s_e - s_i)$$

This is also the expression for reversible work. Application of this equation for isentropic and actual compression processes gives

$$\begin{aligned}s_{2s} - s_1 &= c_p \ln \frac{T_{2s}}{T_1} - R \ln \frac{P_2}{P_1} \\&= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{585.8 \text{ K}}{288 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) \\&= 0.0003998 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

$$\begin{aligned}w_{\text{rev},1-2s} &= c_p (T_{2s} - T_1) - T_0(s_{2s} - s_1) \\&= (1.005 \text{ kJ/kg} \cdot \text{K})(585.8 - 288) \text{ K} - (288 \text{ K})(0.0003998 \text{ kJ/kg} \cdot \text{K}) = 299.2 \text{ kJ/kg}\end{aligned}$$

$$\begin{aligned}s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\&= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{618.9 \text{ K}}{288 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = 0.05564 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

$$\begin{aligned}w_{\text{rev},1-2} &= c_p (T_2 - T_1) - T_0(s_2 - s_1) \\&= (1.005 \text{ kJ/kg} \cdot \text{K})(618.9 - 288) \text{ K} - (288 \text{ K})(0.05564 \text{ kJ/kg} \cdot \text{K}) = 316.5 \text{ kJ/kg}\end{aligned}$$

The irreversibilities therefore increase the minimum work that must be supplied to the compressor by

$$\Delta w_{\text{rev,C}} = w_{\text{rev},1-2} - w_{\text{rev},1-2s} = 316.5 - 299.2 = \mathbf{17.3 \text{ kJ/kg}}$$

Repeating the calculations for the turbine,

$$\begin{aligned}s_3 - s_{4s} &= c_p \ln \frac{T_3}{T_{4s}} - R \ln \frac{P_3}{P_4} \\&= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{873 \text{ K}}{429.2 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = 0.0003944 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

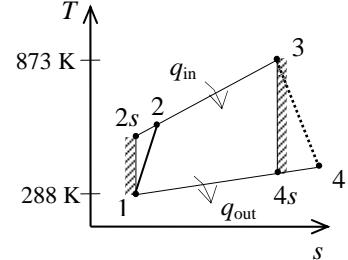

$$\begin{aligned}w_{\text{rev},3-4s} &= c_p (T_3 - T_{4s}) - T_0(s_3 - s_{4s}) \\&= (1.005 \text{ kJ/kg} \cdot \text{K})(873 - 429.2) \text{ K} - (288 \text{ K})(0.0003944 \text{ kJ/kg} \cdot \text{K}) = 445.9 \text{ kJ/kg}\end{aligned}$$

$$\begin{aligned}s_3 - s_4 &= c_p \ln \frac{T_3}{T_4} - R \ln \frac{P_3}{P_4} \\&= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{873 \text{ K}}{473.6 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = -0.09854 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

$$\begin{aligned}w_{\text{rev},3-4} &= c_p (T_3 - T_{4s}) - T_0(s_3 - s_{4s}) \\&= (1.005 \text{ kJ/kg} \cdot \text{K})(873 - 473.6) \text{ K} - (288 \text{ K})(-0.09854 \text{ kJ/kg} \cdot \text{K}) = 429.8 \text{ kJ/kg}\end{aligned}$$

$$\Delta w_{\text{rev,T}} = w_{\text{rev},3-4s} - w_{\text{rev},3-4} = 445.9 - 429.8 = \mathbf{16.1 \text{ kJ/kg}}$$

Hence, it is clear that the compressor is a little more sensitive to the irreversibilities than the turbine.

9-154 The total exergy destruction associated with the Brayton cycle described in Prob. 9-116 and the exergy at the exhaust gases at the turbine exit are to be determined.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis From Prob. 9-116, $q_{\text{in}} = 480.82$, $q_{\text{out}} = 372.73 \text{ kJ/kg}$, and

$$\begin{aligned} T_1 &= 310 \text{ K} \longrightarrow s_1^\circ = 1.73498 \text{ kJ/kg}\cdot\text{K} \\ h_2 &= 618.26 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.42763 \text{ kJ/kg}\cdot\text{K} \\ T_3 &= 1150 \text{ K} \longrightarrow s_3^\circ = 3.12900 \text{ kJ/kg}\cdot\text{K} \\ h_4 &= 803.14 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.69407 \text{ kJ/kg}\cdot\text{K} \\ h_5 &= 738.43 \text{ kJ/kg} \longrightarrow s_5^\circ = 2.60815 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

and, from an energy balance on the heat exchanger,

$$\begin{aligned} h_5 - h_2 &= h_4 - h_6 \longrightarrow h_6 = 803.14 - (738.43 - 618.26) = 682.97 \text{ kJ/kg} \\ &\longrightarrow s_6^\circ = 2.52861 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

Thus,

$$\begin{aligned} x_{\text{destroyed},12} &= T_0 s_{\text{gen},12} = T_0(s_2 - s_1) = T_0 \left(s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) \\ &= (290 \text{ K})(2.42763 - 1.73498 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(7)) = \mathbf{38.91 \text{ kJ/kg}} \\ x_{\text{destroyed},34} &= T_0 s_{\text{gen},34} = T_0(s_4 - s_3) = T_0 \left(s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) \\ &= (290 \text{ K})(2.69407 - 3.12900 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(1/7)) = \mathbf{35.83 \text{ kJ/kg}} \\ x_{\text{destroyed,regen}} &= T_0 s_{\text{gen,regen}} = T_0[(s_5 - s_2) + (s_6 - s_4)] = T_0[s_5^\circ - s_2^\circ + (s_6^\circ - s_4^\circ)] \\ &= (290 \text{ K})(2.60815 - 2.42763 + 2.52861 - 2.69407) = \mathbf{4.37 \text{ kJ/kg}} \\ x_{\text{destroyed},53} &= T_0 s_{\text{gen},53} = T_0 \left(s_3 - s_5 - \frac{q_{R,53}}{T_R} \right) = T_0 \left(s_3^\circ - s_5^\circ - R \ln \frac{P_3}{P_5} - \frac{q_{\text{in}}}{T_H} \right) \\ &= (290 \text{ K}) \left(3.12900 - 2.60815 - \frac{480.82 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{58.09 \text{ kJ/kg}} \\ x_{\text{destroyed},61} &= T_0 s_{\text{gen},61} = T_0 \left(s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = T_0 \left(s_1^\circ - s_6^\circ - R \ln \frac{P_1}{P_6} + \frac{q_{\text{out}}}{T_L} \right) \\ &= (290 \text{ K}) \left(1.73498 - 2.52861 + \frac{372.73 \text{ kJ/kg}}{290 \text{ K}} \right) = \mathbf{142.6 \text{ kJ/kg}} \end{aligned}$$

Noting that $h_0 = h_{290 \text{ K}} = 290.16 \text{ kJ/kg}$ and $T_0 = 290 \text{ K} \longrightarrow s_1^\circ = 1.66802 \text{ kJ/kg}\cdot\text{K}$, the stream exergy at the exit of the regenerator (state 6) is determined from

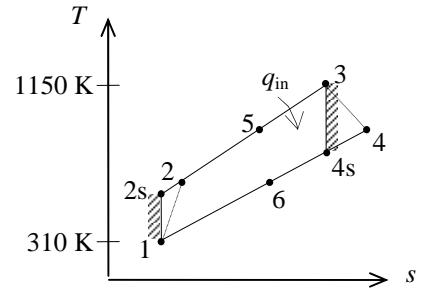

$$\phi_6 = (h_6 - h_0) - T_0(s_6 - s_0) + \frac{V_6^2}{2} + g z_6 \phi_0$$

where

$$s_6 - s_0 = s_6 - s_1 = s_6^\circ - s_1^\circ - R \ln \frac{P_6}{P_1} = 2.52861 - 1.66802 = 0.86059 \text{ kJ/kg}\cdot\text{K}$$

Thus,

$$\phi_6 = 682.97 - 290.16 - (290 \text{ K})(0.86059 \text{ kJ/kg}\cdot\text{K}) = \mathbf{143.2 \text{ kJ/kg}}$$

9-155 Prob. 9-154 is reconsidered. The effect of the cycle pressure on the total irreversibility for the cycle and the exergy of the exhaust gas leaving the regenerator is to be investigated.

Analysis Using EES, the problem is solved as follows:

9-156 The exergy loss of each process for a regenerative Brayton cycle with three stages of reheating and intercooling described in Prob. 9-135 is to be determined.

Analysis From Prob. 9-135,

$$r_p = 4, q_{in,7-8} = q_{in,9-10} = q_{in,11-12} = 300 \text{ kJ/kg},$$

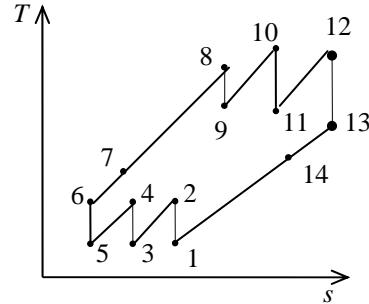

$$q_{out,14-1} = 206.9 \text{ kJ/kg}, q_{out,2-3} = q_{out,4-5} = 141.6 \text{ kJ/kg},$$

$$T_1 = T_3 = T_5 = 290 \text{ K}, T_2 = T_4 = T_6 = 430.9 \text{ K}$$

$$T_7 = 520.7 \text{ K}, T_8 = 819.2 \text{ K}, T_9 = 551.3 \text{ K}$$

$$T_{10} = 849.8 \text{ K}, T_{11} = 571.9 \text{ K}, T_{12} = 870.4 \text{ K},$$

$$T_{13} = 585.7 \text{ K}, T_{14} = 495.9 \text{ K}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} x_{\text{dest},1-2} &= x_{\text{dest},3-4} = x_{\text{dest},5-6} = T_0 \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) \\ &= (290) \left[(1.005) \ln \frac{430.9}{290} - (0.287) \ln(4) \right] = \mathbf{0.03 \text{ kJ/kg} \approx 0} \end{aligned}$$

$$x_{\text{dest},7-8} = T_0 \left(c_p \ln \frac{T_8}{T_7} - R \ln \frac{P_8}{P_7} - \frac{q_{\text{in},7-8}}{T_{\text{source}}} \right) = (290) \left[(1.005) \ln \frac{819.2}{520.7} - 0 - \frac{300}{870.4} \right] = \mathbf{32.1 \text{ kJ/kg}}$$

$$x_{\text{dest},9-10} = T_0 \left(c_p \ln \frac{T_{10}}{T_9} - R \ln \frac{P_8}{P_7} - \frac{q_{\text{in},9-10}}{T_{\text{source}}} \right) = (290) \left[(1.005) \ln \frac{849.8}{551.3} - 0 - \frac{300}{870.4} \right] = \mathbf{26.2 \text{ kJ/kg}}$$

$$x_{\text{dest},11-12} = T_0 \left(c_p \ln \frac{T_{12}}{T_{11}} - R \ln \frac{P_{12}}{P_{11}} - \frac{q_{\text{in},11-12}}{T_{\text{source}}} \right) = (290) \left[(1.005) \ln \frac{870.4}{571.9} - 0 - \frac{300}{870.4} \right] = \mathbf{22.5 \text{ kJ/kg}}$$

$$x_{\text{dest},8-9} = T_0 \left(c_p \ln \frac{T_9}{T_8} - R \ln \frac{P_9}{P_8} \right) = (290) \left[(1.005) \ln \frac{551.3}{819.2} - (0.287) \ln \left(\frac{1}{4} \right) \right] = \mathbf{-0.05 \text{ kJ/kg} \approx 0}$$

$$x_{\text{dest},10-11} = T_0 \left(c_p \ln \frac{T_{11}}{T_{10}} - R \ln \frac{P_{11}}{P_{10}} \right) = (290) \left[(1.005) \ln \frac{571.9}{849.8} - (0.287) \ln \left(\frac{1}{4} \right) \right] = \mathbf{-0.04 \text{ kJ/kg} \approx 0}$$

$$x_{\text{dest},12-13} = T_0 \left(c_p \ln \frac{T_{13}}{T_{12}} - R \ln \frac{P_{13}}{P_{12}} \right) = (290) \left[(1.005) \ln \frac{585.7}{870.4} - (0.287) \ln \left(\frac{1}{4} \right) \right] = \mathbf{-0.08 \text{ kJ/kg} \approx 0}$$

$$x_{\text{dest},14-1} = T_0 \left(c_p \ln \frac{T_1}{T_{14}} - R \ln \frac{P_1}{P_{14}} + \frac{q_{\text{out},14-1}}{T_{\text{sink}}} \right) = (290) \left[(1.005) \ln \frac{290}{495.9} - 0 + \frac{206.9}{290} \right] = \mathbf{50.6 \text{ kJ/kg}}$$

$$x_{\text{dest},2-3} = x_{\text{dest},4-5} = T_0 \left(c_p \ln \frac{T_3}{T_2} - R \ln \frac{P_3}{P_2} + \frac{q_{\text{out},2-3}}{T_{\text{sink}}} \right) = (290) \left[(1.005) \ln \frac{290}{430.9} - 0 + \frac{141.6}{290} \right] = \mathbf{26.2 \text{ kJ/kg}}$$

$$x_{\text{dest,regen}} = T_0 (\Delta s_{6-7} + \Delta s_{13-14}) = T_0 \left(c_p \ln \frac{T_7}{T_6} + c_p \ln \frac{T_{14}}{T_{13}} \right)$$

$$= (290) \left[(1.005) \ln \frac{520.7}{430.9} + (1.005) \ln \frac{495.9}{585.7} \right] = \mathbf{6.66 \text{ kJ/kg}}$$

9-157 A gas-turbine plant uses diesel fuel and operates on simple Brayton cycle. The isentropic efficiency of the compressor, the net power output, the back work ratio, the thermal efficiency, and the second-law efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at $500^{\circ}\text{C} = 773 \text{ K}$ are $c_p = 1.093 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.806 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.357$ (Table A-2b).

Analysis (a) The isentropic efficiency of the compressor may be determined if we first calculate the exit temperature for the isentropic case

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (303 \text{ K}) \left(\frac{700 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.357-1)/1.357} = 505.6 \text{ K}$$

$$\eta_C = \frac{T_{2s} - T_1}{T_2 - T_1} = \frac{(505.6 - 303) \text{ K}}{(533 - 303) \text{ K}} = \mathbf{0.881}$$

(b) The total mass flowing through the turbine and the rate of heat input are

$$\dot{m}_t = \dot{m}_a + \dot{m}_f = \dot{m}_a + \frac{\dot{m}_a}{AF} = 12.6 \text{ kg/s} + \frac{12.6 \text{ kg/s}}{60} = 12.6 \text{ kg/s} + 0.21 \text{ kg/s} = 12.81 \text{ kg/s}$$

$$\dot{Q}_{in} = \dot{m}_f q_{HV} \eta_c = (0.21 \text{ kg/s})(42,000 \text{ kJ/kg})(0.97) = 8555 \text{ kW}$$

The temperature at the exit of combustion chamber is

$$\dot{Q}_{in} = \dot{m} c_p (T_3 - T_2) \longrightarrow 8555 \text{ kJ/s} = (12.81 \text{ kg/s})(1.093 \text{ kJ/kg}\cdot\text{K})(T_3 - 533) \text{ K} \longrightarrow T_3 = 1144 \text{ K}$$

The temperature at the turbine exit is determined using isentropic efficiency relation

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1144 \text{ K}) \left(\frac{100 \text{ kPa}}{700 \text{ kPa}} \right)^{(1.357-1)/1.357} = 685.7 \text{ K}$$

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow 0.85 = \frac{(1144 - T_4) \text{ K}}{(1144 - 685.7) \text{ K}} \longrightarrow T_4 = 754.4 \text{ K}$$

The net power and the back work ratio are

$$\dot{W}_{C,in} = \dot{m}_a c_p (T_2 - T_1) = (12.6 \text{ kg/s})(1.093 \text{ kJ/kg}\cdot\text{K})(533 - 303) \text{ K} = 3168 \text{ kW}$$

$$\dot{W}_{T,out} = \dot{m} c_p (T_3 - T_4) = (12.81 \text{ kg/s})(1.093 \text{ kJ/kg}\cdot\text{K})(1144 - 754.4) \text{ K} = 5455 \text{ kW}$$

$$\dot{W}_{net} = \dot{W}_{T,out} - \dot{W}_{C,in} = 5455 - 3168 = \mathbf{2287 \text{ kW}}$$

$$r_{bw} = \frac{\dot{W}_{C,in}}{\dot{W}_{T,out}} = \frac{3168 \text{ kW}}{5455 \text{ kW}} = \mathbf{0.581}$$

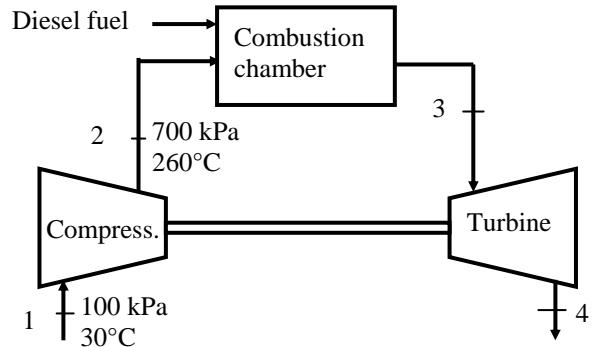

(c) The thermal efficiency is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{2287 \text{ kW}}{8555 \text{ kW}} = \mathbf{0.267}$$

The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). The maximum temperature for the cycle can be taken to be the turbine inlet temperature. That is,

$$\eta_{max} = 1 - \frac{T_1}{T_3} = 1 - \frac{303 \text{ K}}{1144 \text{ K}} = 0.735$$

$$\text{and } \eta_{II} = \frac{\eta_{th}}{\eta_{max}} = \frac{0.267}{0.735} = \mathbf{0.364}$$

9-158 A modern compression ignition engine operates on the ideal dual cycle. The maximum temperature in the cycle, the net work output, the thermal efficiency, the mean effective pressure, the net power output, the second-law efficiency of the cycle, and the rate of exergy of the exhaust gases are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at 1000 K are $c_p = 1.142 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.855 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.336$ (Table A-2b).

Analysis (a) The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{V_c + V_d}{V_c} \rightarrow 16 = \frac{V_c + 0.0018 \text{ m}^3}{V_c} \rightarrow V_c = 0.00012 \text{ m}^3 = V_2 = V_x$$

$$V_1 = V_c + V_d = 0.00012 + 0.0018 = 0.00192 \text{ m}^3 = V_4$$

Process 1-2: Isentropic compression

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (343 \text{ K})(16)^{1.336-1} = 870.7 \text{ K}$$

$$P_2 = P_1 \left(\frac{V_1}{V_2} \right)^k = (95 \text{ kPa})(16)^{1.336} = 3859 \text{ kPa}$$

Process 2-x and x-3: Constant-volume and constant pressure heat addition processes:

$$T_x = T_2 \frac{P_x}{P_2} = (870.7 \text{ K}) \frac{7500 \text{ kPa}}{3859 \text{ kPa}} = 1692 \text{ K}$$

$$q_{2-x} = c_v(T_x - T_2) = (0.855 \text{ kJ/kg}\cdot\text{K})(1692 - 870.7) \text{ K} = 702.6 \text{ kJ/kg}$$

$$q_{2-x} = q_{x-3} = c_p(T_3 - T_x) \rightarrow 702.6 \text{ kJ/kg} = (0.855 \text{ kJ/kg}\cdot\text{K})(T_3 - 1692) \text{ K} \rightarrow T_3 = 2308 \text{ K}$$

$$(b) \quad q_{in} = q_{2-x} + q_{x-3} = 702.6 + 702.6 = 1405 \text{ kJ/kg}$$

$$V_3 = V_x \frac{T_3}{T_x} = (0.00012 \text{ m}^3) \frac{2308 \text{ K}}{1692 \text{ K}} = 0.0001636 \text{ m}^3$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = (2308 \text{ K}) \left(\frac{0.0001636 \text{ m}^3}{0.00192 \text{ m}^3} \right)^{1.336-1} = 1009 \text{ K}$$

$$P_4 = P_3 \left(\frac{V_3}{V_4} \right)^k = (7500 \text{ kPa}) \left(\frac{0.0001636 \text{ m}^3}{0.00192 \text{ m}^3} \right)^{1.336} = 279.4 \text{ kPa}$$

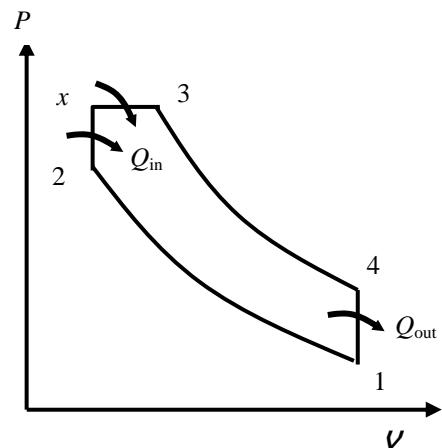

Process 4-1: constant volume heat rejection.

$$q_{out} = c_v(T_4 - T_1) = (0.855 \text{ kJ/kg}\cdot\text{K})(1009 - 343) \text{ K} = 569.3 \text{ kJ/kg}$$

The net work output and the thermal efficiency are

$$w_{net,out} = q_{in} - q_{out} = 1405 - 569.3 = 835.8 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{835.8 \text{ kJ/kg}}{1405 \text{ kJ/kg}} = 0.5948 = 59.5\%$$

(c) The mean effective pressure is determined to be

$$m = \frac{P_1 V_1}{RT_1} = \frac{(95 \text{ kPa})(0.00192 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(343 \text{ K})} = 0.001853 \text{ kg}$$

$$\text{MEP} = \frac{mw_{\text{net,out}}}{V_1 - V_2} = \frac{(0.001853 \text{ kg})(835.8 \text{ kJ/kg})}{(0.00192 - 0.00012)\text{m}^3} \left(\frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = \mathbf{860.4 \text{ kPa}}$$

(d) The power for engine speed of 3500 rpm is

$$\dot{W}_{\text{net}} = mw_{\text{net}} \frac{\dot{n}}{2} = (0.001853 \text{ kg})(835.8 \text{ kJ/kg}) \frac{2200 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left(\frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{28.39 \text{ kW}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). We take the dead state temperature and pressure to be 25°C and 100 kPa.

$$\eta_{\text{max}} = 1 - \frac{T_0}{T_3} = 1 - \frac{(25 + 273) \text{ K}}{2308 \text{ K}} = 0.8709$$

and

$$\eta_{\text{II}} = \frac{\eta_{\text{th}}}{\eta_{\text{max}}} = \frac{0.5948}{0.8709} = 0.683 = \mathbf{68.3\%}$$

The rate of exergy of the exhaust gases is determined as follows

$$\begin{aligned} x_4 &= u_4 - u_0 - T_0(s_4 - s_0) = c_v(T_4 - T_0) - T_0 \left[c_p \ln \frac{T_4}{T_0} - R \ln \frac{P_4}{P_0} \right] \\ &= (0.855)(1009 - 298) - (298) \left[(1.142 \text{ kJ/kg.K}) \ln \frac{1009}{298} - (0.287 \text{ kJ/kg.K}) \ln \frac{279.4}{100} \right] = 285.0 \text{ kJ/kg} \\ \dot{X}_4 &= mx_4 \frac{\dot{n}}{2} = (0.001853 \text{ kg})(285.0 \text{ kJ/kg}) \frac{2200 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left(\frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{9.683 \text{ kW}} \end{aligned}$$

Review Problems

9-159 An Otto cycle with a compression ratio of 7 is considered. The thermal efficiency is to be determined using constant and variable specific heats.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis (a) Constant specific heats:

$$\eta_{th} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{7^{1.4-1}} = 0.5408 = \mathbf{54.1\%}$$

(b) Variable specific heats: (using air properties from Table A-17)

Process 1-2: isentropic compression.

$$T_1 = 288 \text{ K} \longrightarrow u_1 = 205.48 \text{ kJ/kg}$$

$$v_{r1} = 688.1$$

$$v_{r2} = \frac{v_2}{v_1} v_{r2} = \frac{1}{r} v_{r2} = \frac{1}{7} (688.1) = 98.3 \longrightarrow u_2 = 447.62 \text{ kJ/kg}$$

Process 2-3: $v = \text{constant}$ heat addition.

$$T_3 = 1273 \text{ K} \longrightarrow u_3 = 998.51 \text{ kJ/kg}$$

$$v_{r3} = 12.045$$

$$q_{in} = u_3 - u_2 = 998.51 - 447.62 = 550.89 \text{ kJ/kg}$$

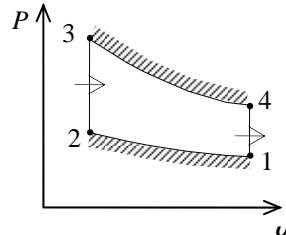

Process 3-4: isentropic expansion.

$$v_{r4} = \frac{v_4}{v_3} v_{r3} = r v_{r3} = (7)(12.045) = 84.32 \longrightarrow u_4 = 475.54 \text{ kJ/kg}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{out} = u_4 - u_1 = 475.54 - 205.48 = 270.06 \text{ kJ/kg}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{270.06 \text{ kJ/kg}}{550.89 \text{ kJ/kg}} = 0.5098 = \mathbf{51.0\%}$$

9-160E An ideal diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency is to be determined using constant and variable specific heats.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$, $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$, $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis (a) Constant specific heats:

Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (505 \text{ R}) (20)^{0.4} = 1673.8 \text{ R}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow \frac{\nu_3}{\nu_2} = \frac{T_3}{T_2} = \frac{2260 \text{ R}}{1673.8 \text{ R}} = 1.350$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = T_3 \left(\frac{1.350 \nu_2}{\nu_4} \right)^{k-1} = T_3 \left(\frac{1.350}{r} \right)^{k-1} = (2260 \text{ R}) \left(\frac{1.350}{20} \right)^{0.4} = 768.8 \text{ R}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (0.240 \text{ Btu/lbm}\cdot\text{R})(2260 - 1673.8) \text{ R} = 140.7 \text{ Btu/lbm}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.171 \text{ Btu/lbm}\cdot\text{R})(768.8 - 505) \text{ R} = 45.11 \text{ Btu/lbm}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 140.7 - 45.11 = 95.59 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{95.59 \text{ Btu/lbm}}{140.7 \text{ Btu/lbm}} = 0.6794 = \mathbf{67.9\%}$$

(b) Variable specific heats: (using air properties from Table A-17)

Process 1-2: isentropic compression.

$$T_1 = 505 \text{ R} \longrightarrow \begin{aligned} u_1 &= 86.06 \text{ Btu/lbm} \\ \nu_{r1} &= 170.82 \end{aligned}$$

$$\nu_{r2} = \frac{\nu_2}{\nu_1} \nu_{r1} = \frac{1}{r} \nu_{r1} = \frac{1}{20} (170.82) = 8.541 \longrightarrow \begin{aligned} T_2 &= 1582.3 \text{ R} \\ h_2 &= 391.01 \text{ Btu/lbm} \end{aligned}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow \frac{\nu_3}{\nu_2} = \frac{T_3}{T_2} = \frac{2260 \text{ R}}{1582.3 \text{ R}} = 1.428$$

$$T_3 = 2260 \text{ R} \longrightarrow \begin{aligned} h_3 &= 577.52 \text{ Btu/lbm} \\ \nu_{r3} &= 2.922 \end{aligned}$$

$$q_{\text{in}} = h_3 - h_2 = 577.52 - 391.01 = 186.51 \text{ Btu/lbm}$$

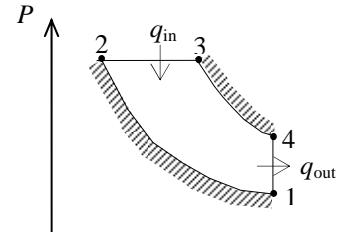

Process 3-4: isentropic expansion.

$$\nu_{r4} = \frac{\nu_4}{\nu_3} \nu_{r3} = \frac{\nu_4}{1.428 \nu_2} \nu_{r3} = \frac{r}{1.428} \nu_{r3} = \frac{20}{1.428} (2.922) = 40.92 \longrightarrow u_4 = 152.65 \text{ Btu/lbm}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 152.65 - 86.06 = 66.59 \text{ Btu/lbm}$$

$$\text{Then } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{66.59 \text{ Btu/lbm}}{186.51 \text{ Btu/lbm}} = 0.6430 = \mathbf{64.3\%}$$

9-161E A simple ideal Brayton cycle with air as the working fluid operates between the specified temperature limits. The net work is to be determined using constant and variable specific heats.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis (a) Constant specific heats:

$$T_2 = T_1 r_p^{(k-1)/k} = (480 \text{ R})(12)^{0.4/1.4} = 976.3 \text{ R}$$

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1460 \text{ R}) \left(\frac{1}{12} \right)^{0.4/1.4} = 717.8 \text{ R}$$

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb}} - w_{\text{comp}} \\ &= c_p (T_3 - T_4) - c_p (T_2 - T_1) \\ &= c_p (T_3 - T_4 + T_1 - T_2) \\ &= (0.240 \text{ Btu/lbm}\cdot\text{R})(1460 - 717.8 + 480 - 976.3) \text{ R} \\ &= \mathbf{59.0 \text{ Btu/lbm}} \end{aligned}$$

(b) Variable specific heats: (using air properties from Table A-17E)

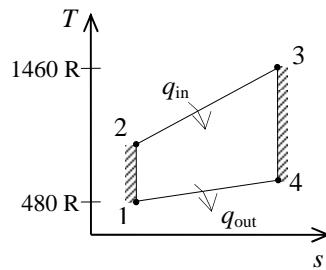

$$\begin{aligned} T_1 = 480 \text{ R} &\longrightarrow h_1 = 114.69 \text{ Btu/lbm} \\ P_{r1} = 0.9182 & \end{aligned}$$

$$P_{r2} = \frac{P_2}{P_1} P_{r1} = (12)(0.9182) = 11.02 \longrightarrow h_2 = 233.63 \text{ Btu/lbm}$$

$$\begin{aligned} T_3 = 1460 \text{ R} &\longrightarrow h_3 = 358.63 \text{ Btu/lbm} \\ P_{r3} = 50.40 & \end{aligned}$$

$$P_{r4} = \frac{P_4}{P_3} P_{r3} = \left(\frac{1}{12} \right)(50.40) = 4.12 \longrightarrow h_4 = 176.32 \text{ Btu/lbm}$$

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb}} - w_{\text{comp}} \\ &= (h_3 - h_4) - (h_2 - h_1) \\ &= (358.63 - 176.32) - (233.63 - 114.69) \\ &= \mathbf{63.4 \text{ Btu/lbm}} \end{aligned}$$

9-162 A turbocharged four-stroke V-16 diesel engine produces 3500 hp at 1200 rpm. The amount of power produced per cylinder per mechanical and per thermodynamic cycle is to be determined.

Analysis Noting that there are 16 cylinders and each thermodynamic cycle corresponds to 2 mechanical cycles (revolutions), we have

(a)

$$\begin{aligned} w_{\text{mechanical}} &= \frac{\text{Total power produced}}{(\text{No. of cylinders})(\text{No. of mechanical cycles})} \\ &= \frac{3500 \text{ hp}}{(16 \text{ cylinders})(1200 \text{ rev/min})} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) \\ &= \mathbf{7.73 \text{ Btu/cyl} \cdot \text{mech cycle}} \quad (= 8.16 \text{ kJ/cyl} \cdot \text{mech cycle}) \end{aligned}$$

(b)

$$\begin{aligned} w_{\text{thermodynamic}} &= \frac{\text{Total power produced}}{(\text{No. of cylinders})(\text{No. of thermodynamic cycles})} \\ &= \frac{3500 \text{ hp}}{(16 \text{ cylinders})(1200/2 \text{ rev/min})} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) \\ &= \mathbf{15.46 \text{ Btu/cyl} \cdot \text{therm cycle}} \quad (= 16.31 \text{ kJ/cyl} \cdot \text{therm cycle}) \end{aligned}$$

9-163 A simple ideal Brayton cycle operating between the specified temperature limits is considered. The pressure ratio for which the compressor and the turbine exit temperature of air are equal is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$ (Table A-2).

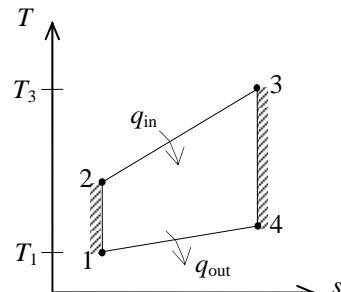

Analysis We treat air as an ideal gas with constant specific heats. Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$\begin{aligned} T_2 &= T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k} \\ T_4 &= T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} \end{aligned}$$

Setting $T_2 = T_4$ and solving for r_p gives

$$r_p = \left(\frac{T_3}{T_1} \right)^{k/2(k-1)} = \left(\frac{1500 \text{ K}}{300 \text{ K}} \right)^{1.4/0.8} = \mathbf{16.7}$$

Therefore, the compressor and turbine exit temperatures will be equal when the compression ratio is 16.7.

9-164 A four-cylinder spark-ignition engine with a compression ratio of 8 is considered. The amount of heat supplied per cylinder, the thermal efficiency, and the rpm for a net power output of 60 kW are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The properties of air are given in Table A-17.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 310 \text{ K} \longrightarrow u_1 = 221.25 \text{ kJ/kg}$$

$$\nu_{r_1} = 572.3$$

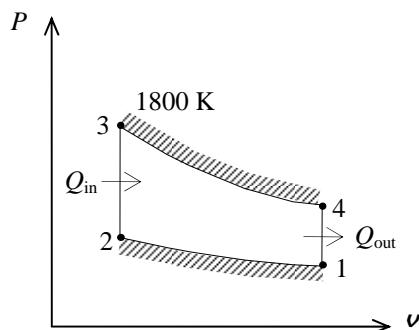

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{10.5} (572.3) = 54.50$$

$$\longrightarrow u_2 = 564.29 \text{ kJ/kg}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$T_3 = 2100 \text{ K} \longrightarrow u_3 = 1775.3 \text{ kJ/kg}$$

$$\nu_{r_3} = 2.356$$

$$m = \frac{P_1 \nu_1}{RT_1} = \frac{(98 \text{ kPa})(0.0004 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(310 \text{ K})} = 4.406 \times 10^{-4} \text{ kg}$$

$$Q_{\text{in}} = m(u_3 - u_2) = (4.406 \times 10^{-4} \text{ kg})(1775.3 - 564.29) \text{ kJ/kg} = \mathbf{0.5336 \text{ kJ}}$$

(b) Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = r \nu_{r_3} = (10.5)(2.356) = 24.74 \longrightarrow u_4 = 764.05 \text{ kJ/kg}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = (4.406 \times 10^{-4} \text{ kg})(764.05 - 221.25) \text{ kJ/kg} = 0.2392 \text{ kJ}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 0.5336 - 0.2392 = 0.2944 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{0.2944 \text{ kJ}}{0.5336 \text{ kJ}} = 0.5517 = \mathbf{55.2\%}$$

$$(c) \quad \dot{n} = 2 \frac{\dot{W}_{\text{net}}}{n_{\text{cyl}} W_{\text{net,cyl}}} = (2 \text{ rev/cycle}) \frac{45 \text{ kJ/s}}{4 \times (0.2944 \text{ kJ/cycle})} \left(\frac{60 \text{ s}}{1 \text{ min}} \right) = \mathbf{4586 \text{ rpm}}$$

Note that for four-stroke cycles, there are two revolutions per cycle.

9-165 Problem 9-164 is reconsidered. The effect of the compression ratio net work done and the efficiency of the cycle is to be investigated. Also, the $T-s$ and $P-v$ diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

9-166 An ideal gas Carnot cycle with helium as the working fluid is considered. The pressure ratio, compression ratio, and minimum temperature of the energy source are to be determined.

Assumptions 1 Kinetic and potential energy changes are negligible. 2 Helium is an ideal gas with constant specific heats.

Properties The specific heat ratio of helium is $k = 1.667$ (Table A-2a).

Analysis From the definition of the thermal efficiency of a Carnot heat engine,

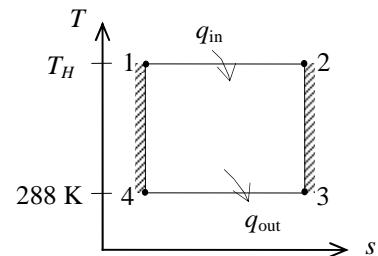

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} \longrightarrow T_H = \frac{T_L}{1 - \eta_{\text{th,Carnot}}} = \frac{(15 + 273) \text{ K}}{1 - 0.50} = \mathbf{576 \text{ K}}$$

An isentropic process for an ideal gas is one in which Pv^k remains constant. Then, the pressure ratio is

$$\frac{P_2}{P_1} = \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = \left(\frac{576 \text{ K}}{288 \text{ K}} \right)^{1.667/(1.667-1)} = \mathbf{5.65}$$

Based on the process equation, the compression ratio is

$$\frac{\nu_1}{\nu_2} = \left(\frac{P_2}{P_1} \right)^{1/k} = (5.65)^{1/1.667} = \mathbf{2.83}$$

9-167E An ideal gas Carnot cycle with helium as the working fluid is considered. The pressure ratio, compression ratio, and minimum temperature of the energy-source reservoir are to be determined.

Assumptions 1 Kinetic and potential energy changes are negligible. 2 Helium is an ideal gas with constant specific heats.

Properties The specific heat ratio of helium is $k = 1.667$ (Table A-2Ea).

Analysis From the definition of the thermal efficiency of a Carnot heat engine,

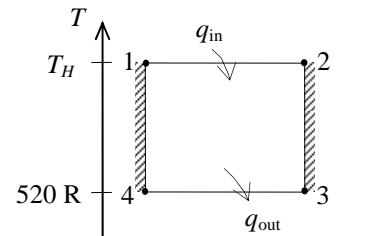

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} \longrightarrow T_H = \frac{T_L}{1 - \eta_{\text{th,Carnot}}} = \frac{(60 + 460) \text{ R}}{1 - 0.60} = \mathbf{1300 \text{ R}}$$

An isentropic process for an ideal gas is one in which Pv^k remains constant. Then, the pressure ratio is

$$\frac{P_2}{P_1} = \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = \left(\frac{1300 \text{ R}}{520 \text{ R}} \right)^{1.667/(1.667-1)} = \mathbf{9.88}$$

Based on the process equation, the compression ratio is

$$\frac{\nu_1}{\nu_2} = \left(\frac{P_2}{P_1} \right)^{1/k} = (9.88)^{1/1.667} = \mathbf{3.95}$$

9-168 The compression ratio required for an ideal Otto cycle to produce certain amount of work when consuming a given amount of fuel is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats. **4** The combustion efficiency is 100 percent.

Properties The properties of air at room temperature are $k = 1.4$ (Table A-2).

Analysis The heat input to the cycle for 0.043 grams of fuel consumption is

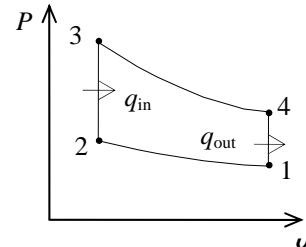

$$Q_{\text{in}} = m_{\text{fuel}} q_{\text{HV}} = (0.035 \times 10^{-3} \text{ kg})(43,000 \text{ kJ/kg}) = 1.505 \text{ kJ}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{1 \text{ kJ}}{1.505 \text{ kJ}} = 0.6645$$

From the definition of thermal efficiency, we obtain the required compression ratio to be

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \longrightarrow r = \frac{1}{(1 - \eta_{\text{th}})^{1/(k-1)}} = \frac{1}{(1 - 0.6645)^{1/(1.4-1)}} = \mathbf{15.3}$$

9-169 An ideal Otto cycle with air as the working fluid with a compression ratio of 9.2 is considered. The amount of heat transferred to the air, the net work output, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The properties of air are given in Table A-17.

Analysis (a) Process 1-2: isentropic compression.

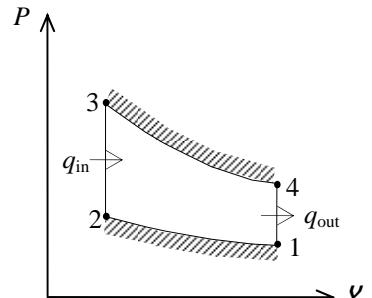

$$T_1 = 300 \text{ K} \longrightarrow u_1 = 214.07 \text{ kJ/kg}$$

$$\nu_{r_1} = 621.2$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{9.2} (621.2) = 67.52 \longrightarrow T_2 = 708.3 \text{ K}$$

$$u_2 = 518.9 \text{ kJ/kg}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (9.2) \left(\frac{708.3 \text{ K}}{300 \text{ K}} \right) (98 \text{ kPa}) = 2129 \text{ kPa}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow T_3 = \frac{P_3}{P_2} T_2 = 2T_2 = (2)(708.3) = 1416.6 \text{ K} \longrightarrow u_3 = 1128.7 \text{ kJ/kg}$$

$$\nu_{r_3} = 8.593$$

$$q_{in} = u_3 - u_2 = 1128.7 - 518.9 = \mathbf{609.8 \text{ kJ/kg}}$$

(b) Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = r \nu_{r_3} = (9.2)(8.593) = 79.06 \longrightarrow u_4 = 487.75 \text{ kJ/kg}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{out} = u_4 - u_1 = 487.75 - 214.07 = 273.7 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 609.8 - 273.7 = \mathbf{336.1 \text{ kJ/kg}}$$

$$(c) \eta_{th} = \frac{w_{net}}{q_{in}} = \frac{336.1 \text{ kJ/kg}}{609.8 \text{ kJ/kg}} = \mathbf{55.1\%}$$

$$(d) \nu_{max} = \nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})}{98 \text{ kPa}} = 0.879 \text{ m}^3/\text{kg}$$

$$\nu_{min} = \nu_2 = \frac{\nu_{max}}{r}$$

$$\text{MEP} = \frac{w_{net}}{\nu_1 - \nu_2} = \frac{w_{net}}{\nu_1(1-1/r)} = \frac{336.1 \text{ kJ/kg}}{(0.879 \text{ m}^3/\text{kg})(1-1/9.2)} \left(\frac{1 \text{ kPa} \cdot \text{m}^3}{1 \text{ kJ}} \right) = \mathbf{429 \text{ kPa}}$$

9-170 An ideal Otto cycle with air as the working fluid with a compression ratio of 9.2 is considered. The amount of heat transferred to the air, the net work output, the thermal efficiency, and the mean effective pressure are to be determined.

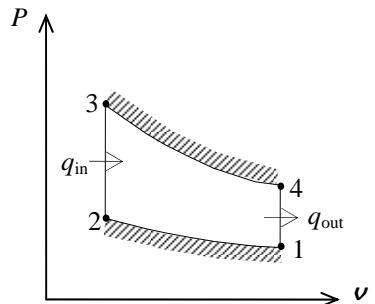

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis (a) Process 1-2 is isentropic compression:

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (300 \text{ K})(9.2)^{0.4} = 728.8 \text{ K}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (9.2) \left(\frac{728.8 \text{ K}}{300 \text{ K}} \right) (98 \text{ kPa}) = 2190 \text{ kPa}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow T_3 = \frac{P_3}{P_2} T_2 = 2T_2 = (2)(728.8) = 1457.6 \text{ K}$$

$$q_{in} = u_3 - u_2 = c_v (T_3 - T_2) = (0.718 \text{ kJ/kg}\cdot\text{K})(1457.6 - 728.8) \text{ K} = 523.3 \text{ kJ/kg}$$

(b) Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = (1457.6 \text{ K}) \left(\frac{1}{9.2} \right)^{0.4} = 600.0 \text{ K}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{out} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(600 - 300) \text{ K} = 215.4 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 523.3 - 215.4 = 307.9 \text{ kJ/kg}$$

$$(c) \quad \eta_{th} = \frac{w_{net}}{q_{in}} = \frac{307.9 \text{ kJ/kg}}{523.3 \text{ kJ/kg}} = 58.8\%$$

$$(d) \quad \nu_{max} = \nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})}{98 \text{ kPa}} = 0.879 \text{ m}^3/\text{kg}$$

$$\nu_{min} = \nu_2 = \frac{\nu_{max}}{r}$$

$$\text{MEP} = \frac{w_{net}}{\nu_1 - \nu_2} = \frac{w_{net}}{\nu_1(1 - 1/r)} = \frac{307.9 \text{ kJ/kg}}{(0.879 \text{ m}^3/\text{kg})(1 - 1/9.2)} \left(\frac{1 \text{ kPa}\cdot\text{m}^3}{1 \text{ kJ}} \right) = 393 \text{ kPa}$$

9-171E An ideal dual cycle with air as the working fluid with a compression ratio of 12 is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm.R}$, $c_v = 0.171 \text{ Btu/lbm.R}$, and $k = 1.4$ (Table A-2E).

Analysis The mass of air is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(14.7 \text{ psia})(98/1728 \text{ ft}^3)}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(580 \text{ R})} = 0.003881 \text{ lbm}$$

Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (580 \text{ R})(14)^{0.4} = 1667 \text{ R}$$

Process 2-x: $v = \text{constant}$ heat addition,

$$\begin{aligned} Q_{2-x,\text{in}} &= m(u_x - u_2) = mc_v(T_x - T_2) \\ 0.6 \text{ Btu} &= (0.003881 \text{ lbm})(0.171 \text{ Btu/lbm.R})(T_x - 1667) \text{ R} \longrightarrow T_x = 2571 \text{ R} \end{aligned}$$

Process x-3: $P = \text{constant}$ heat addition.

$$\begin{aligned} Q_{x-3,\text{in}} &= m(h_3 - h_x) = mc_p(T_3 - T_x) \\ 1.1 \text{ Btu} &= (0.003881 \text{ lbm})(0.240 \text{ Btu/lbm.R})(T_3 - 2571) \text{ R} \longrightarrow T_3 = 3752 \text{ R} \end{aligned}$$

$$\frac{P_3 V_3}{T_3} = \frac{P_x V_x}{T_x} \longrightarrow r_c = \frac{V_3}{V_x} = \frac{T_3}{T_x} = \frac{3752 \text{ R}}{2571 \text{ R}} = 1.459$$

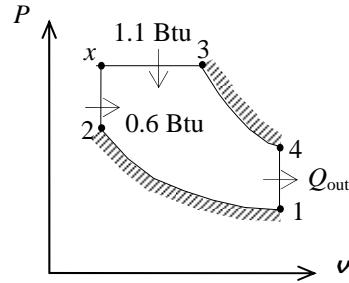

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = T_3 \left(\frac{1.459 V_1}{V_4} \right)^{k-1} = T_3 \left(\frac{1.459}{r} \right)^{k-1} = (3752 \text{ R}) \left(\frac{1.459}{14} \right)^{0.4} = 1519 \text{ R}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$\begin{aligned} Q_{\text{out}} &= m(u_4 - u_1) = mc_v(T_4 - T_1) \\ &= (0.003881 \text{ lbm})(0.171 \text{ Btu/lbm.R})(1519 - 580) \text{ R} = 0.6229 \text{ Btu} \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}} = 1 - \frac{0.6229 \text{ Btu}}{1.7 \text{ Btu}} = 0.6336 = \mathbf{63.4\%}$$

9-172 An ideal Stirling cycle with air as the working fluid is considered. The maximum pressure in the cycle and the net work output are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) The entropy change during process 1-2 is

$$s_2 - s_1 = \frac{q_{12}}{T_H} = \frac{900 \text{ kJ/kg}}{1800 \text{ K}} = 0.5 \text{ kJ/kg}\cdot\text{K}$$

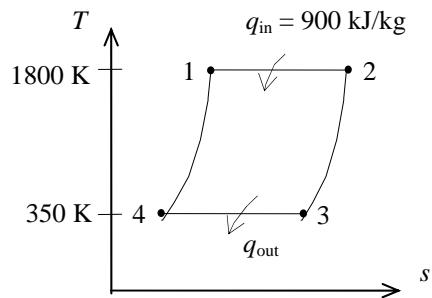

and

$$s_2 - s_1 = c_v \ln \frac{T_2}{T_1} + R \ln \frac{\nu_2}{\nu_1} \longrightarrow 0.5 \text{ kJ/kg}\cdot\text{K} = (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{\nu_2}{\nu_1} \longrightarrow \frac{\nu_2}{\nu_1} = 5.710$$

$$\frac{P_3 \nu_3}{T_3} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_1 = P_3 \frac{\nu_3}{\nu_1} \frac{T_1}{T_3} = P_3 \frac{\nu_2}{\nu_1} \frac{T_1}{T_3} = (200 \text{ kPa})(5.710) \left(\frac{1800 \text{ K}}{350 \text{ K}} \right) = 5873 \text{ kPa}$$

(b) The net work output is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = \left(1 - \frac{T_L}{T_H} \right) q_{\text{in}} = \left(1 - \frac{350 \text{ K}}{1800 \text{ K}} \right) (900 \text{ kJ/kg}) = 725 \text{ kJ/kg}$$

9-173 A simple ideal Brayton cycle with air as the working fluid is considered. The changes in the net work output per unit mass and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis The properties at various states are

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$T_3 = 1300 \text{ K} \longrightarrow h_3 = 1395.97 \text{ kJ/kg}$$

$$P_{r_3} = 330.9$$

For $r_p = 6$,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (6)(1.386) = 8.316 \longrightarrow h_2 = 501.40 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{6}\right)(330.9) = 55.15 \longrightarrow h_4 = 855.3 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 1395.97 - 501.40 = 894.57 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 855.3 - 300.19 = 555.11 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 894.57 - 555.11 = 339.46 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{339.46 \text{ kJ/kg}}{894.57 \text{ kJ/kg}} = 37.9\%$$

For $r_p = 12$,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (12)(1.386) = 16.63 \longrightarrow h_2 = 610.6 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{12}\right)(330.9) = 27.58 \longrightarrow h_4 = 704.6 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 1395.97 - 610.60 = 785.37 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 704.6 - 300.19 = 404.41 \text{ kJ/kg}$$

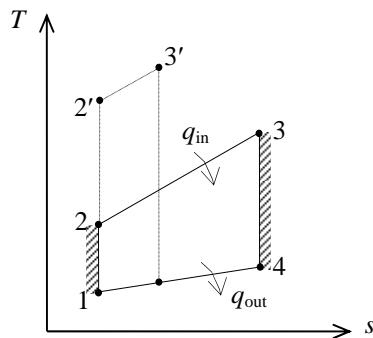

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 785.37 - 404.41 = 380.96 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{380.96 \text{ kJ/kg}}{785.37 \text{ kJ/kg}} = 48.5\%$$

Thus,

$$(a) \quad \Delta w_{\text{net}} = 380.96 - 339.46 = \mathbf{41.5 \text{ kJ/kg}} \quad (\text{increase})$$

$$(b) \quad \Delta \eta_{\text{th}} = 48.5\% - 37.9\% = \mathbf{10.6\%} \quad (\text{increase})$$

9-174 A simple ideal Brayton cycle with air as the working fluid is considered. The changes in the net work output per unit mass and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis Processes 1-2 and 3-4 are isentropic. Therefore, For $r_p = 6$,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) (6)^{0.4/1.4} = 500.6 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left(\frac{1}{6} \right)^{0.4/1.4} = 779.1 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = c_p(T_3 - T_2) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 500.6) \text{ K} = 803.4 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} q_{\text{out}} &= h_4 - h_1 = c_p(T_4 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(779.1 - 300) \text{ K} = 481.5 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 803.4 - 481.5 = 321.9 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{321.9 \text{ kJ/kg}}{803.4 \text{ kJ/kg}} = 40.1\%$$

For $r_p = 12$,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) (12)^{0.4/1.4} = 610.2 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left(\frac{1}{12} \right)^{0.4/1.4} = 639.2 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= h_3 - h_2 = c_p(T_3 - T_2) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 610.2) \text{ K} = 693.2 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} q_{\text{out}} &= h_4 - h_1 = c_p(T_4 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(639.2 - 300) \text{ K} = 340.9 \text{ kJ/kg} \end{aligned}$$

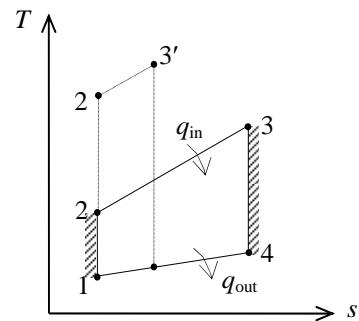

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 693.2 - 340.9 = 352.3 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{352.3 \text{ kJ/kg}}{693.2 \text{ kJ/kg}} = 50.8\%$$

Thus,

$$(a) \quad \Delta w_{\text{net}} = 352.3 - 321.9 = \mathbf{30.4 \text{ kJ/kg}} \quad (\text{increase})$$

$$(b) \quad \Delta \eta_{\text{th}} = 50.8\% - 40.1\% = \mathbf{10.7\%} \quad (\text{increase})$$

9-175 A regenerative gas-turbine engine operating with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine.

$$T_{4s} = T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) (4)^{0.4/1.4} = 445.8 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_4 = T_2 = T_1 + (T_{2s} - T_1)/\eta_C \\ = 300 + (445.8 - 300)/(0.78) \\ = 486.9 \text{ K}$$

$$T_{9s} = T_{7s} = T_6 \left(\frac{P_7}{P_6} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 942.1 \text{ K}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} = \frac{c_p(T_6 - T_7)}{c_p(T_6 - T_{7s})} \longrightarrow T_9 = T_7 = T_6 - \eta_T(T_6 - T_{7s}) \\ = 1400 - (0.86)(1400 - 942.1) \\ = 1006 \text{ K}$$

$$\varepsilon = \frac{h_5 - h_4}{h_9 - h_4} = \frac{c_p(T_5 - T_4)}{c_p(T_9 - T_4)} \longrightarrow T_5 = T_4 + \varepsilon(T_9 - T_4) \\ = 486.9 + (0.75)(1006 - 486.9) \\ = 876.4 \text{ K}$$

$$w_{C,in} = 2(h_2 - h_1) = 2c_p(T_2 - T_1) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(486.9 - 300)\text{K} = 375.7 \text{ kJ/kg}$$

$$w_{T,out} = 2(h_6 - h_7) = 2c_p(T_6 - T_7) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(1400 - 1006)\text{K} = 791.5 \text{ kJ/kg}$$

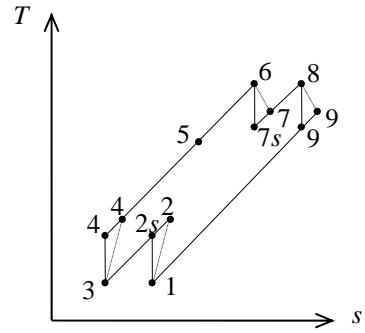

Thus,

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{375.7 \text{ kJ/kg}}{791.5 \text{ kJ/kg}} = \mathbf{0.475}$$

$$q_{in} = (h_6 - h_5) + (h_8 - h_7) = c_p[(T_6 - T_5) + (T_8 - T_7)] \\ = (1.005 \text{ kJ/kg}\cdot\text{K})[(1400 - 876.4) + (1400 - 1006)]\text{K} = 922.0 \text{ kJ/kg}$$

$$w_{net} = w_{T,out} - w_{C,in} = 791.5 - 375.7 = 415.8 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{415.8 \text{ kJ/kg}}{922.0 \text{ kJ/kg}} = 0.451 = \mathbf{45.1\%}$$

9-176 Problem 9-175 is reconsidered. The effect of the isentropic efficiencies for the compressor and turbine and regenerator effectiveness on net work done and the heat supplied to the cycle is to be investigated. Also, the *T-s* diagram for the cycle is to be plotted.

Analysis Using EES, the problem is solved as follows:

```

9-177 A regenerative gas-turbine engine operating with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Helium is an ideal gas with constant specific heats.

Properties The properties of helium at room temperature are $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine.

$$T_{4s} = T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) (4)^{0.667/1.667} = 522.4 \text{ K}$$

$$\begin{aligned} \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_4 = T_2 = T_1 + (T_{2s} - T_1)/\eta_C \\ &= 300 + (522.4 - 300)/(0.78) \\ &= 585.2 \text{ K} \end{aligned}$$

$$T_{9s} = T_{7s} = T_6 \left(\frac{P_7}{P_6} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{1}{4} \right)^{0.667/1.667} = 804.0 \text{ K}$$

$$\begin{aligned} \eta_T &= \frac{h_6 - h_7}{h_6 - h_{7s}} = \frac{c_p(T_6 - T_7)}{c_p(T_6 - T_{7s})} \longrightarrow T_9 = T_7 = T_6 - \eta_T(T_6 - T_{7s}) \\ &= 1400 - (0.86)(1400 - 804.0) \\ &= 887.4 \text{ K} \end{aligned}$$

$$\begin{aligned} \varepsilon &= \frac{h_5 - h_4}{h_9 - h_4} = \frac{c_p(T_5 - T_4)}{c_p(T_9 - T_4)} \longrightarrow T_5 = T_4 + \varepsilon(T_9 - T_4) \\ &= 585.2 + (0.75)(887.4 - 585.2) \\ &= 811.8 \text{ K} \end{aligned}$$

$$w_{C,in} = 2(h_2 - h_1) = 2c_p(T_2 - T_1) = 2(5.1926 \text{ kJ/kg}\cdot\text{K})(585.2 - 300)\text{K} = 2961 \text{ kJ/kg}$$

$$w_{T,out} = 2(h_6 - h_7) = 2c_p(T_6 - T_7) = 2(5.1926 \text{ kJ/kg}\cdot\text{K})(1400 - 887.4)\text{K} = 5323 \text{ kJ/kg}$$

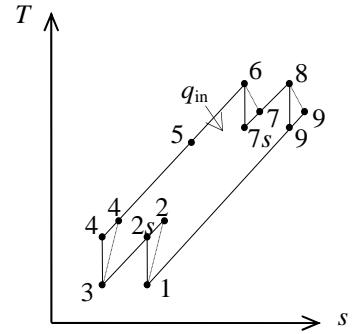

Thus,

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{2961 \text{ kJ/kg}}{5323 \text{ kJ/kg}} = \mathbf{0.556}$$

$$\begin{aligned} q_{in} &= (h_6 - h_5) + (h_8 - h_7) = c_p [(T_6 - T_5) + (T_8 - T_7)] \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K})[(1400 - 811.8) + (1400 - 887.4)]\text{K} = 5716 \text{ kJ/kg} \end{aligned}$$

$$w_{net} = w_{T,out} - w_{C,in} = 5323 - 2961 = 2362 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{2362 \text{ kJ/kg}}{5716 \text{ kJ/kg}} = 0.4133 = \mathbf{41.3\%}$$

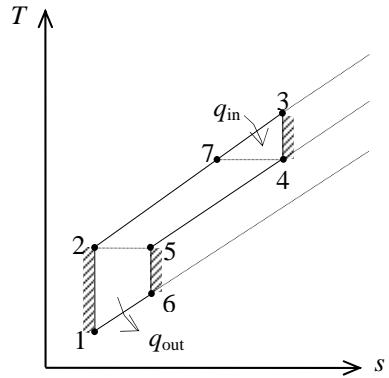

9-178 An ideal gas-turbine cycle with one stage of compression and two stages of expansion and regeneration is considered. The thermal efficiency of the cycle as a function of the compressor pressure ratio and the high-pressure turbine to compressor inlet temperature ratio is to be determined, and to be compared with the efficiency of the standard regenerative cycle.

Analysis The $T-s$ diagram of the cycle is as shown in the figure. If the overall pressure ratio of the cycle is r_p , which is the pressure ratio across the compressor, then the pressure ratio across each turbine stage in the ideal case becomes $\sqrt{r_p}$. Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$T_5 = T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k}$$

$$T_7 = T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{\sqrt{r_p}} \right)^{(k-1)/k} = T_3 r_p^{(1-k)/2k}$$

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = T_5 \left(\frac{1}{\sqrt{r_p}} \right)^{(k-1)/k} = T_2 r_p^{(1-k)/2k} = T_1 r_p^{(k-1)/k} r_p^{(1-k)/2k} = T_1 r_p^{(k-1)/2k}$$

Then,

$$q_{in} = h_3 - h_7 = c_p (T_3 - T_7) = c_p T_3 (1 - r_p^{(1-k)/2k})$$

$$q_{out} = h_6 - h_1 = c_p (T_6 - T_1) = c_p T_1 (r_p^{(k-1)/2k} - 1)$$

and thus

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{c_p T_1 (r_p^{(k-1)/2k} - 1)}{c_p T_3 (1 - r_p^{(1-k)/2k})}$$

which simplifies to

$$\eta_{th} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/2k}$$

The thermal efficiency of the single stage ideal regenerative cycle is given as

$$\eta_{th} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/k}$$

Therefore, the regenerative cycle with two stages of expansion has a higher thermal efficiency than the standard regenerative cycle with a single stage of expansion for any given value of the pressure ratio r_p .

9-179 A gas-turbine plant operates on the regenerative Brayton cycle with reheating and intercooling. The back work ratio, the net work output, the thermal efficiency, the second-law efficiency, and the exergies at the exits of the combustion chamber and the regenerator are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Optimum intercooling and reheating pressure is

$$P_2 = \sqrt{P_1 P_4} = \sqrt{(100)(1200)} = 346.4 \text{ kPa}$$

Process 1-2, 3-4: Compression

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.43 \text{ kJ/kg}$$

$$\begin{aligned} T_1 = 300 \text{ K} \\ P_1 = 100 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} s_1 &= 5.7054 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right.$$

$$\begin{aligned} P_2 = 346.4 \text{ kPa} \\ s_2 = s_1 = 5.7054 \text{ kJ/kg}\cdot\text{K} \end{aligned} \quad \left. \begin{aligned} h_{2s} &= 428.79 \text{ kJ/kg} \end{aligned} \right.$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.80 = \frac{428.79 - 300.43}{h_2 - 300.43} \longrightarrow h_2 = 460.88 \text{ kJ/kg}$$

$$T_3 = 350 \text{ K} \longrightarrow h_3 = 350.78 \text{ kJ/kg}$$

$$\begin{aligned} T_3 = 350 \text{ K} \\ P_3 = 346.4 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} s_3 &= 5.5040 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right.$$

$$\begin{aligned} P_4 = 1200 \text{ kPa} \\ s_4 = s_3 = 5.5040 \text{ kJ/kg}\cdot\text{K} \end{aligned} \quad \left. \begin{aligned} h_{4s} &= 500.42 \text{ kJ/kg} \end{aligned} \right.$$

$$\eta_C = \frac{h_{4s} - h_3}{h_4 - h_3} \longrightarrow 0.80 = \frac{500.42 - 350.78}{h_4 - 350.78} \longrightarrow h_4 = 537.83 \text{ kJ/kg}$$

Process 6-7, 8-9: Expansion

$$T_6 = 1400 \text{ K} \longrightarrow h_6 = 1514.9 \text{ kJ/kg}$$

$$\begin{aligned} T_6 = 1400 \text{ K} \\ P_6 = 1200 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} s_6 &= 6.6514 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right.$$

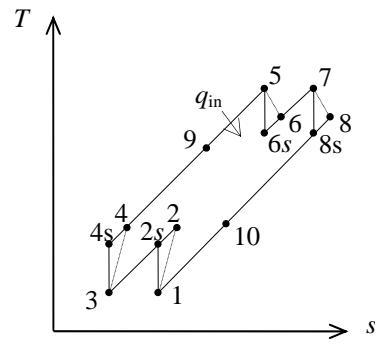

$$\begin{aligned} P_7 = 346.4 \text{ kPa} \\ s_7 = s_6 = 6.6514 \text{ kJ/kg}\cdot\text{K} \end{aligned} \quad \left. \begin{aligned} h_{7s} &= 1083.9 \text{ kJ/kg} \end{aligned} \right.$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} \longrightarrow 0.80 = \frac{1514.9 - h_7}{1514.9 - 1083.9} \longrightarrow h_7 = 1170.1 \text{ kJ/kg}$$

$$T_8 = 1300 \text{ K} \longrightarrow h_8 = 1395.6 \text{ kJ/kg}$$

$$\begin{aligned} T_8 = 1300 \text{ K} \\ P_8 = 346.4 \text{ kPa} \end{aligned} \quad \left. \begin{aligned} s_8 &= 6.9196 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right.$$

$$\begin{aligned} P_9 = 100 \text{ kPa} \\ s_9 = s_8 = 6.9196 \text{ kJ/kg}\cdot\text{K} \end{aligned} \quad \left. \begin{aligned} h_{9s} &= 996.00 \text{ kJ/kg} \end{aligned} \right.$$

$$\eta_T = \frac{h_8 - h_9}{h_8 - h_{9_s}} \longrightarrow 0.80 = \frac{1395.6 - h_9}{1395.6 - 996.00} \longrightarrow h_9 = 1075.9 \text{ kJ/kg}$$

Cycle analysis:

$$w_{C,in} = h_2 - h_1 + h_4 - h_3 = 460.88 - 300.43 + 537.83 - 350.78 = 347.50 \text{ kJ/kg}$$

$$w_{T,out} = h_6 - h_7 + h_8 - h_9 = 1514.9 - 1170.1 + 1395.6 - 1075.9 = 664.50 \text{ kJ/kg}$$

$$r_{bw} = \frac{w_{C,in}}{w_{T,out}} = \frac{347.50}{664.50} = \mathbf{0.523}$$

$$w_{net} = w_{T,out} - w_{C,in} = 664.50 - 347.50 = \mathbf{317.0 \text{ kJ/kg}}$$

Regenerator analysis:

$$\varepsilon_{regen} = \frac{h_9 - h_{10}}{h_9 - h_4} \longrightarrow 0.75 = \frac{1075.9 - h_{10}}{1075.9 - 537.83} \longrightarrow h_{10} = 672.36 \text{ kJ/kg}$$

$$\left. \begin{array}{l} h_{10} = 672.36 \text{ K} \\ P_{10} = 100 \text{ kPa} \end{array} \right\} s_{10} = 6.5157 \text{ kJ/kg} \cdot \text{K}$$

$$q_{regen} = h_9 - h_{10} = h_5 - h_4 \longrightarrow 1075.9 - 672.36 = h_5 - 537.83 \longrightarrow h_5 = 941.40 \text{ kJ/kg}$$

$$(b) \quad q_{in} = h_6 - h_5 = 1514.9 - 941.40 = 573.54 \text{ kJ/kg}$$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{317.0}{573.54} = \mathbf{0.553}$$

(c) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). The maximum temperature for the cycle can be taken to be the turbine inlet temperature. That is,

$$\eta_{max} = 1 - \frac{T_1}{T_6} = 1 - \frac{300 \text{ K}}{1400 \text{ K}} = 0.786$$

and

$$\eta_{II} = \frac{\eta_{th}}{\eta_{max}} = \frac{0.553}{0.786} = \mathbf{0.704}$$

(d) The exergies at the combustion chamber exit and the regenerator exit are

$$\begin{aligned} x_6 &= h_6 - h_0 - T_0(s_6 - s_0) \\ &= (1514.9 - 300.43) \text{ kJ/kg} - (300 \text{ K})(6.6514 - 5.7054) \text{ kJ/kg.K} \\ &= \mathbf{930.7 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{10} &= h_{10} - h_0 - T_0(s_{10} - s_0) \\ &= (672.36 - 300.43) \text{ kJ/kg} - (300 \text{ K})(6.5157 - 5.7054) \text{ kJ/kg.K} \\ &= \mathbf{128.8 \text{ kJ/kg}} \end{aligned}$$

9-180 The thermal efficiency of a two-stage gas turbine with regeneration, reheating and intercooling to that of a three-stage gas turbine is to be compared.

Assumptions 1 The air standard assumptions are applicable. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis

Two Stages:

The pressure ratio across each stage is

$$r_p = \sqrt{16} = 4$$

The temperatures at the end of compression and expansion are

$$T_c = T_{\min} r_p^{(k-1)/k} = (283 \text{ K})(4)^{0.4/1.4} = 420.5 \text{ K}$$

$$T_e = T_{\max} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (873 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 587.5 \text{ K}$$

The heat input and heat output are

$$q_{\text{in}} = 2c_p(T_{\max} - T_e) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(873 - 587.5) \text{ K} = 573.9 \text{ kJ/kg}$$

$$q_{\text{out}} = 2c_p(T_c - T_{\min}) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(420.5 - 283) \text{ K} = 276.4 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{276.4}{573.9} = \mathbf{0.518}$$

Three Stages:

The pressure ratio across each stage is

$$r_p = 16^{1/3} = 2.520$$

The temperatures at the end of compression and expansion are

$$T_c = T_{\min} r_p^{(k-1)/k} = (283 \text{ K})(2.520)^{0.4/1.4} = 368.5 \text{ K}$$

$$T_e = T_{\max} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (873 \text{ K}) \left(\frac{1}{2.520} \right)^{0.4/1.4} = 670.4 \text{ K}$$

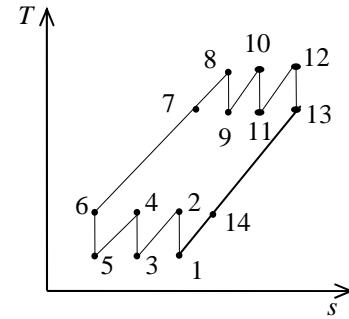

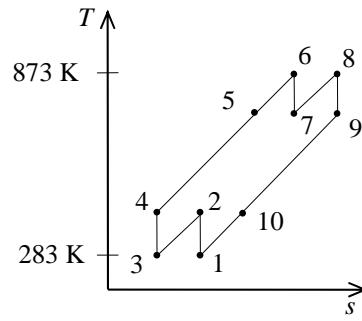

The heat input and heat output are

$$q_{\text{in}} = 3c_p(T_{\max} - T_e) = 3(1.005 \text{ kJ/kg}\cdot\text{K})(873 - 670.4) \text{ K} = 610.8 \text{ kJ/kg}$$

$$q_{\text{out}} = 3c_p(T_c - T_{\min}) = 3(1.005 \text{ kJ/kg}\cdot\text{K})(368.5 - 283) \text{ K} = 257.8 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{257.8}{610.8} = \mathbf{0.578}$$

9-181E A pure jet engine operating on an ideal cycle is considered. The thrust force produced per unit mass flow rate is to be determined.

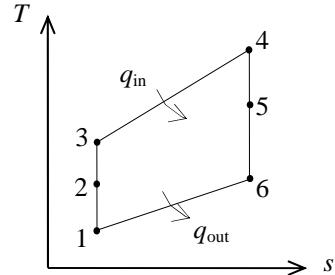

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ (Table A-1E), $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 1200 \text{ ft/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \approx 0$).

Diffuser:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta\dot{E}_{\text{system}} \xrightarrow{\text{d}0 \text{ (steady)}} \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_1 + V_1^2/2 &= h_2 + V_2^2/2 \xrightarrow{0} h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \\ 0 &= c_p(T_2 - T_1) - V_1^2/2 \\ T_2 &= T_1 + \frac{V_1^2}{2c_p} = 490 \text{ R} + \frac{(1200 \text{ ft/s})^2}{(2)(0.24 \text{ Btu/lbm}\cdot\text{R})} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 609.8 \text{ R} \\ P_2 &= P_1 \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = (10 \text{ psia}) \left(\frac{609.8 \text{ R}}{490 \text{ R}} \right)^{1.4/0.4} = 21.5 \text{ psia}\end{aligned}$$

Compressor:

$$\begin{aligned}P_3 &= P_4 = (r_p)(P_2) = (9)(21.5 \text{ psia}) = 193.5 \text{ psia} \\ T_3 &= T_2 \left(\frac{P_3}{P_2} \right)^{(k-1)/k} = (609.8 \text{ R})(9)^{0.4/1.4} = 1142.4 \text{ R}\end{aligned}$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \xrightarrow{} h_3 - h_2 = h_4 - h_5 \xrightarrow{} c_p(T_3 - T_2) = c_p(T_4 - T_5)$$

$$\text{or } T_5 = T_4 - T_3 + T_2 = 1160 - 1142.4 + 609.8 = 627.4 \text{ R}$$

Nozzle:

$$T_6 = T_4 \left(\frac{P_6}{P_4} \right)^{(k-1)/k} = (1160 \text{ R}) \left(\frac{10 \text{ psia}}{193.5 \text{ psia}} \right)^{0.4/1.4} = 497.5 \text{ R}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta\dot{E}_{\text{system}} \xrightarrow{\text{d}0 \text{ (steady)}} \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_5 + V_5^2/2 = h_6 + V_6^2/2$$

$$0 = h_6 - h_5 + \frac{V_6^2 - V_5^2}{2} \xrightarrow{0 = c_p(T_6 - T_5) + V_6^2/2}$$

$$\text{or, } V_6 = V_{\text{exit}} = \sqrt{(2)(0.24 \text{ Btu/lbm}\cdot\text{R})(627.4 - 497.5)\text{R}} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) = 1249 \text{ ft/s}$$

The specific impulse is then

$$\frac{F}{\dot{m}} = V_{\text{exit}} - V_{\text{inlet}} = 1249 - 1200 = \mathbf{49 \text{ m/s}}$$

9-182 The electricity and the process heat requirements of a manufacturing facility are to be met by a cogeneration plant consisting of a gas-turbine and a heat exchanger for steam production. The mass flow rate of the air in the cycle, the back work ratio, the thermal efficiency, the rate at which steam is produced in the heat exchanger, and the utilization efficiency of the cogeneration plant are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) For this problem, we use the properties of air from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Compression

$$T_1 = 20^\circ\text{C} \longrightarrow h_1 = 293.5 \text{ kJ/kg}$$

$$\begin{aligned} T_1 = 20^\circ\text{C} \\ P_1 = 100 \text{ kPa} \end{aligned} \left. \begin{aligned} s_1 &= 5.682 \text{ kJ/kg} \cdot \text{K} \\ s_2 &= s_1 = 5.682 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\}$$

$$\begin{aligned} P_2 = 1000 \text{ kPa} \\ s_2 = s_1 = 5.682 \text{ kJ/kg} \cdot \text{K} \end{aligned} \left. \begin{aligned} h_{2s} &= 567.2 \text{ kJ/kg} \\ h_2 &= h_{2s} \end{aligned} \right\}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.86 = \frac{567.2 - 293.5}{h_2 - 293.5} \longrightarrow h_2 = 611.8 \text{ kJ/kg}$$

Process 3-4: Expansion

$$T_4 = 450^\circ\text{C} \longrightarrow h_4 = 738.5 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.88 = \frac{h_3 - 738.5}{h_3 - h_{4s}}$$

We cannot find the enthalpy at state 3 directly. However, using the following lines in EES together with the isentropic efficiency relation, we find $h_3 = 1262 \text{ kJ/kg}$, $T_3 = 913.2^\circ\text{C}$, $s_3 = 6.507 \text{ kJ/kg} \cdot \text{K}$. The solution by hand would require a trial-error approach.

`h_3=enthalpy(Air, T=T_3)`

`s_3=entropy(Air, T=T_3, P=P_2)`

`h_4s=enthalpy(Air, P=P_1, s=s_3)`

Also,

$$T_5 = 325^\circ\text{C} \longrightarrow h_5 = 605.4 \text{ kJ/kg}$$

The inlet water is compressed liquid at 15°C and at the saturation pressure of steam at 200°C (1555 kPa). This is not available in the tables but we can obtain it in EES. The alternative is to use saturated liquid enthalpy at the given temperature.

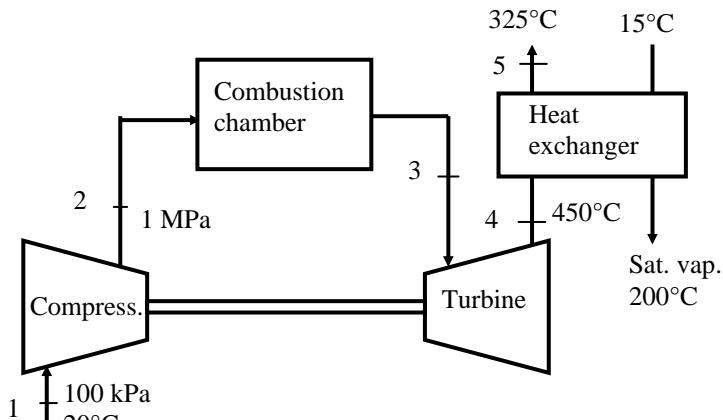

$$\begin{aligned} T_{w1} = 15^\circ\text{C} \\ P_1 = 1555 \text{ kPa} \end{aligned} \left. \begin{aligned} h_{w1} &= 64.47 \text{ kJ/kg} \\ x_2 &= 1 \end{aligned} \right\}$$

$$\begin{aligned} T_{w2} = 200^\circ\text{C} \\ x_2 = 1 \end{aligned} \left. \begin{aligned} h_{w2} &= 2792 \text{ kJ/kg} \\ w_{C,in} &= h_2 - h_1 = 611.8 - 293.5 = 318.2 \text{ kJ/kg} \\ w_{T,out} &= h_3 - h_4 = 1262 - 738.5 = 523.4 \text{ kJ/kg} \end{aligned} \right\}$$

The net work output is

$$w_{C,in} = h_2 - h_1 = 611.8 - 293.5 = 318.2 \text{ kJ/kg}$$

$$w_{T,out} = h_3 - h_4 = 1262 - 738.5 = 523.4 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 523.4 - 318.2 = 205.2 \text{ kJ/kg}$$

The mass flow rate of air is

$$\dot{m}_a = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{1500 \text{ kJ/s}}{205.2 \text{ kJ/kg}} = \mathbf{7.311 \text{ kg/s}}$$

(b) The back work ratio is

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{318.2}{523.4} = \mathbf{0.608}$$

The rate of heat input and the thermal efficiency are

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_3 - h_2) = (7.311 \text{ kg/s})(1262 - 611.8) \text{ kJ/kg} = 4753 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1500 \text{ kW}}{4753 \text{ kW}} = 0.3156 = \mathbf{31.6\%}$$

(c) An energy balance on the heat exchanger gives

$$\begin{aligned} \dot{m}_a (h_4 - h_5) &= \dot{m}_w (h_{w2} - h_{w1}) \\ (7.311 \text{ kg/s})(738.5 - 605.4) \text{ kJ/kg} &= \dot{m}_w (2792 - 64.47) \text{ kJ/kg} \longrightarrow \dot{m}_w = \mathbf{0.3569 \text{ kg/s}} \end{aligned}$$

(d) The heat supplied to the water in the heat exchanger (process heat) and the utilization efficiency are

$$\dot{Q}_p = \dot{m}_w (h_{w2} - h_{w1}) = (0.3569 \text{ kg/s})(2792 - 64.47) \text{ kJ/kg} = 973.5 \text{ kW}$$

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_p}{\dot{Q}_{\text{in}}} = \frac{1500 + 973.5}{4753 \text{ kW}} = 0.5204 = \mathbf{52.0\%}$$

9-183 A turbojet aircraft flying is considered. The pressure of the gases at the turbine exit, the mass flow rate of the air through the compressor, the velocity of the gases at the nozzle exit, the propulsive power, and the propulsive efficiency of the cycle are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

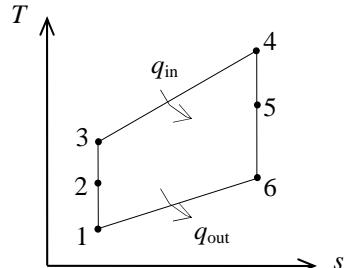

Diffuser, Process 1-2:

$$T_1 = -35^\circ\text{C} \longrightarrow h_1 = 238.23 \text{ kJ/kg}$$

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2}$$

$$(238.23 \text{ kJ/kg}) + \frac{(900/3.6 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = h_2 + \frac{(15 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \longrightarrow h_2 = 269.37 \text{ kJ/kg}$$

$$\begin{cases} h_2 = 269.37 \text{ kJ/kg} \\ P_2 = 50 \text{ kPa} \end{cases} \quad \begin{cases} s_2 = 5.7951 \text{ kJ/kg}\cdot\text{K} \end{cases}$$

Compressor, Process 2-3:

$$\begin{cases} P_3 = 450 \text{ kPa} \\ s_3 = s_2 = 5.7951 \text{ kJ/kg}\cdot\text{K} \end{cases} \quad \begin{cases} h_{3s} = 505.19 \text{ kJ/kg} \end{cases}$$

$$\eta_C = \frac{h_{3s} - h_2}{h_3 - h_2} \longrightarrow 0.83 = \frac{505.19 - 269.37}{h_3 - 269.37} \longrightarrow h_3 = 553.50 \text{ kJ/kg}$$

Turbine, Process 3-4:

$$T_4 = 950^\circ\text{C} \longrightarrow h_4 = 1304.8 \text{ kJ/kg}$$

$$h_3 - h_2 = h_4 - h_5 \longrightarrow 553.50 - 269.37 = 1304.8 - h_5 \longrightarrow h_5 = 1020.6 \text{ kJ/kg}$$

where the mass flow rates through the compressor and the turbine are assumed equal.

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow 0.83 = \frac{1304.8 - 1020.6}{1304.8 - h_{5s}} \longrightarrow h_{5s} = 962.45 \text{ kJ/kg}$$

$$\begin{cases} T_4 = 950^\circ\text{C} \\ P_4 = 450 \text{ kPa} \end{cases} \quad \begin{cases} s_4 = 6.7725 \text{ kJ/kg}\cdot\text{K} \end{cases}$$

$$\begin{cases} h_{5s} = 962.45 \text{ kJ/kg} \\ s_5 = s_4 = 6.7725 \text{ kJ/kg}\cdot\text{K} \end{cases} \quad \begin{cases} P_5 = 147.4 \text{ kPa} \end{cases}$$

(b) The mass flow rate of the air through the compressor is

$$\dot{m} = \frac{\dot{W}_C}{h_3 - h_2} = \frac{500 \text{ kJ/s}}{(553.50 - 269.37) \text{ kJ/kg}} = 1.760 \text{ kg/s}$$

(c) *Nozzle, Process 5-6:*

$$\begin{cases} h_5 = 1020.6 \text{ kJ/kg} \\ P_5 = 147.4 \text{ kPa} \end{cases} \quad \begin{cases} s_5 = 6.8336 \text{ kJ/kg}\cdot\text{K} \end{cases}$$

$$\left. \begin{array}{l} P_6 = 40 \text{ kPa} \\ s_6 = s_5 = 6.8336 \text{ kJ/kg.K} \end{array} \right\} h_{6s} = 709.66 \text{ kJ/kg}$$

$$\eta_N = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow 0.83 = \frac{1020.6 - h_6}{1020.6 - 709.66} \longrightarrow h_6 = 762.52 \text{ kJ/kg}$$

$$h_5 + \frac{V_5^2}{2} = h_6 + \frac{V_6^2}{2}$$

$$(1020.6 \text{ kJ/kg}) + 0 = 762.52 \text{ kJ/kg} + \frac{V_6^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \longrightarrow V_6 = \mathbf{718.5 \text{ m/s}}$$

where the velocity at nozzle inlet is assumed zero.

(d) The propulsive power and the propulsive efficiency are

$$\dot{W}_p = \dot{m}(V_6 - V_1)V_1 = (1.76 \text{ kg/s})(718.5 \text{ m/s} - 250 \text{ m/s})(250 \text{ m/s}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{206.1 \text{ kW}}$$

$$\dot{Q}_{in} = \dot{m}(h_4 - h_3) = (1.76 \text{ kg/s})(1304.8 - 553.50) \text{ kJ/kg} = 1322 \text{ kW}$$

$$\eta_p = \frac{\dot{W}_p}{\dot{Q}_{in}} = \frac{206.1 \text{ kW}}{1322 \text{ kW}} = \mathbf{0.156}$$

9-184 The three processes of an air standard cycle are described. The cycle is to be shown on the $P-v$ and $T-s$ diagrams, and the expressions for back work ratio and the thermal efficiency are to be obtained.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis (a) The $P-v$ and $T-s$ diagrams for this cycle are as shown.

(b) The work of compression is found by the first law for process 1-2:

$$q_{1-2} - w_{1-2} = \Delta u_{1-2}$$

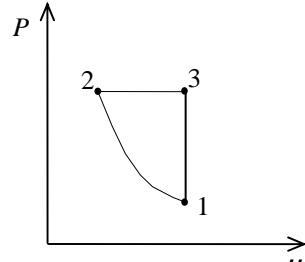

$q_{1-2} = 0$ (isentropic process)

$$w_{1-2} = -\Delta u_{1-2} = -C_v(T_2 - T_1)$$

$$w_{comp} = -w_{1-2} = C_v(T_2 - T_1)$$

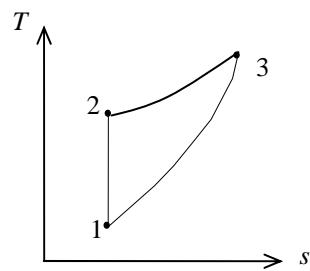

The expansion work is found by

$$w_{exp} = w_{2-3} = \int_2^3 P dv = P(v_3 - v_2) = R(T_3 - T_2)$$

The back work ratio is

$$\frac{w_{comp}}{w_{exp}} = \frac{C_v(T_3 - T_1)}{R(T_3 - T_2)} = \frac{C_v}{R} \frac{T_1}{T_2} \frac{(T_3/T_1 - 1)}{(T_3/T_2 - 1)}$$

Process 1-2 is isentropic; therefore,

$$\frac{T_1}{T_2} = \left(\frac{V_2}{V_1} \right)^{k-1} = \frac{1}{r^{k-1}} \quad \text{and} \quad \frac{P_2}{P_1} = \left(\frac{V_1}{V_2} \right)^k = r^k$$

Process 2-3 is constant pressure; therefore,

$$\frac{P_3 V_3}{T_3} = \frac{P_2 V_2}{T_2} \Rightarrow \frac{T_3}{T_2} = \frac{V_3}{V_2} = \frac{V_1}{V_2} = r$$

Process 3-1 is constant volume; therefore,

$$\frac{P_3 V_3}{T_3} = \frac{P_1 V_1}{T_1} \Rightarrow \frac{T_3}{T_1} = \frac{P_3}{P_1} = \frac{P_2}{P_1} = r^k$$

The back work ratio becomes ($C_v=R/(k-1)$)

$$\frac{w_{comp}}{w_{exp}} = \frac{1}{k-1} \frac{1}{r^{k-1}} \frac{r^{k-1} - 1}{r - 1}$$

(c) Apply first law to the closed system for processes 2-3 and 3-1 to show:

$$q_{in} = C_p(T_3 - T_2)$$

$$q_{out} = C_v(T_3 - T_1)$$

The cycle thermal efficiency is given by

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{C_v(T_3 - T_1)}{C_p(T_3 - T_2)} = 1 - \frac{1}{k} \frac{T_1(T_3/T_1 - 1)}{T_2(T_3/T_2 - 1)}$$

The efficiency becomes

$$\eta_{th} = 1 - \frac{1}{k} \frac{1}{r^{k-1}} \frac{r^k - 1}{r - 1}$$

(d) Determine the value of the back work ratio and efficiency as r goes to unity.

$$\begin{aligned}\frac{w_{comp}}{w_{exp}} &= \frac{1}{k-1} \frac{1}{r^{k-1}} \frac{r^{k-1} - 1}{r - 1} \\ \lim_{r \rightarrow 1} \frac{w_{comp}}{w_{exp}} &= \frac{1}{k-1} \left\{ \lim_{r \rightarrow 1} \frac{1}{r^{k-1}} \frac{r^{k-1} - 1}{r - 1} \right\} = \frac{1}{k-1} \left\{ \lim_{r \rightarrow 1} \frac{r^{k-1} - 1}{r^k - r^{k-1}} \right\} = \frac{1}{k-1} \left\{ \lim_{r \rightarrow 1} \frac{(k-1)r^{k-2}}{kr^{k-1} - (k-1)r^{k-2}} \right\} \\ \lim_{r \rightarrow 1} \frac{w_{comp}}{w_{exp}} &= \frac{1}{k-1} \left\{ \frac{k-1}{k-k+1} \right\} = \frac{1}{k-1} \left\{ \frac{k-1}{1} \right\} = 1 \\ \eta_{th} &= 1 - \frac{1}{k} \frac{1}{r^{k-1}} \frac{r^k - 1}{r - 1} \\ \lim_{r \rightarrow 1} \eta_{th} &= 1 - \frac{1}{k} \left\{ \lim_{r \rightarrow 1} \frac{1}{r^{k-1}} \frac{r^k - 1}{r - 1} \right\} = 1 - \frac{1}{k} \left\{ \lim_{r \rightarrow 1} \frac{r^k - 1}{r^k - r^{k-1}} \right\} = 1 - \frac{1}{k} \left\{ \lim_{r \rightarrow 1} \frac{kr^{k-1}}{kr^{k-1} - (k-1)r^{k-2}} \right\} \\ \lim_{r \rightarrow 1} \eta_{th} &= 1 - \frac{1}{k} \left\{ \frac{k}{k-k+1} \right\} = 1 - \frac{1}{k} \left\{ \frac{k}{1} \right\} = 0\end{aligned}$$

These results show that if there is no compression (i.e. $r = 1$), there can be no expansion and no net work will be done even though heat may be added to the system.

9-185 The three processes of an air standard cycle are described. The cycle is to be shown on the $P-v$ and $T-s$ diagrams, and the expressions for back work ratio and the thermal efficiency are to be obtained.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis (a) The $P-v$ and $T-s$ diagrams for this cycle are as shown.

(b) The work of expansion is found by the first law for process 2-3:

$$q_{2-3} - w_{2-3} = \Delta u_{2-3}$$

$q_{2-3} = 0$ (isentropic process)

$$w_{2-3} = -\Delta u_{2-3} = -C_v(T_3 - T_2)$$

$$w_{\text{exp}} = w_{2-3} = C_v(T_2 - T_3)$$

The compression work is found by

$$w_{\text{comp}} = -w_{3-1} = -\int_3^1 P dv = -P(v_1 - v_3) = R(T_3 - T_1)$$

The back work ratio is

$$\frac{w_{\text{comp}}}{w_{\text{exp}}} = \frac{C_v(T_3 - T_1)}{R(T_2 - T_3)} = \frac{C_v}{R} \frac{T_3(1 - T_1/T_3)}{T_3(T_2/T_3 - 1)} = \frac{C_v}{R} \frac{(1 - T_1/T_3)}{(T_2/T_3 - 1)}$$

Process 3-1 is constant pressure; therefore,

$$\frac{P_3 V_3}{T_3} = \frac{P_1 V_1}{T_1} \Rightarrow \frac{T_1}{T_3} = \frac{V_1}{V_3} = \frac{V_2}{V_3} = \frac{1}{r}$$

Process 2-3 is isentropic; therefore,

$$\frac{T_2}{T_3} = \left(\frac{V_2}{V_3} \right)^{k-1} = r^{k-1} \quad \text{and} \quad \frac{P_2}{P_3} = \left(\frac{V_3}{V_2} \right)^k = r^k$$

The back work ratio becomes ($C_v = R/(k-1)$)

$$\frac{w_{\text{comp}}}{w_{\text{exp}}} = (k-1) \frac{1 - \frac{1}{r}}{r^{k-1} - 1} = \frac{k-1}{r} \frac{r-1}{r^{k-1} - 1}$$

(c) Apply first law to the closed system for processes 1-2 and 3-1 to show:

$$q_{in} = C_v(T_2 - T_1)$$

$$q_{out} = C_p(T_3 - T_1)$$

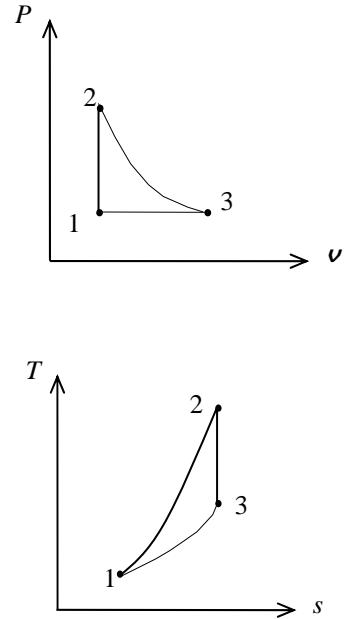

The cycle thermal efficiency is given by

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{C_p(T_3 - T_1)}{C_v(T_2 - T_1)} = 1 - k \frac{T_1(T_3/T_1 - 1)}{T_1(T_2/T_1 - 1)}$$

Process 1-2 is constant volume; therefore,

$$\frac{P_2 V_2}{T_2} = \frac{P_1 V_1}{T_1} \Rightarrow \frac{T_2}{T_1} = \frac{P_2}{P_1} = \frac{P_2}{P_3} = r^k$$

The efficiency becomes

$$\eta_{th} = 1 - k \frac{r-1}{r^k - 1}$$

(d) Determine the value of the back work ratio and efficiency as r goes to unity.

$$\begin{aligned}\frac{w_{comp}}{w_{exp}} &= (k-1) \frac{1 - \frac{1}{r}}{r^{k-1} - 1} = \frac{k-1}{r} \frac{r-1}{r^{k-1} - 1} \\ \lim_{r \rightarrow 1} \frac{w_{comp}}{w_{exp}} &= (k-1) \left\{ \lim_{r \rightarrow 1} \frac{r-1}{r^k - r} \right\} = (k-1) \left\{ \lim_{r \rightarrow 1} \frac{1}{kr^{k-1} - 1} \right\} \\ \lim_{r \rightarrow 1} \frac{w_{comp}}{w_{exp}} &= (k-1) \left\{ \frac{1}{k-1} \right\} = 1\end{aligned}$$

$$\begin{aligned}\eta_{th} &= 1 - k \frac{r-1}{r^k - 1} \\ \lim_{r \rightarrow 1} \eta_{th} &= 1 - k \left\{ \lim_{r \rightarrow 1} \frac{r-1}{r^k - 1} \right\} = 1 - k \left\{ \lim_{r \rightarrow 1} \frac{1}{kr^{k-1}} \right\} \\ \lim_{r \rightarrow 1} \eta_{th} &= 1 - k \left\{ \frac{1}{k} \right\} = 0\end{aligned}$$

These results show that if there is no compression (i.e. $r = 1$), there can be no expansion and no net work will be done even though heat may be added to the system.

9-186 The four processes of an air-standard cycle are described. The cycle is to be shown on the $P-v$ and $T-s$ diagrams; an expression for the cycle thermal efficiency is to be obtained; and the limit of the efficiency as the volume ratio during heat rejection approaches unity is to be evaluated.

Analysis (a) The $P-v$ and $T-s$ diagrams of the cycle are shown in the figures.

(b) Apply first law to the closed system for processes 2-3 and 4-1 to show:

$$q_{in} = C_v(T_3 - T_2)$$

$$q_{out} = C_p(T_4 - T_1)$$

The cycle thermal efficiency is given by

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{C_p(T_4 - T_1)}{C_v(T_3 - T_2)} = 1 - k \frac{T_1(T_4/T_1 - 1)}{T_2(T_3/T_2 - 1)}$$

$$\text{Process 1-2 is isentropic; therefore, } \frac{T_1}{T_2} = \left(\frac{V_2}{V_1} \right)^{k-1} = \frac{1}{r^{k-1}}$$

$$\text{Process 3-4 is isentropic; therefore, } \frac{T_3}{T_4} = \left(\frac{V_4}{V_3} \right)^{k-1} = r_e^{k-1}$$

Process 4-1 is constant pressure; therefore,

$$\frac{P_4 V_4}{T_4} = \frac{P_1 V_1}{T_1} \Rightarrow \frac{T_4}{T_1} = \frac{V_4}{V_1} = r_p$$

$$\frac{T_3}{T_2} = \frac{T_3}{T_4} \frac{T_4}{T_1} \frac{T_1}{T_2} = r_e^{k-1} r_p \frac{1}{r^{k-1}} = \left(\frac{r_e}{r} \right)^{k-1} r_p$$

Since process 2-3 is constant volume and $V_3 = V_2$,

$$r_e = \frac{V_4}{V_3} = \frac{V_4}{V_2} = \frac{V_4}{V_1} \frac{V_1}{V_2} = r_p r$$

$$\frac{T_3}{T_2} = \left(\frac{r_p r}{r} \right)^{k-1} r_p = r_p^k$$

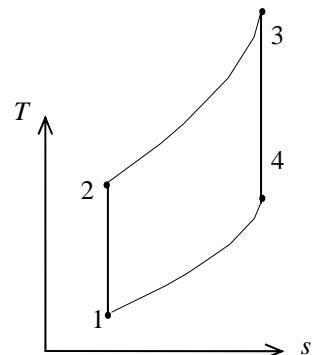

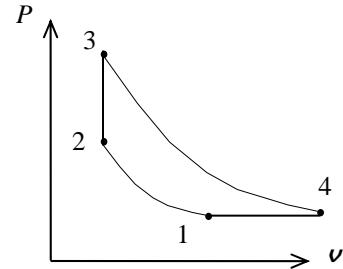

The efficiency becomes

$$\eta_{th} = 1 - k \frac{1}{r^{k-1}} \frac{r_p - 1}{r_p^k - 1}$$

(c) In the limit as r_p approaches unity, the cycle thermal efficiency becomes

$$\lim_{r_p \rightarrow 1} \eta_{th} = 1 - k \frac{1}{r^{k-1}} \left\{ \lim_{r_p \rightarrow 1} \frac{r_p - 1}{r_p^k - 1} \right\} = 1 - k \frac{1}{r^{k-1}} \left\{ \lim_{r_p \rightarrow 1} \frac{1}{k r_p^{k-1}} \right\}$$

$$\lim_{r_p \rightarrow 1} \eta_{th} = 1 - k \frac{1}{r^{k-1}} \left\{ \frac{1}{k} \right\} = 1 - \frac{1}{r^{k-1}} = \eta_{th \text{ Otto}}$$

9-187 The four processes of an air-standard cycle are described. The back work ratio and its limit as r_p goes to unity are to be determined, and the result is to be compared to the expression for the Otto cycle.

Analysis The work of compression for process 1-2 is found by the first law:

$$\begin{aligned} q_{1-2} - w_{1-2} &= \Delta u_{1-2} \\ q_{1-2} &= 0 \text{(isentropic process)} \\ w_{1-2} &= -\Delta u_{1-2} = -C_v(T_2 - T_1) \\ w_{comp,1-2} &= -w_{1-2} = C_v(T_2 - T_1) \end{aligned}$$

The work of compression for process 4-1 is found by

$$w_{comp,4-1} = -w_{4-1} = -\int_4^1 P dv = -P(v_1 - v_4) = R(T_4 - T_1)$$

The work of expansion for process 3-4 is found by the first law:

$$\begin{aligned} q_{3-4} - w_{3-4} &= \Delta u_{3-4} \\ q_{3-4} &= 0 \text{(isentropic process)} \\ w_{3-4} &= -\Delta u_{3-4} = -C_v(T_4 - T_3) \\ w_{exp,3-4} &= -w_{3-4} = C_v(T_3 - T_4) \end{aligned}$$

The back work ratio is

$$\frac{w_{comp}}{w_{exp}} = \frac{R(T_4 - T_1) + C_v(T_2 - T_1)}{C_v(T_3 - T_4)} = \frac{T_1}{T_3} \frac{\frac{R}{C_v}(T_4/T_1 - 1) + (T_2/T_1 - 1)}{(1 - T_4/T_3)}$$

Using data from the previous problem and $C_v = R/(k-1)$

$$\begin{aligned} \frac{w_{comp}}{w_{exp}} &= \frac{T_1}{T_3} \frac{(k-1)(r_p - 1) + (r^{k-1} - 1)}{\left(1 - \frac{1}{r_p^{k-1} r^{k-1}}\right)} \\ \lim_{r_p \rightarrow 1} \frac{w_{comp}}{w_{exp}} &= \frac{T_1}{T_3} \left\{ \lim_{r_p \rightarrow 1} \frac{(k-1)(r_p - 1) + (r^{k-1} - 1)}{\left(1 - \frac{1}{r_p^{k-1} r^{k-1}}\right)} \right\} = \frac{T_1}{T_3} \left\{ \frac{(k-1)(0) + (r^{k-1} - 1)}{1 - \frac{1}{r^{k-1}}} \right\} \\ \lim_{r_p \rightarrow 1} \frac{w_{comp}}{w_{exp}} &= \frac{T_1}{T_3} \left\{ \frac{r^{k-1} - 1}{1 - \frac{1}{r^{k-1}}} \right\} \end{aligned}$$

This result is the same expression for the back work ratio for the Otto cycle.

9-188 The effects of compression ratio on the net work output and the thermal efficiency of the Otto cycle for given operating conditions is to be investigated.

Analysis Using EES, the problem is solved as follows:

9-190 The effects of pressure ratio on the net work output and the thermal efficiency of a simple Brayton cycle is to be investigated assuming adiabatic efficiencies of 85 percent for both the turbine and the compressor. The pressure ratios at which the net work output and the thermal efficiency are maximum are to be determined.

Analysis Using EES, the problem is solved as follows:

```
P_ratio = 8
T[1] = 300 [K]
P[1]= 100 [kPa]
T[3] = 1800 [K]
m_dot = 1 [kg/s]
Eta_c = 80/100
Eta_t = 80/100

Fundamentals of Engineering (FE) Exam Problems

9-196 An Otto cycle with air as the working fluid has a compression ratio of 10.4. Under cold air standard conditions, the thermal efficiency of this cycle is

Answer (c) 61%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

$$\begin{aligned}r &= 10.4 \\k &= 1.4 \\Eta_{\text{Otto}} &= 1 - \frac{1}{r^{k-1}}\end{aligned}$$

"Some Wrong Solutions with Common Mistakes:"

W1_Eta = 1/r "Taking efficiency to be 1/r"

W2 Eta = 1/r^(k-1) "Using incorrect relation"

W3 Eta = 1-1/r^(k1-1); k1=1.667 "Using wrong k value"

9-197 For specified limits for the maximum and minimum temperatures, the ideal cycle with the lowest thermal efficiency is

- (a) Carnot (b) Stirling (c) Ericsson (d) Otto (e) All are the same

Answer (d) Otto

9-198 A Carnot cycle operates between the temperatures limits of 300 K and 2000 K, and produces 600 kW of net power.

- The rate of entropy change of the working fluid during the heat addition process is

(a) 0 (b) 0.2521 W/W

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

TL=300 "K"
TH=2000 "K"
Wnet=600 "kJ/s"
Wnet= (TH-TL)*DS

"Some Wrong Solutions with Common Mistakes:"

W1_DS = Wnet/TH "Using TH instead of TH-TI "

W1_DS = Wnet/TI "Using TI instead of TH-TI"
W2_DS = Wnet/TI "Using TI instead of TH-TI"

W3_DS = Wnet/(TH+TL) "Using TH+TL instead of TH-TL "

9-199 Air in an ideal Diesel cycle is compressed from 2 L to 0.13 L, and then it expands during the constant pressure heat addition process to 0.30 L. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 41% (b) 59% (c) 66% (d) 70% (e) 78%

Answer (b) 59%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V1=2 "L"
V2= 0.13 "L"
V3= 0.30 "L"
r=V1/V2
rc=V3/V2
k=1.4
Eta_Diesel=1-(1/r^(k-1))*(rc^(k-1)/k/(rc-1))
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1-(1/r1^(k-1))*(rc^k-1)/k/(rc-1); r1=V1/V3 "Wrong r value"
W2_Eta = 1-Eta_Diesel "Using incorrect relation"
W3_Eta = 1-(1/r^(k1-1))*(rc^(k1-1)/k1/(rc-1); k1=1.667 "Using wrong k value"
W4_Eta = 1-1/r^(k-1) "Using Otto cycle efficiency"
```

9-200 Helium gas in an ideal Otto cycle is compressed from 20°C and 2.5 L to 0.25 L, and its temperature increases by an additional 700°C during the heat addition process. The temperature of helium before the expansion process is

- (a) 1790°C (b) 2060°C (c) 1240°C (d) 620°C (e) 820°C

Answer (a) 1790°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.667
V1=2.5
V2=0.25
r=V1/V2
T1=20+273 "K"
T2=T1*r^(k-1)
T3=T2+700-273 "C"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T3 = T22+700-273; T22=T1*r^(k1-1); k1=1.4 "Using wrong k value"
W2_T3 = T3+273 "Using K instead of C"
W3_T3 = T1+700-273 "Disregarding temp rise during compression"
W4_T3 = T222+700-273; T222=(T1-273)*r^(k-1) "Using C for T1 instead of K"
```

9-201 In an ideal Otto cycle, air is compressed from 1.20 kg/m^3 and 2.2 L to 0.26 L, and the net work output of the cycle is 440 kJ/kg. The mean effective pressure (MEP) for this cycle is

- (a) 612 kPa (b) 599 kPa (c) 528 kPa (d) 416 kPa (e) 367 kPa

Answer (b) 599 kPa

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
rho1=1.20 "kg/m^3"
k=1.4
V1=2.2
V2=0.26
m=rho1*V1/1000 "kg"
w_net=440 "kJ/kg"
Wtotal=m*w_net
MEP=Wtotal/((V1-V2)/1000)
```

"Some Wrong Solutions with Common Mistakes:"

W1_MEPA = w_net/((V1-V2)/1000) "Disregarding mass"

W2_MEPA = Wtotal/(V1/1000) "Using V1 instead of V1-V2"

W3_MEPA = (rho1*V2/1000)*w_net/((V1-V2)/1000); "Finding mass using V2 instead of V1"

W4_MEPA = Wtotal/((V1+V2)/1000) "Adding V1 and V2 instead of subtracting"

9-202 In an ideal Brayton cycle, air is compressed from 95 kPa and 25°C to 1100 kPa. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 45% (b) 50% (c) 62% (d) 73% (e) 86%

Answer (b) 50%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=95 "kPa"
P2=1100 "kPa"
T1=25+273 "K"
rp=P2/P1
k=1.4
Eta_Brayton=1-1/rp^((k-1)/k)
```

"Some Wrong Solutions with Common Mistakes:"

W1_Eta = 1/rp "Taking efficiency to be 1/rp"

W2_Eta = 1/rp^((k-1)/k) "Using incorrect relation"

W3_Eta = 1-1/rp^((k1-1)/k1); k1=1.667 "Using wrong k value"

9-203 Consider an ideal Brayton cycle executed between the pressure limits of 1200 kPa and 100 kPa and temperature limits of 20°C and 1000°C with argon as the working fluid. The net work output of the cycle is

- (a) 68 kJ/kg (b) 93 kJ/kg (c) 158 kJ/kg (d) 186 kJ/kg (e) 310 kJ/kg

Answer (c) 158 kJ/kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=100 "kPa"
P2=1200 "kPa"
T1=20+273 "K"
T3=1000+273 "K"
rp=P2/P1
k=1.667
Cp=0.5203 "kJ/kg.K"
Cv=0.3122 "kJ/kg.K"
T2=T1*rp^((k-1)/k)
q_in=Cp*(T3-T2)
Eta_Brayton=1-1/rp^((k-1)/k)
w_net=Eta_Brayton*q_in
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_wnet = (1-1/rp^((k-1)/k))*qin1; qin1=Cv*(T3-T2) "Using Cv instead of Cp"
W2_wnet = (1-1/rp^((k-1)/k))*qin2; qin2=1.005*(T3-T2) "Using Cp of air instead of argon"
W3_wnet = (1-1/rp^((k1-1)/k1))*Cp*(T3-T22); T22=T1*rp^((k1-1)/k1); k1=1.4 "Using k of air instead of argon"
W4_wnet = (1-1/rp^((k-1)/k))*Cp*(T3-T222); T222=(T1-273)*rp^((k-1)/k) "Using C for T1 instead of K"
```

9-204 An ideal Brayton cycle has a net work output of 150 kJ/kg and a backwork ratio of 0.4. If both the turbine and the compressor had an isentropic efficiency of 85%, the net work output of the cycle would be

- (a) 74 kJ/kg (b) 95 kJ/kg (c) 109 kJ/kg (d) 128 kJ/kg (e) 177 kJ/kg

Answer (b) 95 kJ/kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
wcomp/wturb=0.4
wturb-wcomp=150 "kJ/kg"
Eff=0.85
w_net=Eff*wturb-wcomp/Eff
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_wnet = Eff*wturb-wcomp*Eff "Making a mistake in Wnet relation"
W2_wnet = (wturb-wcomp)/Eff "Using a wrong relation"
W3_wnet = wturb/eff-wcomp*Eff "Using a wrong relation"
```

9-205 In an ideal Brayton cycle, air is compressed from 100 kPa and 25°C to 1 MPa, and then heated to 927°C before entering the turbine. Under cold air standard conditions, the air temperature at the turbine exit is

- (a) 349°C (b) 426°C (c) 622°C (d) 733°C (e) 825°C

Answer (a) 349°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=100 "kPa"
P2=1000 "kPa"
T1=25+273 "K"
T3=900+273 "K"
rp=P2/P1
k=1.4
T4=T3*(1/rp)^((k-1)/k)-273
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T4 = T3/rp "Using wrong relation"
W2_T4 = (T3-273)/rp "Using wrong relation"
W3_T4 = T4+273 "Using K instead of C"
W4_T4 = T1+800-273 "Disregarding temp rise during compression"
```

9-206 In an ideal Brayton cycle with regeneration, argon gas is compressed from 100 kPa and 25°C to 400 kPa, and then heated to 1200°C before entering the turbine. The highest temperature that argon can be heated in the regenerator is

- (a) 246°C (b) 846°C (c) 689°C (d) 368°C (e) 573°C

Answer (e) 573°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.667
Cp=0.5203 "kJ/kg.K"
P1=100 "kPa"
P2=400 "kPa"
T1=25+273 "K"
T3=1200+273 "K"
"The highest temperature that argon can be heated in the regenerator is the turbine exit temperature,"
rp=P2/P1
T2=T1*rp^((k-1)/k)
T4=T3/rp^((k-1)/k)-273
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T4 = T3/rp "Using wrong relation"
W2_T4 = (T3-273)/rp^((k-1)/k) "Using C instead of K for T3"
W3_T4 = T4+273 "Using K instead of C"
W4_T4 = T2-273 "Taking compressor exit temp as the answer"
```

9-207 In an ideal Brayton cycle with regeneration, air is compressed from 80 kPa and 10°C to 400 kPa and 175°C, is heated to 450°C in the regenerator, and then further heated to 1000°C before entering the turbine. Under cold air standard conditions, the effectiveness of the regenerator is

- (a) 33% (b) 44% (c) 62% (d) 77% (e) 89%

Answer (d) 77%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.4
Cp=1.005 "kJ/kg.K"
P1=80 "kPa"
P2=400 "kPa"
T1=10+273 "K"
T2=175+273 "K"
T3=1000+273 "K"
T5=450+273 "K"
"The highest temperature that the gas can be heated in the regenerator is the turbine exit temperature,"
rp=P2/P1
T2check=T1*rp^((k-1)/k) "Checking the given value of T2. It checks."
T4=T3/rp^((k-1)/k)
Effective=(T5-T2)/(T4-T2)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_eff = (T5-T2)/(T3-T2) "Using wrong relation"
W2_eff = (T5-T2)/(T44-T2); T44=(T3-273)/rp^((k-1)/k) "Using C instead of K for T3"
W3_eff = (T5-T2)/(T444-T2); T444=T3/rp "Using wrong relation for T4"
```

9-208 Consider a gas turbine that has a pressure ratio of 6 and operates on the Brayton cycle with regeneration between the temperature limits of 20°C and 900°C. If the specific heat ratio of the working fluid is 1.3, the highest thermal efficiency this gas turbine can have is

- (a) 38% (b) 46% (c) 62% (d) 58% (e) 97%

Answer (c) 62%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.3
rp=6
T1=20+273 "K"
T3=900+273 "K"
Eta_regen=1-(T1/T3)*rp^((k-1)/k)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1-((T1-273)/(T3-273))*rp^((k-1)/k) "Using C for temperatures instead of K"
W2_Eta = (T1/T3)*rp^((k-1)/k) "Using incorrect relation"
W3_Eta = 1-(T1/T3)*rp^((k1-1)/k1); k1=1.4 "Using wrong k value (the one for air)"
```

9-209 An ideal gas turbine cycle with many stages of compression and expansion and a regenerator of 100 percent effectiveness has an overall pressure ratio of 10. Air enters every stage of compressor at 290 K, and every stage of turbine at 1200 K. The thermal efficiency of this gas-turbine cycle is

Answer (e) 76%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

k=1.4
rp=10
T1=290 "K"
T3=1200 "K"
Eff=1-T1/T3

"Some Wrong Solutions with Common Mistakes:"

W1_Eta = 100

W2_Eta = 1-1/rp^{((k-1)/k)} "Using incorrect relation"

W3_Eta = 1-(T1/T3)*rp^(k-1/k) "Using wrong relation"

W4_Eta = T1/T3 "Using wrong relation"

9-210 Air enters a turbojet engine at 320 m/s at a rate of 30 kg/s, and exits at 650 m/s relative to the aircraft. The thrust developed by the engine is

Answer (b) 10 kN

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

Vel1=320 "m/s"

Vel2=650 "m/s"

Thrust=m*(Vel2-Vel1)/1000 "kN"

m= 30 "kg/s"

"Some Wrong Solutions with Common Mistakes:"

W1_thrust = (Vel2-Vel1)/1000 "Disregarding mass flow rate"

W2_thrust = m*Vel2/1000 "Using incorrect relation"

Carnot Vapor Cycle

10-1C The Carnot cycle is not a realistic model for steam power plants because (1) limiting the heat transfer processes to two-phase systems to maintain isothermal conditions severely limits the maximum temperature that can be used in the cycle, (2) the turbine will have to handle steam with a high moisture content which causes erosion, and (3) it is not practical to design a compressor that will handle two phases.

10-2E A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the quality at the end of the heat rejection process, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We note that

$$T_H = T_{\text{sat}@250 \text{ psia}} = 401^\circ\text{F} = 861 \text{ R}$$

$$T_L = T_{\text{sat}@40 \text{ psia}} = 267.2^\circ\text{F} = 727.2 \text{ R}$$

and

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{727.2 \text{ R}}{861 \text{ R}} = 0.1553 = \mathbf{15.5\%}$$

(b) Noting that $s_4 = s_1 = s_f @ 250 \text{ psia} = 0.56784 \text{ Btu/lbm}\cdot\text{R}$,

$$x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{0.56784 - 0.3921}{1.2845} = \mathbf{0.137}$$

(c) The enthalpies before and after the heat addition process are

$$h_1 = h_f @ 250 \text{ psia} = 376.09 \text{ Btu/lbm}$$

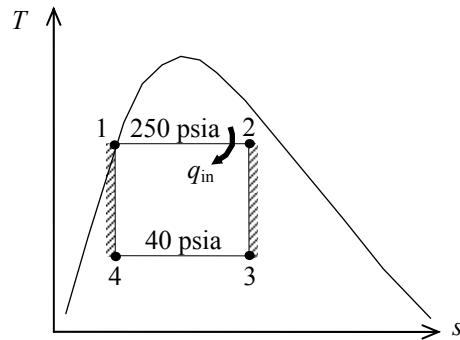

$$h_2 = h_f + x_2 h_{fg} = 376.09 + (0.95)(825.47) = 1160.3 \text{ Btu/lbm}$$

Thus,

$$q_{\text{in}} = h_2 - h_1 = 1160.3 - 376.09 = 784.2 \text{ Btu/lbm}$$

and

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.1553)(784.2 \text{ Btu/lbm}) = \mathbf{122 \text{ Btu/lbm}}$$

10-3 A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the amount of heat rejected, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = 250^\circ\text{C} = 523\text{ K}$ and $T_L = T_{\text{sat}} @ 20\text{ kPa} = 60.06^\circ\text{C} = 333.1\text{ K}$, the thermal efficiency becomes

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{333.1\text{ K}}{523\text{ K}} = 0.3632 = \mathbf{36.3\%}$$

(b) The heat supplied during this cycle is simply the enthalpy of vaporization,

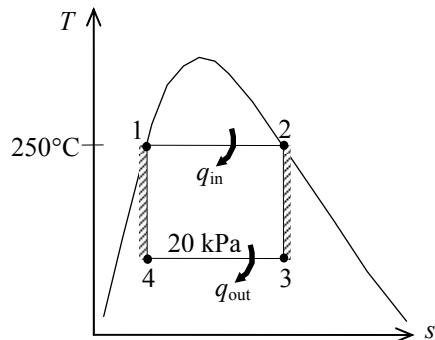

$$q_{\text{in}} = h_{fg} @ 250^\circ\text{C} = 1715.3\text{ kJ/kg}$$

Thus,

$$q_{\text{out}} = q_L = \frac{T_L}{T_H} q_{\text{in}} = \left(\frac{333.1\text{ K}}{523\text{ K}} \right) (1715.3\text{ kJ/kg}) = \mathbf{1092.3\text{ kJ/kg}}$$

(c) The net work output of this cycle is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.3632)(1715.3\text{ kJ/kg}) = \mathbf{623.0\text{ kJ/kg}}$$

10-4 A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the amount of heat rejected, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = 250^\circ\text{C} = 523\text{ K}$ and $T_L = T_{\text{sat}} @ 10\text{ kPa} = 45.81^\circ\text{C} = 318.8\text{ K}$, the thermal efficiency becomes

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{318.8\text{ K}}{523\text{ K}} = \mathbf{39.04\%}$$

(b) The heat supplied during this cycle is simply the enthalpy of vaporization,

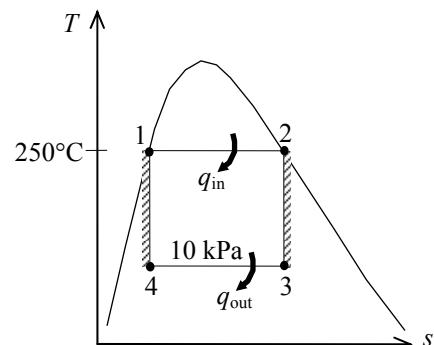

$$q_{\text{in}} = h_{fg} @ 250^\circ\text{C} = 1715.3\text{ kJ/kg}$$

Thus,

$$q_{\text{out}} = q_L = \frac{T_L}{T_H} q_{\text{in}} = \left(\frac{318.8\text{ K}}{523\text{ K}} \right) (1715.3\text{ kJ/kg}) = \mathbf{1045.6\text{ kJ/kg}}$$

(c) The net work output of this cycle is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.3904)(1715.3\text{ kJ/kg}) = \mathbf{669.7\text{ kJ/kg}}$$

10-5 A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the pressure at the turbine inlet, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The thermal efficiency is determined from

$$\eta_{\text{th},C} = 1 - \frac{T_L}{T_H} = 1 - \frac{60 + 273 \text{ K}}{350 + 273 \text{ K}} = \mathbf{46.5\%}$$

(b) Note that

$$\begin{aligned}s_2 &= s_3 = s_f + x_3 s_{fg} \\&= 0.8313 + 0.891 \times 7.0769 = 7.1368 \text{ kJ/kg}\cdot\text{K}\end{aligned}$$

Thus,

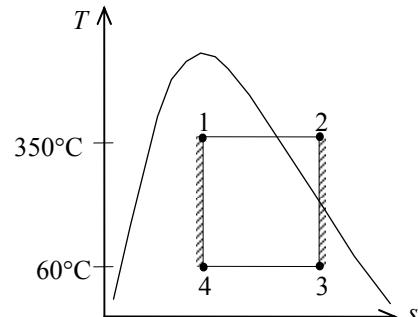

$$\left. \begin{aligned}T_2 &= 350^\circ\text{C} \\s_2 &= 7.1368 \text{ kJ/kg}\cdot\text{K}\end{aligned} \right\} P_2 \approx \mathbf{1.40 \text{ MPa}} \text{ (Table A-6)}$$

(c) The net work can be determined by calculating the enclosed area on the $T-s$ diagram,

$$s_4 = s_f + x_4 s_{fg} = 0.8313 + (0.1)(7.0769) = 1.5390 \text{ kJ/kg}\cdot\text{K}$$

Thus,

$$w_{\text{net}} = \text{Area} = (T_H - T_L)(s_3 - s_4) = (350 - 60)(7.1368 - 1.5390) = \mathbf{1623 \text{ kJ/kg}}$$

The Simple Rankine Cycle

10-6C The four processes that make up the simple ideal cycle are (1) Isentropic compression in a pump, (2) $P = \text{constant}$ heat addition in a boiler, (3) Isentropic expansion in a turbine, and (4) $P = \text{constant}$ heat rejection in a condenser.

10-7C Heat rejected decreases; everything else increases.

10-8C Heat rejected decreases; everything else increases.

10-9C The pump work remains the same, the moisture content decreases, everything else increases.

10-10C The actual vapor power cycles differ from the idealized ones in that the actual cycles involve friction and pressure drops in various components and the piping, and heat loss to the surrounding medium from these components and piping.

10-11C The boiler exit pressure will be (a) lower than the boiler inlet pressure in actual cycles, and (b) the same as the boiler inlet pressure in ideal cycles.

10-12C We would reject this proposal because $w_{\text{turb}} = h_1 - h_2 - q_{\text{out}}$, and any heat loss from the steam will adversely affect the turbine work output.

10-13C Yes, because the saturation temperature of steam at 10 kPa is 45.81°C, which is much higher than the temperature of the cooling water.

10-14 A simple ideal Rankine cycle with R-134a as the working fluid operates between the specified pressure limits. The mass flow rate of R-134a for a given power production and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$h_1 = h_f @ 0.4 \text{ MPa} = 63.94 \text{ kJ/kg}$$

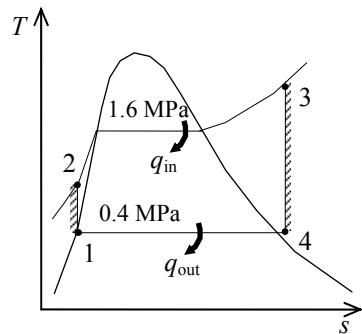

$$\nu_1 = \nu_f @ 0.4 \text{ MPa} = 0.0007907 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= \nu_1(P_2 - P_1) \\ &= (0.0007907 \text{ m}^3/\text{kg})(1600 - 400)\text{kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.95 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 63.94 + 0.95 = 64.89 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 1.6 \text{ MPa} \\ T_3 = 80^\circ\text{C} \end{cases} \quad \begin{cases} h_3 = 305.07 \text{ kJ/kg} \\ s_3 = 0.9875 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 0.4 \text{ MPa} \\ s_4 = s_3 \end{cases} \quad \begin{cases} h_4 = 273.21 \text{ kJ/kg} \end{cases}$$

Thus,

$$q_{in} = h_3 - h_2 = 305.07 - 64.89 = 240.18 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = 273.21 - 63.94 = 209.27 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 240.18 - 209.27 = 30.91 \text{ kJ/kg}$$

The mass flow rate of the refrigerant and the thermal efficiency of the cycle are then

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{750 \text{ kJ/s}}{30.91 \text{ kJ/kg}} = \mathbf{24.26 \text{ kg/s}}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{209.27}{240.18} = \mathbf{0.129}$$

10-15 A simple ideal Rankine cycle with R-134a as the working fluid is considered. The turbine inlet temperature, the cycle thermal efficiency, and the back-work ratio of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$P_1 = P_{\text{sat}} @ 10^\circ\text{C} = 414.89 \text{ kPa}$$

$$h_1 = h_f @ 10^\circ\text{C} = 65.43 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10^\circ\text{C} = 0.0007930 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.0007930 \text{ m}^3/\text{kg})(1400 - 414.89) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.78 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 65.43 + 0.78 = 66.21 \text{ kJ/kg}$$

$$\begin{cases} T_4 = 10^\circ\text{C} \\ x_4 = 0.98 \end{cases} \quad \begin{cases} h_4 = h_f + x_4 h_{fg} = 65.43 + (0.98)(190.73) = 252.35 \text{ kJ/kg} \\ s_4 = s_f + x_4 s_{fg} = 0.25286 + (0.98)(0.67356) = 0.91295 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_3 = 1400 \text{ kPa} \\ s_3 = s_4 = 0.91295 \text{ kJ/kg} \cdot \text{K} \end{cases} \quad \begin{cases} h_3 = 276.91 \text{ kJ/kg} \\ T_3 = 53.0^\circ\text{C} \end{cases}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 276.91 - 66.21 = 210.70 \text{ kJ/kg}$$

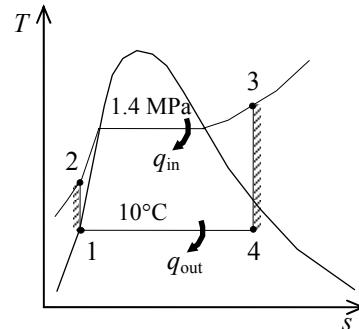

$$q_{\text{out}} = h_4 - h_1 = 252.35 - 65.43 = 186.92 \text{ kJ/kg}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{186.92}{210.70} = \mathbf{0.113}$$

The back-work ratio is determined from

$$r_{bw} = \frac{w_{p,\text{in}}}{W_{T,\text{out}}} = \frac{w_{p,\text{in}}}{h_3 - h_4} = \frac{0.78 \text{ kJ/kg}}{(276.91 - 252.35) \text{ kJ/kg}} = \mathbf{0.0318}$$

10-16 A simple ideal Rankine cycle with water as the working fluid is considered. The work output from the turbine, the heat addition in the boiler, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$P_1 = P_{\text{sat}} @ 40^\circ\text{C} = 7.385 \text{ kPa}$$

$$P_2 = P_{\text{sat}} @ 300^\circ\text{C} = 8588 \text{ kPa}$$

$$h_1 = h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg}$$

$$v_1 = v_f @ 40^\circ\text{C} = 0.001008 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001008 \text{ m}^3/\text{kg})(8588 - 7.385) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 8.65 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 167.53 + 8.65 = 176.18 \text{ kJ/kg}$$

$$\begin{cases} T_3 = 300^\circ\text{C} \\ x_3 = 1 \end{cases} \quad \begin{cases} h_3 = 2749.6 \text{ kJ/kg} \\ s_3 = 5.7059 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} T_4 = 40^\circ\text{C} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{5.7059 - 0.5724}{7.6832} = 0.6681 \\ h_4 = h_f + x_4 h_{fg} = 167.53 + (0.6681)(2406.0) = 1775.1 \text{ kJ/kg} \end{cases}$$

Thus,

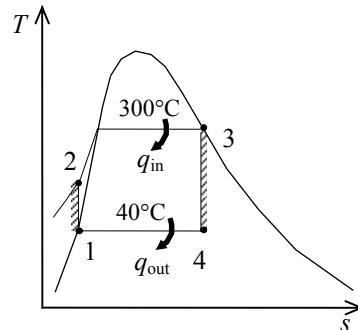

$$w_{T,\text{out}} = h_3 - h_4 = 2749.6 - 1775.1 = \mathbf{974.5 \text{ kJ/kg}}$$

$$q_{\text{in}} = h_3 - h_2 = 2749.6 - 176.18 = \mathbf{2573.4 \text{ kJ/kg}}$$

$$q_{\text{out}} = h_4 - h_1 = 1775.1 - 167.53 = 1607.6 \text{ kJ/kg}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1607.6}{2573.4} = \mathbf{0.375}$$

10-17E A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_{f@3\text{ psia}} = 109.40 \text{ Btu/lbm}$$

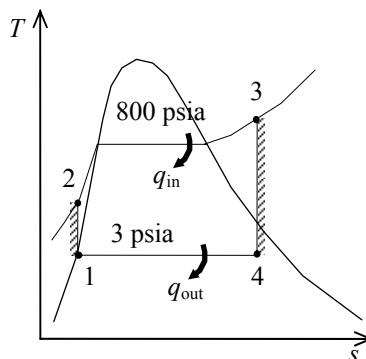

$$v_1 = v_{f@3\text{ psia}} = 0.01630 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01630 \text{ ft}^3/\text{lrbm})(800 - 3)\text{psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 2.40 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 109.40 + 2.40 = 111.81 \text{ Btu/lbm}$$

$$\begin{cases} P_3 = 800 \text{ psia} \\ T_3 = 900^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1456.0 \text{ Btu/lbm} \\ s_3 = 1.6413 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_4 = 3 \text{ psia} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.6413 - 0.2009}{1.6849} = 0.8549 \\ h_4 = h_f + x_4 h_{fg} = 109.40 + (0.8549)(1012.8) = 975.24 \text{ Btu/lbm} \end{cases}$$

Knowing the power output from the turbine the mass flow rate of steam in the cycle is determined from

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) \longrightarrow \dot{m} = \frac{\dot{W}_{T,\text{out}}}{h_3 - h_4} = \frac{1750 \text{ kJ/s}}{(1456.0 - 975.24) \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 3.450 \text{ lbm/s}$$

The rates of heat addition and rejection are

$$\dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (3.450 \text{ lbm/s})(1456.0 - 111.81) \text{ Btu/lbm} = \mathbf{4637 \text{ Btu/s}}$$

$$\dot{Q}_{\text{out}} = \dot{m}(h_4 - h_1) = (3.450 \text{ lbm/s})(975.24 - 109.40) \text{ Btu/lbm} = \mathbf{2987 \text{ Btu/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{2987}{4637} = 0.3559 = \mathbf{35.6\%}$$

10-18E A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The turbine inlet temperature and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 5 \text{ psia} = 130.18 \text{ Btu/lbm}$$

$$v_1 = v_f @ 5 \text{ psia} = 0.01641 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lbm})(2500 - 5) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.58 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 130.18 + 7.58 = 137.76 \text{ Btu/lbm}$$

$$\begin{cases} P_4 = 5 \text{ psia} \\ x_4 = 0.80 \end{cases} \quad \begin{cases} h_4 = h_f + x_4 h_{fg} = 130.18 + (0.80)(1000.5) = 930.58 \text{ Btu/lbm} \\ s_4 = s_f + x_4 s_{fg} = 0.23488 + (0.80)(1.60894) = 1.52203 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_3 = 2500 \text{ psia} \\ s_3 = s_4 = 1.52203 \text{ Btu/lbm} \cdot \text{R} \end{cases} \quad \begin{cases} h_3 = 1450.8 \text{ Btu/lbm} \\ T_3 = 989.2^\circ\text{F} \end{cases}$$

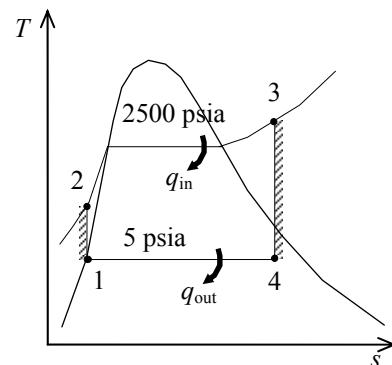

Thus,

$$q_{in} = h_3 - h_2 = 1450.8 - 137.76 = 1313.0 \text{ Btu/lbm}$$

$$q_{out} = h_4 - h_1 = 930.58 - 130.18 = 800.4 \text{ Btu/lbm}$$

The thermal efficiency of the cycle is

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{800.4}{1313.0} = \mathbf{0.390}$$

10-19E A simple steam Rankine cycle operates between the specified pressure limits. The mass flow rate, the power produced by the turbine, the rate of heat addition, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_{f@1\text{ psia}} = 69.72 \text{ Btu/lbm}$$

$$v_1 = v_{f@6\text{ psia}} = 0.01614 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01614 \text{ ft}^3/\text{lrbm})(2500 - 1)\text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.46 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 69.72 + 7.46 = 77.18 \text{ Btu/lbm}$$

$$\begin{cases} P_3 = 2500 \text{ psia} \\ T_3 = 800^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1302.0 \text{ Btu/lbm} \\ s_3 = 1.4116 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_4 = 1 \text{ psia} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{1.4116 - 0.13262}{1.84495} = 0.6932 \\ h_{4s} = h_f + x_{4s} h_{fg} = 69.72 + (0.6932)(1035.7) = 787.70 \text{ Btu/lbm} \end{cases}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1302.0 - (0.90)(1302.0 - 787.70) = 839.13 \text{ kJ/kg}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 1302.0 - 77.18 = 1224.8 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_1 = 839.13 - 69.72 = 769.41 \text{ Btu/lbm}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1224.8 - 769.41 = 455.39 \text{ Btu/lbm}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{1000 \text{ kJ/s}}{455.39 \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{2.081 \text{ lbm/s}}$$

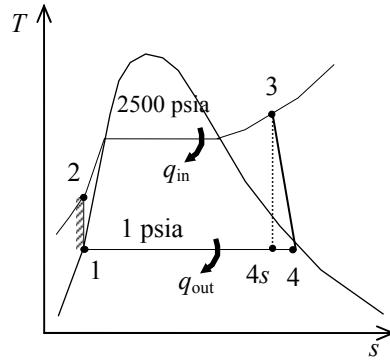

The power output from the turbine and the rate of heat addition are

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (2.081 \text{ lbm/s})(1302.0 - 839.13) \text{ Btu/lbm} \left(\frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = \mathbf{1016 \text{ kW}}$$

$$\dot{Q}_{\text{in}} = \dot{m} q_{\text{in}} = (2.081 \text{ lbm/s})(1224.8 \text{ Btu/lbm}) = \mathbf{2549 \text{ Btu/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1000 \text{ kJ/s}}{2549 \text{ Btu/s}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{0.3718}$$

10-20E A simple steam Rankine cycle operates between the specified pressure limits. The mass flow rate, the power produced by the turbine, the rate of heat addition, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_{f@1\text{ psia}} = 69.72 \text{ Btu/lbm}$$

$$v_1 = v_{f@6\text{ psia}} = 0.01614 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01614 \text{ ft}^3/\text{lrbm})(2500 - 1)\text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.46 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 69.72 + 7.46 = 77.18 \text{ Btu/lbm}$$

$$\begin{cases} P_3 = 2500 \text{ psia} \\ T_3 = 800^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1302.0 \text{ Btu/lbm} \\ s_3 = 1.4116 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_4 = 1 \text{ psia} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{1.4116 - 0.13262}{1.84495} = 0.6932 \\ h_{4s} = h_f + x_{4s} h_{fg} = 69.72 + (0.6932)(1035.7) = 787.70 \text{ Btu/lbm} \end{cases}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1302.0 - (0.90)(1302.0 - 787.70) = 839.13 \text{ kJ/kg}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m}(h_3 - h_4) \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{h_3 - h_4} = \frac{1000 \text{ kJ/s}}{(1302.0 - 839.13) \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 2.048 \text{ lbm/s}$$

The rate of heat addition is

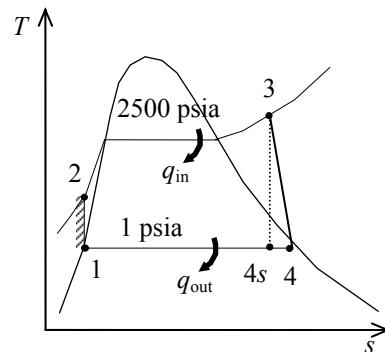

$$\dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (2.048 \text{ lbm/s})(1302.0 - 77.18) \text{ Btu/lbm} \left(\frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = 2508 \text{ Btu/s}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1000 \text{ kJ/s}}{2508 \text{ Btu/s}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 0.3779$$

The thermal efficiency in the previous problem was determined to be 0.3718. The error in the thermal efficiency caused by neglecting the pump work is then

$$\text{Error} = \frac{0.3779 - 0.3718}{0.3718} \times 100 = \mathbf{1.64\%}$$

10-21 A steam power plant operates on a simple ideal Rankine cycle between the specified pressure limits. The thermal efficiency of the cycle, the mass flow rate of the steam, and the temperature rise of the cooling water are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{p,\text{in}} = v_1(P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(7,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 7.06 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 7.06 = 198.87 \text{ kJ/kg}$$

$$P_3 = 7 \text{ MPa} \quad h_3 = 3411.4 \text{ kJ/kg}$$

$$T_3 = 500^\circ\text{C} \quad s_3 = 6.8000 \text{ kJ/kg} \cdot \text{K}$$

$$P_4 = 10 \text{ kPa} \quad \left\{ \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.8000 - 0.6492}{7.4996} = 0.8201 \\ s_4 = s_3 \end{array} \right.$$

$$h_4 = h_f + x_4 h_{fg} = 191.81 + (0.8201)(2392.1) = 2153.6 \text{ kJ/kg}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 3411.4 - 198.87 = 3212.5 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2153.6 - 191.81 = 1961.8 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3212.5 - 1961.8 = 1250.7 \text{ kJ/kg}$$

and

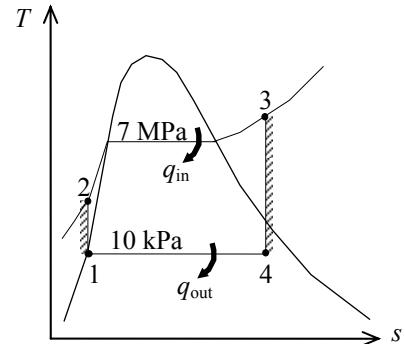

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1250.7 \text{ kJ/kg}}{3212.5 \text{ kJ/kg}} = \mathbf{38.9\%}$$

$$(b) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{45,000 \text{ kJ/s}}{1250.7 \text{ kJ/kg}} = \mathbf{36.0 \text{ kg/s}}$$

(c) The rate of heat rejection to the cooling water and its temperature rise are

$$\dot{Q}_{\text{out}} = \dot{m} q_{\text{out}} = (35.98 \text{ kg/s})(1961.8 \text{ kJ/kg}) = 70,586 \text{ kJ/s}$$

$$\Delta T_{\text{coolingwater}} = \frac{\dot{Q}_{\text{out}}}{(\dot{m}c)_{\text{coolingwater}}} = \frac{70,586 \text{ kJ/s}}{(2000 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot {}^\circ\text{C})} = \mathbf{8.4^\circ\text{C}}$$

10-22 A steam power plant operates on a simple nonideal Rankine cycle between the specified pressure limits. The thermal efficiency of the cycle, the mass flow rate of the steam, and the temperature rise of the cooling water are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@10\text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(7,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.87) \\ &= 8.11 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 8.11 = 199.92 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 7 \text{ MPa} \\ T_3 = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_3 = 3411.4 \text{ kJ/kg} \\ s_3 = 6.8000 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 10 \text{ kPa} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.8000 - 0.6492}{7.4996} = 0.8201 \\ h_{4_s} = h_f + x_4 h_{fg} = 191.81 + (0.820)(2392.1) = 2153.6 \text{ kJ/kg} \end{cases}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4_s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4_s}) \\ &= 3411.4 - (0.87)(3411.4 - 2153.6) = 2317.1 \text{ kJ/kg} \end{aligned}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 3411.4 - 199.92 = 3211.5 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2317.1 - 191.81 = 2125.3 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3211.5 - 2125.3 = 1086.2 \text{ kJ/kg}$$

and

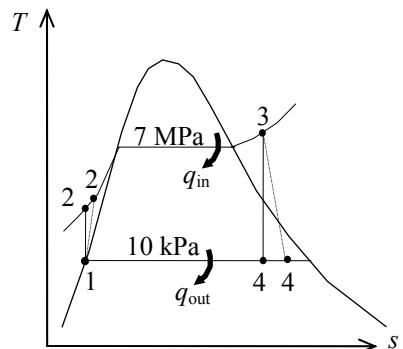

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1086.2 \text{ kJ/kg}}{3211.5 \text{ kJ/kg}} = \mathbf{33.8\%}$$

$$(b) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{45,000 \text{ kJ/s}}{1086.2 \text{ kJ/kg}} = \mathbf{41.43 \text{ kg/s}}$$

(c) The rate of heat rejection to the cooling water and its temperature rise are

$$\dot{Q}_{\text{out}} = \dot{m} q_{\text{out}} = (41.43 \text{ kg/s})(2125.3 \text{ kJ/kg}) = 88,051 \text{ kJ/s}$$

$$\Delta T_{\text{coolingwater}} = \frac{\dot{Q}_{\text{out}}}{(\dot{m}c)_{\text{coolingwater}}} = \frac{88,051 \text{ kJ/s}}{(2000 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})} = \mathbf{10.5^\circ\text{C}}$$

10-23 A simple Rankine cycle with water as the working fluid operates between the specified pressure limits. The rate of heat addition in the boiler, the power input to the pumps, the net power, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned} P_1 &= 50 \text{ kPa} \\ T_1 &= T_{\text{sat } @ 50 \text{ kPa}} - 6.3 = 81.3 - 6.3 = 75^\circ\text{C} \end{aligned} \quad \left\{ \begin{array}{l} h_1 \cong h_f @ 75^\circ\text{C} = 314.03 \text{ kJ/kg} \\ v_1 = v_{f@75^\circ\text{C}} = 0.001026 \text{ m}^3/\text{kg} \end{array} \right.$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001026 \text{ m}^3/\text{kg})(6000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.10 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 314.03 + 6.10 = 320.13 \text{ kJ/kg}$$

$$\begin{aligned} P_3 &= 6000 \text{ kPa} \quad \left\{ \begin{array}{l} h_3 = 3302.9 \text{ kJ/kg} \\ s_3 = 6.7219 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \\ T_3 &= 450^\circ\text{C} \\ P_4 &= 50 \text{ kPa} \quad \left\{ \begin{array}{l} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{6.7219 - 1.0912}{6.5019} = 0.8660 \\ s_4 = s_3 \quad \quad \quad h_{4s} = h_f + x_{4s} h_{fg} = 340.54 + (0.8660)(2304.7) = 2336.4 \text{ kJ/kg} \end{array} \right. \end{aligned}$$

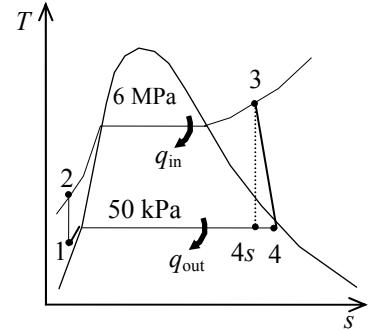

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 3302.9 - (0.94)(3302.9 - 2336.4) = 2394.4 \text{ kJ/kg}$$

Thus,

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}(h_3 - h_2) = (20 \text{ kg/s})(3302.9 - 320.13) \text{ kJ/kg} = \mathbf{59,660 \text{ kW}} \\ \dot{W}_{T,\text{out}} &= \dot{m}(h_3 - h_4) = (20 \text{ kg/s})(3302.9 - 2394.4) \text{ kJ/kg} = 18,170 \text{ kW} \\ \dot{W}_{P,\text{in}} &= \dot{m}w_{p,\text{in}} = (20 \text{ kg/s})(6.10 \text{ kJ/kg}) = \mathbf{122 \text{ kW}} \\ \dot{W}_{\text{net}} &= \dot{W}_{T,\text{out}} - \dot{W}_{P,\text{in}} = 18,170 - 122 = \mathbf{18,050 \text{ kW}} \end{aligned}$$

and

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{18,050}{59,660} = \mathbf{0.3025}$$

- 10-24** The change in the thermal efficiency of the cycle in Prob. 10-23 due to a pressure drop in the boiler is to be determined.

Analysis We use the following EES routine to obtain the solution.

Discussion The thermal efficiency without a pressure drop was obtained to be 0.3025.

10-25 The net work outputs and the thermal efficiencies for a Carnot cycle and a simple ideal Rankine cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Rankine cycle analysis: From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 50 \text{ kPa} = 340.54 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 50 \text{ kPa} = 0.001030 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(5000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.10 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 340.54 + 5.10 = 345.64 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 5 \text{ MPa} \\ x_3 = 1 \end{cases} \quad \begin{cases} h_3 = 2794.2 \text{ kJ/kg} \\ s_3 = 5.9737 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 50 \text{ kPa} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{5.9737 - 1.09120}{6.5019} = 0.7509 \\ h_4 = h_f + x_4 h_{fg} = 340.54 + (0.7509)(2304.7) \end{cases}$$

$$= 2071.2 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 2794.2 - 345.64 = 2448.6 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2071.2 - 340.54 = 1730.7 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2448.6 - 1730.7 = \mathbf{717.9 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1730.7}{2448.6} = 0.2932 = \mathbf{29.3\%}$$

(b) Carnot Cycle analysis:

$$\begin{cases} P_3 = 5 \text{ MPa} \\ x_3 = 1 \end{cases} \quad \begin{cases} h_3 = 2794.2 \text{ kJ/kg} \\ T_3 = 263.9^\circ\text{C} \end{cases}$$

$$\begin{cases} T_2 = T_3 = 263.9^\circ\text{C} \\ x_2 = 0 \end{cases} \quad \begin{cases} h_2 = 1154.5 \text{ kJ/kg} \\ s_2 = 2.9207 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

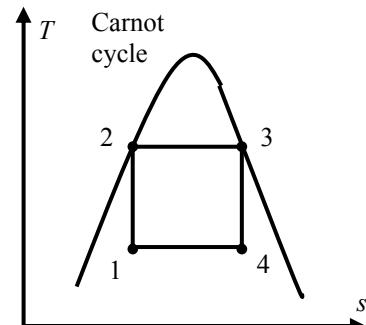

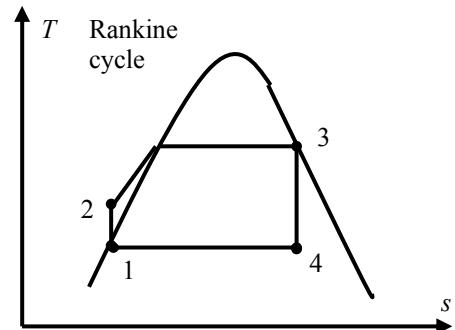

$$\begin{cases} P_1 = 50 \text{ kPa} \\ s_1 = s_2 \end{cases} \quad \begin{cases} x_1 = \frac{s_1 - s_f}{s_{fg}} = \frac{2.9207 - 1.0912}{6.5019} = 0.2814 \\ h_1 = h_f + x_1 h_{fg} \\ = 340.54 + (0.2814)(2304.7) = 989.05 \text{ kJ/kg} \end{cases}$$

$$q_{\text{in}} = h_3 - h_2 = 2794.2 - 1154.5 = 1639.7 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2071.2 - 340.54 = 1082.2 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1639.7 - 1082.2 = \mathbf{557.5 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1082.2}{1639.7} = 0.3400 = \mathbf{34.0\%}$$

10-26 A 120-MW coal-fired steam power plant operates on a simple ideal Rankine cycle between the specified pressure limits. The overall plant efficiency and the required rate of the coal supply are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$v_1 = v_f @ 15 \text{ kPa} = 0.0010140 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001014 \text{ m}^3/\text{kg})(9000 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 9.11 \text{ kJ/kg} \end{aligned}$$

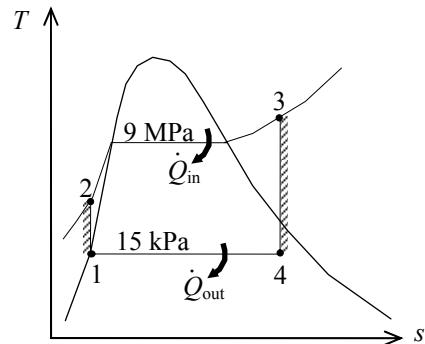

$$h_2 = h_1 + w_{p,\text{in}} = 225.94 + 9.11 = 235.05 \text{ kJ/kg}$$

$$P_3 = 9 \text{ MPa} \quad h_3 = 3512.0 \text{ kJ/kg}$$

$$T_3 = 550^\circ\text{C} \quad s_3 = 6.8164 \text{ kJ/kg} \cdot \text{K}$$

$$\begin{aligned} P_4 = 15 \text{ kPa} \quad x_4 &= \frac{s_4 - s_f}{s_{fg}} = \frac{6.8164 - 0.7549}{7.2522} = 0.8358 \\ s_4 = s_3 \quad & \end{aligned}$$

$$h_4 = h_f + x_4 h_{fg} = 225.94 + (0.8358)(2372.4) = 2208.8 \text{ kJ/kg}$$

The thermal efficiency is determined from

$$q_{\text{in}} = h_3 - h_2 = 3512.0 - 235.05 = 3276.9 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2208.8 - 225.94 = 1982.9 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1982.9}{3276.9} = 0.3949$$

Thus,

$$\eta_{\text{overall}} = \eta_{\text{th}} \times \eta_{\text{comb}} \times \eta_{\text{gen}} = (0.3949)(0.75)(0.96) = 0.2843 = 28.4\%$$

(b) Then the required rate of coal supply becomes

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{overall}}} = \frac{120,000 \text{ kJ/s}}{0.2843} = 422,050 \text{ kJ/s}$$

and

$$\dot{m}_{\text{coal}} = \frac{\dot{Q}_{\text{in}}}{C_{\text{coal}}} = \frac{422,050 \text{ kJ/s}}{29,300 \text{ kJ/kg}} = 14.404 \text{ kg/s} = 51.9 \text{ tons/h}$$

10-27 A single-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The mass flow rate of steam through the turbine, the isentropic efficiency of the turbine, the power output from the turbine, and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\begin{aligned} T_1 &= 230^\circ\text{C} \\ x_1 &= 0 \quad h_1 = 990.14 \text{ kJ/kg} \\ P_2 &= 500 \text{ kPa} \\ h_2 &= h_1 = 990.14 \text{ kJ/kg} \quad x_2 = \frac{h_2 - h_f}{h_{fg}} = \frac{990.14 - 640.09}{2108} = 0.1661 \end{aligned}$$

The mass flow rate of steam through the turbine is

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = \mathbf{38.20 \text{ kg/s}}$$

(b) Turbine:

$$\begin{aligned} P_3 &= 500 \text{ kPa} \quad h_3 = 2748.1 \text{ kJ/kg} \\ x_3 &= 1 \quad s_3 = 6.8207 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_4 &= 10 \text{ kPa} \quad h_{4s} = 2160.3 \text{ kJ/kg} \\ s_4 &= s_3 \end{aligned}$$

$$\begin{aligned} P_4 &= 10 \text{ kPa} \quad h_4 = h_f + x_4 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg} \\ x_4 &= 0.90 \end{aligned}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{2748.1 - 2344.7}{2748.1 - 2160.3} = \mathbf{0.686}$$

(c) The power output from the turbine is

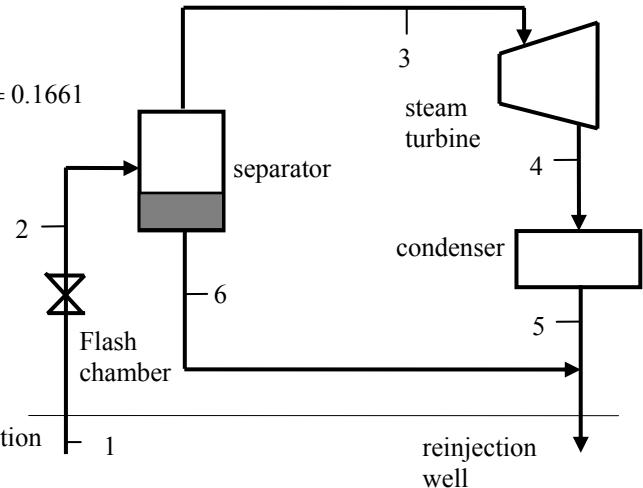

$$\dot{W}_{T,\text{out}} = \dot{m}_3 (h_3 - h_4) = (38.20 \text{ kg})(2748.1 - 2344.7) \text{ kJ/kg} = \mathbf{15,410 \text{ kW}}$$

(d) We use saturated liquid state at the standard temperature for dead state enthalpy

$$\begin{aligned} T_0 &= 25^\circ\text{C} \\ x_0 &= 0 \quad h_0 = 104.83 \text{ kJ/kg} \end{aligned}$$

$$\dot{E}_{\text{in}} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{15,410}{203,622} = 0.0757 = \mathbf{7.6\%}$$

10-28 A double-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The temperature of the steam at the exit of the second flash chamber, the power produced from the second turbine, and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = 0.1661$$

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = 38.20 \text{ kg/s}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 0.1661 = 191.80 \text{ kg/s}$$

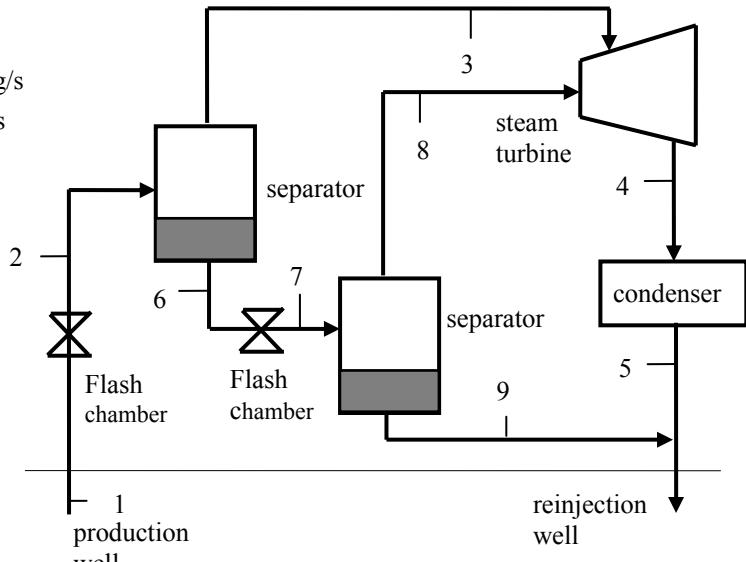

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} h_3 = 2748.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = 2344.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = 640.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_7 = 150 \text{ kPa} \\ h_7 = h_6 \end{array} \right\} T_7 = 111.35^\circ\text{C}$$

$$\left. \begin{array}{l} P_8 = 150 \text{ kPa} \\ x_8 = 1 \end{array} \right\} h_8 = 2693.1 \text{ kJ/kg}$$

(b) The mass flow rate at the lower stage of the turbine is

$$\dot{m}_8 = x_7 \dot{m}_6 = (0.0777)(191.80 \text{ kg/s}) = 14.90 \text{ kg/s}$$

The power outputs from the high and low pressure stages of the turbine are

$$\dot{W}_{T1,\text{out}} = \dot{m}_3(h_3 - h_4) = (38.20 \text{ kg/kg})(2748.1 - 2344.7) \text{ kJ/kg} = 15,410 \text{ kW}$$

$$\dot{W}_{T2,\text{out}} = \dot{m}_8(h_8 - h_4) = (14.90 \text{ kg/kg})(2693.1 - 2344.7) \text{ kJ/kg} = 5191 \text{ kW}$$

(c) We use saturated liquid state at the standard temperature for the dead state enthalpy

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} = \dot{m}_1(h_1 - h_0) = (230 \text{ kg/s})(990.14 - 104.83) \text{ kJ/kg} = 203,621 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{15,410 + 5193}{203,621} = 0.101 = 10.1\%$$

10-29 A combined flash-binary geothermal power plant uses hot geothermal water at 230°C as the heat source. The mass flow rate of isobutane in the binary cycle, the net power outputs from the steam turbine and the binary cycle, and the thermal efficiencies for the binary cycle and the combined plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = 0.1661$$

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = 38.20 \text{ kg/s}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 38.20 = 191.80 \text{ kg/s}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} h_3 = 2748.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = 2344.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_c = 0 \end{array} \right\} h_6 = 640.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = 90^\circ\text{C} \\ x_7 = 0 \end{array} \right\} h_7 = 377.04 \text{ kJ/kg}$$

The isobutane properties are obtained from EES:

$$\left. \begin{array}{l} P_8 = 3250 \text{ kPa} \\ T_8 = 145^\circ\text{C} \end{array} \right\} h_8 = 755.05 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 400 \text{ kPa} \\ T_9 = 80^\circ\text{C} \end{array} \right\} h_9 = 691.01 \text{ kJ/kg}$$

$$P_{10} = 400 \text{ kPa} \quad \begin{cases} h_{10} = 270.83 \text{ kJ/kg} \\ x_{10} = 0 \end{cases} \quad \begin{cases} v_{10} = 0.001839 \text{ m}^3/\text{kg} \end{cases}$$

$$w_{p,\text{in}} = \nu_{10}(P_{11} - P_{10})/\eta_p = (0.001819 \text{ m}^3/\text{kg})(3250 - 400) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.90 = 5.82 \text{ kJ/kg.}$$

$$h_{11} = h_{10} + w_{p,\text{in}} = 270.83 + 5.82 = 276.65 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives

$$\dot{m}_6(h_6 - h_7) = \dot{m}_{\text{iso}}(h_8 - h_{11})$$

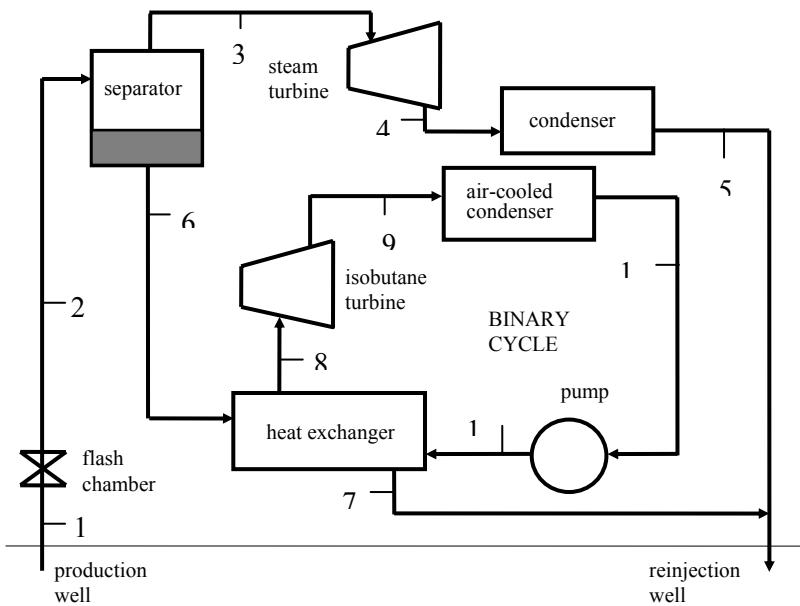

$$(191.81 \text{ kg/s})(640.09 - 377.04) \text{ kJ/kg} = \dot{m}_{\text{iso}} (755.05 - 276.65) \text{ kJ/kg} \longrightarrow \dot{m}_{\text{iso}} = 105.46 \text{ kg/s}$$

(b) The power outputs from the steam turbine and the binary cycle are

$$\dot{W}_{T\text{ steam}} = \dot{m}_3(h_3 - h_4) = (38.19 \text{ kJ/kg})(2748.1 - 2344.7) \text{ kJ/kg} = \mathbf{15,410 \text{ kW}}$$

$$\dot{W}_{T,\text{iso}} = \dot{m}_{iso} (h_8 - h_9) = (105.46 \text{ kJ/kg})(755.05 - 691.01) \text{ kJ/kg} = 6753 \text{ kW}$$

$$\dot{W}_{\text{net binary}} = \dot{W}_{\text{T iso}} - \dot{m}_{\text{iso}} w_{p,in} = 6753 - (105.46 \text{ kg/s})(5.82 \text{ kJ/kg}) = \mathbf{6139 \text{ kW}}$$

(c) The thermal efficiencies of the binary cycle and the combined plant are

$$\dot{Q}_{\text{in,binary}} = \dot{m}_{\text{iso}}(h_8 - h_{11}) = (105.46 \text{ kJ/kg})(755.05 - 276.65) \text{ kJ/kg} = 50,454 \text{ kW}$$

$$\eta_{\text{th,binary}} = \frac{\dot{W}_{\text{net,binary}}}{\dot{Q}_{\text{in,binary}}} = \frac{6139}{50,454} = 0.122 = \mathbf{12.2\%}$$

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

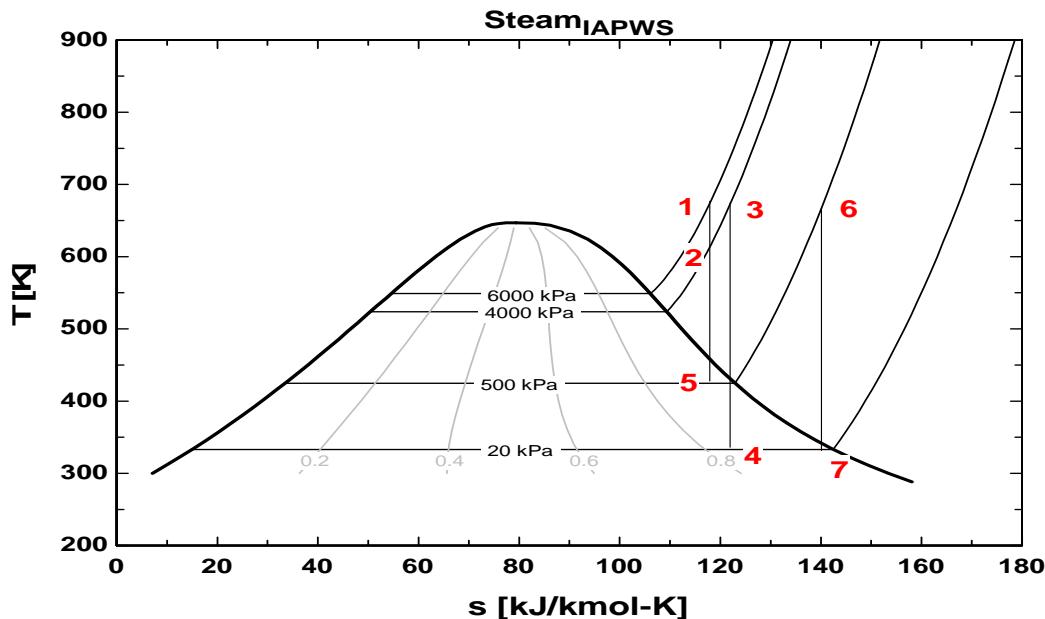

$$\dot{E}_{\text{in}} = \dot{m}_1(h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th,plant}} = \frac{\dot{W}_{\text{T,steam}} + \dot{W}_{\text{net,binary}}}{\dot{E}_{\text{in}}} = \frac{15,410 + 6139}{203,622} = 0.106 = \mathbf{10.6\%}$$

The Reheat Rankine Cycle

10-30C The pump work remains the same, the moisture content decreases, everything else increases.

10-31C The $T-s$ diagram shows two reheat cases for the reheat Rankine cycle similar to the one shown in Figure 10-11. In the first case there is expansion through the high-pressure turbine from 6000 kPa to 4000 kPa between states 1 and 2 with reheat at 4000 kPa to state 3 and finally expansion in the low-pressure turbine to state 4. In the second case there is expansion through the high-pressure turbine from 6000 kPa to 500 kPa between states 1 and 5 with reheat at 500 kPa to state 6 and finally expansion in the low-pressure turbine to state 7. Increasing the pressure for reheating increases the average temperature for heat addition makes the energy of the steam more available for doing work, see the reheat process 2 to 3 versus the reheat process 5 to 6. Increasing the reheat pressure will increase the cycle efficiency. However, as the reheating pressure increases, the amount of condensation increases during the expansion process in the low-pressure turbine, state 4 versus state 7. An optimal pressure for reheating generally allows for the moisture content of the steam at the low-pressure turbine exit to be in the range of 10 to 15% and this corresponds to quality in the range of 85 to 90%.

10-32C The thermal efficiency of the simple ideal Rankine cycle will probably be higher since the average temperature at which heat is added will be higher in this case.

10-33 An ideal reheat steam Rankine cycle produces 5000 kW power. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{f@10\text{ kPa}} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.001010 \text{ m}^3/\text{kg})(8000 - 10)\text{kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 8.07 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 191.81 + 8.07 = 199.88 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 8000 \text{ kPa} \\ T_3 = 450^\circ\text{C} \end{cases} \quad \begin{cases} h_3 = 3273.3 \text{ kJ/kg} \\ s_3 = 6.5579 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 500 \text{ kPa} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.5579 - 1.8604}{4.9603} = 0.9470 \\ h_4 = h_f + x_4 h_{fg} = 640.09 + (0.9470)(2108.0) = 2636.4 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_5 = 500 \text{ kPa} \\ T_5 = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_5 = 3484.5 \text{ kJ/kg} \\ s_5 = 8.0893 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_6 = 10 \text{ kPa} \\ s_6 = s_5 \end{cases} \quad \begin{cases} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{8.0893 - 0.6492}{7.4996} = 0.9921 \\ h_6 = h_f + x_6 h_{fg} = 191.81 + (0.9921)(2392.1) = 2564.9 \text{ kJ/kg} \end{cases}$$

Thus,

$$q_{in} = (h_3 - h_2) + (h_5 - h_4) = 3273.3 - 199.88 + 3484.5 - 2636.4 = 3921.5 \text{ kJ/kg}$$

$$q_{out} = h_6 - h_1 = 2564.9 - 191.81 = 2373.1 \text{ kJ/kg}$$

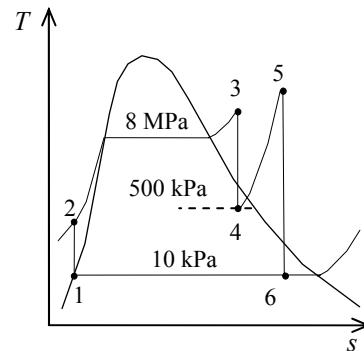

$$w_{net} = q_{in} - q_{out} = 3921.5 - 2373.1 = 1548.5 \text{ kJ/kg}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{net} = \dot{m}(h_3 - h_4) \longrightarrow \dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{5000 \text{ kJ/s}}{1548.5 \text{ kJ/kg}} = \mathbf{3.229 \text{ kg/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{2373.1}{3921.5} = \mathbf{0.395}$$

10-34 An ideal reheat steam Rankine cycle produces 2000 kW power. The mass flow rate of the steam, the rate of heat transfer in the reheat, the power used by the pumps, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_f @ 100 \text{ kPa} = 417.51 \text{ kJ/kg}$$

$$v_1 = v_f @ 100 \text{ kPa} = 0.001043 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.001043 \text{ m}^3/\text{kg})(15000 - 100) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.54 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 417.51 + 15.54 = 433.05 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 15,000 \text{ kPa} \\ T_3 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3157.9 \text{ kJ/kg} \\ s_3 = 6.1434 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2000 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.1434 - 2.4467}{3.8923} = 0.9497 \\ h_4 = h_f + x_4 h_{fg} = 908.47 + (0.9497)(1889.8) = 2703.3 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_5 = 2000 \text{ kPa} \\ T_5 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3358.2 \text{ kJ/kg} \\ s_5 = 7.2866 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 100 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.2866 - 1.3028}{6.0562} = 0.9880 \\ h_6 = h_f + x_6 h_{fg} = 417.51 + (0.9880)(22257.5) = 2648.0 \text{ kJ/kg} \end{array}$$

Thus,

$$q_{in} = (h_3 - h_2) + (h_5 - h_4) = 3157.9 - 433.05 + 3358.2 - 2703.3 = 3379.8 \text{ kJ/kg}$$

$$q_{out} = h_6 - h_1 = 2648.0 - 417.51 = 2230.5 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 379.8 - 2230.5 = 1149.2 \text{ kJ/kg}$$

The power produced by the cycle is

$$\dot{W}_{net} = \dot{m}w_{net} = (1.74 \text{ kg/s})(1149.2 \text{ kJ/kg}) = \mathbf{2000 \text{ kW}}$$

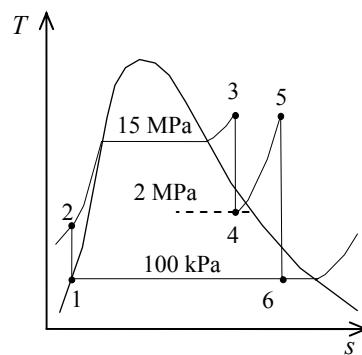

The rate of heat transfer in the reheater is

$$\dot{Q}_{reheater} = \dot{m}(h_5 - h_4) = (1.740 \text{ kg/s})(3358.2 - 2703.3) \text{ kJ/kg} = \mathbf{1140 \text{ kW}}$$

$$\dot{W}_{p,in} = \dot{m}w_{p,in} = (1.740 \text{ kg/s})(15.54 \text{ kJ/kg}) = \mathbf{27 \text{ kW}}$$

and the thermal efficiency of the cycle is

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{2230.5}{3379.8} = \mathbf{0.340}$$

10-35 A steam power plant that operates on the ideal reheat Rankine cycle is considered. The turbine work output and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@20\text{ kPa}} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_{f@20\text{ kPa}} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(6000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.08 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 6.08 = 257.50 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 6 \text{ MPa} \\ T_3 = 400^\circ\text{C} \end{cases} \begin{cases} h_3 = 3178.3 \text{ kJ/kg} \\ s_3 = 6.5432 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 2 \text{ MPa} \\ s_4 = s_3 \end{cases} \begin{cases} h_4 = 2901.0 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_5 = 2 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{cases} \begin{cases} h_5 = 3248.4 \text{ kJ/kg} \\ s_5 = 7.1292 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_6 = 20 \text{ kPa} \\ s_6 = s_5 \end{cases} \begin{cases} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.1292 - 0.8320}{7.0752} = 0.8900 \\ h_6 = h_f + x_6 h_{fg} = 251.42 + (0.8900)(2357.5) = 2349.7 \text{ kJ/kg} \end{cases}$$

The turbine work output and the thermal efficiency are determined from

$$w_{T,\text{out}} = (h_3 - h_4) + (h_5 - h_6) = 3178.3 - 2901.0 + 3248.4 - 2349.7 = \mathbf{1176 \text{ kJ/kg}}$$

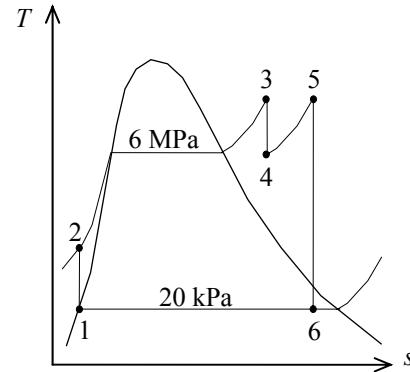

and

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3178.3 - 257.50 + 3248.4 - 2901.0 = 3268 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 1176 - 6.08 = 1170 \text{ kJ/kg}$$

Thus,

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1170 \text{ kJ/kg}}{3268 \text{ kJ/kg}} = 0.358 = \mathbf{35.8\%}$$

10-36 Problem 10-35 is reconsidered. The problem is to be solved by the diagram window data entry feature of EES by including the effects of the turbine and pump efficiencies and reheat on the steam quality at the low-pressure turbine exit. Also, the $T-s$ diagram is to be plotted.

Analysis The problem is solved using EES, and the solution is given below.

10-37E An ideal reheat steam Rankine cycle produces 5000 kW power. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E or EES),

$$h_1 = h_f @ 10 \text{ psia} = 161.25 \text{ Btu/lbm}$$

$$v_1 = v_{f@10 \text{ psia}} = 0.01659 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.01659 \text{ ft}^3/\text{lrbm})(600 - 10) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 1.81 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 161.25 + 1.81 = 163.06 \text{ Btu/lbm}$$

$$\begin{cases} P_3 = 600 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1289.9 \text{ Btu/lbm} \\ s_3 = 1.5325 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_4 = 200 \text{ psia} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5325 - 0.54379}{1.00219} = 0.9865 \\ h_4 = h_f + x_4 h_{fg} = 355.46 + (0.9865)(843.33) = 1187.5 \text{ Btu/lbm} \end{cases}$$

$$\begin{cases} P_5 = 200 \text{ psia} \\ T_5 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_5 = 1322.3 \text{ Btu/lbm} \\ s_5 = 1.6771 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_6 = 10 \text{ psia} \\ s_6 = s_5 \end{cases} \quad \begin{cases} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{1.6771 - 0.28362}{1.50391} = 0.9266 \\ h_6 = h_f + x_6 h_{fg} = 161.25 + (0.9266)(981.82) = 1071.0 \text{ Btu/lbm} \end{cases}$$

Thus,

$$q_{in} = (h_3 - h_2) + (h_5 - h_4) = 1289.9 - 163.06 + 1322.3 - 1187.5 = 1261.7 \text{ Btu/lbm}$$

$$q_{out} = h_6 - h_1 = 1071.0 - 161.25 = 909.7 \text{ Btu/lbm}$$

$$w_{net} = q_{in} - q_{out} = 1261.7 - 909.8 = 352.0 \text{ Btu/lbm}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{net} = \dot{m} w_{net} \longrightarrow \dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{5000 \text{ kJ/s}}{352.0 \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 13.47 \text{ lbm/s}$$

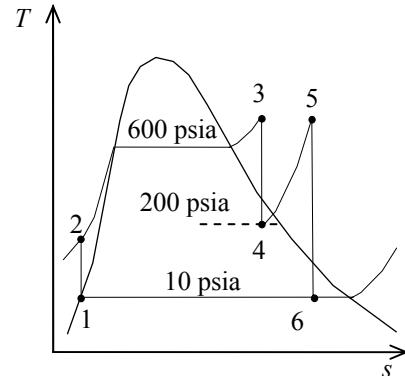

The rates of heat addition and rejection are

$$\dot{Q}_{in} = \dot{m} q_{in} = (13.47 \text{ lbm/s})(1261.7 \text{ Btu/lbm}) = \mathbf{16,995 \text{ Btu/s}}$$

$$\dot{Q}_{out} = \dot{m} q_{out} = (13.47 \text{ lbm/s})(909.7 \text{ Btu/lbm}) = \mathbf{12,250 \text{ Btu/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{5000 \text{ kJ/s}}{16,990 \text{ Btu/s}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{0.2790}$$

10-38E An ideal reheat steam Rankine cycle produces 5000 kW power. The rates of heat addition and rejection, and the thermal efficiency of the cycle are to be determined for a reheat pressure of 100 psia.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E or EES),

$$h_1 = h_f @ 10 \text{ psia} = 161.25 \text{ Btu/lbm}$$

$$v_1 = v_f @ 6 \text{ psia} = 0.01659 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.01659 \text{ ft}^3/\text{lrbm})(600 - 10) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 1.81 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 161.25 + 1.81 = 163.06 \text{ Btu/lbm}$$

$$\begin{cases} P_3 = 600 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1289.9 \text{ Btu/lbm} \\ s_3 = 1.5325 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_4 = 100 \text{ psia} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5325 - 0.47427}{1.12888} = 0.9374 \\ h_4 = h_f + x_4 h_{fg} = 298.51 + (0.9374)(888.99) = 1131.9 \text{ Btu/lbm} \end{cases}$$

$$\begin{cases} P_5 = 100 \text{ psia} \\ T_5 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_5 = 1329.4 \text{ Btu/lbm} \\ s_5 = 1.7586 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_6 = 10 \text{ psia} \\ s_6 = s_5 \end{cases} \quad \begin{cases} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{1.7586 - 0.28362}{1.50391} = 0.9808 \\ h_6 = h_f + x_6 h_{fg} = 161.25 + (0.9808)(981.82) = 1124.2 \text{ Btu/lbm} \end{cases}$$

Thus,

$$q_{in} = (h_3 - h_2) + (h_5 - h_4) = 1289.9 - 163.07 + 1329.4 - 1131.9 = 1324.4 \text{ Btu/lbm}$$

$$q_{out} = h_6 - h_1 = 1124.2 - 161.25 = 962.9 \text{ Btu/lbm}$$

$$w_{net} = q_{in} - q_{out} = 1324.4 - 962.9 = 361.5 \text{ Btu/lbm}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{net} = \dot{m} w_{net} \longrightarrow \dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{5000 \text{ kJ/s}}{361.5 \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 13.11 \text{ lbm/s}$$

The rates of heat addition and rejection are

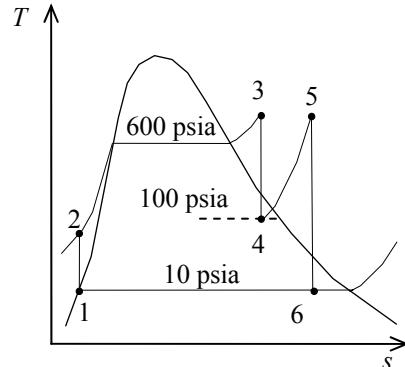

$$\dot{Q}_{in} = \dot{m} q_{in} = (13.11 \text{ lbm/s})(1324.4 \text{ Btu/lbm}) = \mathbf{17,360 \text{ Btu/s}}$$

$$\dot{Q}_{out} = \dot{m} q_{out} = (13.11 \text{ lbm/s})(962.9 \text{ Btu/lbm}) = \mathbf{12,620 \text{ Btu/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{5000 \text{ kJ/s}}{17,360 \text{ Btu/s}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{0.2729}$$

Discussion The thermal efficiency for 200 psia reheat pressure was determined in the previous problem to be 0.2790. Thus, operating the reheat at 100 psia causes a slight decrease in the thermal efficiency.

10-39 An ideal reheat Rankine with water as the working fluid is considered. The temperatures at the inlet of both turbines, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

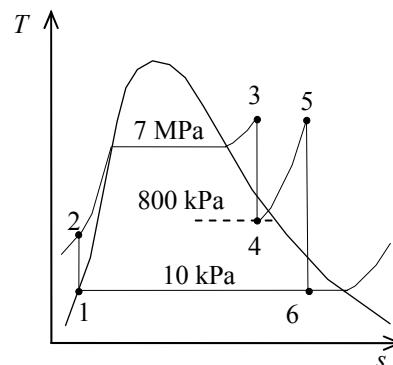

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.001010 \text{ m}^3/\text{kg})(7000 - 10) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 7.06 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 191.81 + 7.06 = 198.87 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 800 \text{ kPa} \\ x_4 = 0.93 \end{array} \right\} \quad \left. \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 720.87 + (0.93)(2047.5) = 2625.0 \text{ kJ/kg} \\ s_4 = s_f + x_4 s_{fg} = 2.0457 + (0.93)(4.6160) = 6.3385 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_3 = 7000 \text{ kPa} \\ s_3 = s_4 \end{array} \right\} \quad \left. \begin{array}{l} h_3 = 3085.5 \text{ kJ/kg} \\ T_3 = 373.3^\circ\text{C} \end{array} \right.$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ x_6 = 0.90 \end{array} \right\} \quad \left. \begin{array}{l} h_6 = h_f + x_6 h_{fg} = 191.81 + (0.93)(2392.1) = 2416.4 \text{ kJ/kg} \\ s_6 = s_f + x_6 s_{fg} = 0.6492 + (0.93)(7.4996) = 7.6239 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_5 = 800 \text{ kPa} \\ s_5 = s_6 \end{array} \right\} \quad \left. \begin{array}{l} h_5 = 3302.0 \text{ kJ/kg} \\ T_5 = 416.2^\circ\text{C} \end{array} \right.$$

Thus,

$$q_{in} = (h_3 - h_2) + (h_5 - h_4) = 3085.5 - 198.87 + 3302.0 - 2625.0 = 3563.6 \text{ kJ/kg}$$

$$q_{out} = h_6 - h_1 = 2416.4 - 191.81 = 2224.6 \text{ kJ/kg}$$

and

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{2224.6}{3563.6} = 0.3757 = 37.6\%$$

10-40 A steam power plant that operates on an ideal reheat Rankine cycle between the specified pressure limits is considered. The pressure at which reheating takes place, the total rate of heat input in the boiler, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{\text{sat}@10 \text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{\text{sat}@10 \text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.14 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 15 \text{ MPa} \\ T_3 = 500^\circ\text{C} \end{cases} \begin{cases} h_3 = 3310.8 \text{ kJ/kg} \\ s_3 = 6.3480 \text{ kJ/kg}\cdot\text{K} \end{cases}$$

$$\begin{cases} P_6 = 10 \text{ kPa} \\ s_6 = s_5 \end{cases} \begin{cases} h_6 = h_f + x_6 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg} \\ s_6 = s_f + x_6 s_{fg} = 0.6492 + (0.90)(7.4996) = 7.3988 \text{ kJ/kg}\cdot\text{K} \end{cases}$$

$$\begin{cases} T_5 = 500^\circ\text{C} \\ s_5 = s_6 \end{cases} \begin{cases} P_5 = 2150 \text{ kPa} \text{ (the reheat pressure)} \\ h_5 = 3466.61 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_4 = 2.15 \text{ MPa} \\ s_4 = s_3 \end{cases} \begin{cases} h_4 = 2817.2 \text{ kJ/kg} \end{cases}$$

(b) The rate of heat supply is

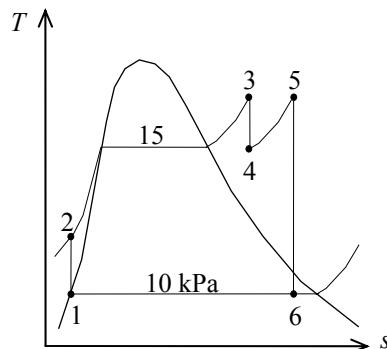

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}[(h_3 - h_2) + (h_5 - h_4)] \\ &= (12 \text{ kg/s})(3310.8 - 206.95 + 3466.61 - 2817.2) \text{ kJ/kg} \\ &= \mathbf{45,039 \text{ kW}} \end{aligned}$$

(c) The thermal efficiency is determined from

$$\dot{Q}_{\text{out}} = \dot{m}(h_6 - h_1) = (12 \text{ kg/s})(2344.7 - 191.81) \text{ kJ/kg} = 25,835 \text{ kJ/s}$$

Thus,

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{25,834 \text{ kJ/s}}{45,039 \text{ kJ/s}} = \mathbf{42.6\%}$$

10-41 A steam power plant that operates on a reheat Rankine cycle is considered. The condenser pressure, the net power output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned} P_3 &= 12.5 \text{ MPa} \\ T_3 &= 550^\circ\text{C} \end{aligned} \quad \left. \begin{aligned} h_3 &= 3476.5 \text{ kJ/kg} \\ s_3 &= 6.6317 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right.$$

$$\begin{aligned} P_4 &= 2 \text{ MPa} \\ s_{4s} &= s_3 \end{aligned} \quad \left. \begin{aligned} h_{4s} &= 2948.1 \text{ kJ/kg} \end{aligned} \right.$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

$$\begin{aligned} \rightarrow h_4 &= h_3 - \eta_T(h_3 - h_{4s}) \\ &= 3476.5 - (0.85)(3476.5 - 2948.1) \\ &= 3027.3 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} P_5 &= 2 \text{ MPa} \\ T_5 &= 450^\circ\text{C} \end{aligned} \quad \left. \begin{aligned} h_5 &= 3358.2 \text{ kJ/kg} \\ s_5 &= 7.2815 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right.$$

$$\begin{aligned} P_6 &=? \\ x_6 &= 0.95 \end{aligned} \quad \left. \begin{aligned} h_6 &= \text{(Eq. 1)} \end{aligned} \right.$$

$$\begin{aligned} P_6 &=? \\ s_6 &= s_5 \end{aligned} \quad \left. \begin{aligned} h_{6s} &= \text{(Eq. 2)} \end{aligned} \right.$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) = 3358.2 - (0.85)(3358.2 - h_{6s}) \quad \text{(Eq. 3)}$$

The pressure at state 6 may be determined by a trial-error approach from the steam tables or by using EES from the above three equations:

$$P_6 = 9.73 \text{ kPa}, \quad h_6 = 2463.3 \text{ kJ/kg},$$

(b) Then,

$$h_1 = h_f @ 9.73 \text{ kPa} = 189.57 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1)/\eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(12,500 - 9.73 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.90) \\ &= 14.02 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 189.57 + 14.02 = 203.59 \text{ kJ/kg}$$

Cycle analysis:

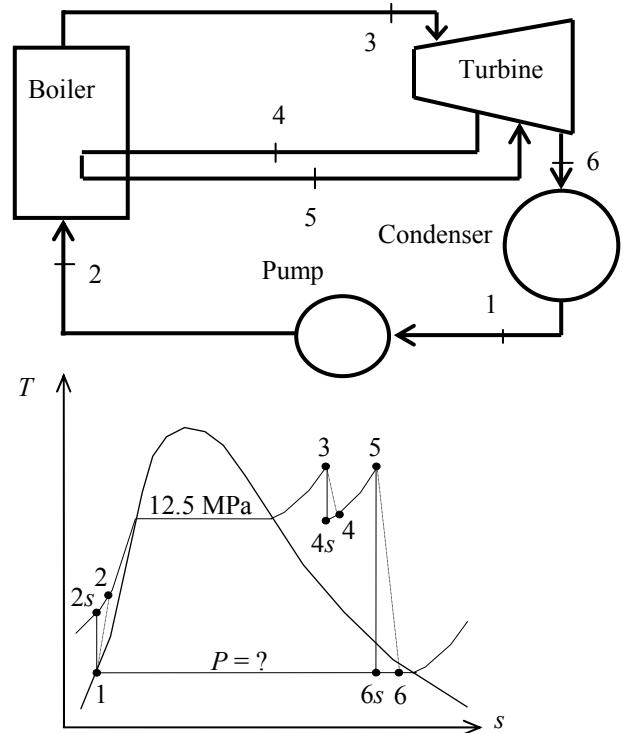

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3476.5 - 203.59 + 3358.2 - 2463.3 = 3603.8 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2463.3 - 189.57 = 2273.7 \text{ kJ/kg}$$

$$\dot{W}_{\text{net}} = \dot{m}(q_{\text{in}} - q_{\text{out}}) = (7.7 \text{ kg/s})(3603.8 - 2273.7) \text{ kJ/kg} = \mathbf{10,242 \text{ kW}}$$

(c) The thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2273.7 \text{ kJ/kg}}{3603.8 \text{ kJ/kg}} = 0.369 = \mathbf{36.9\%}$$

Regenerative Rankine Cycle

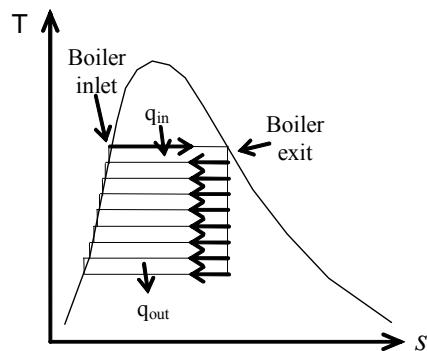

10-42C Moisture content remains the same, everything else decreases.

10-43C This is a smart idea because we waste little work potential but we save a lot from the heat input. The extracted steam has little work potential left, and most of its energy would be part of the heat rejected anyway. Therefore, by regeneration, we utilize a considerable amount of heat by sacrificing little work output.

10-44C In open feedwater heaters, the two fluids actually mix, but in closed feedwater heaters there is no mixing.

10-45C Both cycles would have the same efficiency.

10-46C To have the same thermal efficiency as the Carnot cycle, the cycle must receive and reject heat isothermally. Thus the liquid should be brought to the saturated liquid state at the boiler pressure isothermally, and the steam must be a saturated vapor at the turbine inlet. This will require an infinite number of heat exchangers (feedwater heaters), as shown on the $T-s$ diagram.

10-47E Feedwater is heated by steam in a feedwater heater of a regenerative Rankine cycle. The ratio of the bleed steam mass flow rate to the inlet feedwater mass flow rate is to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** The device is adiabatic and thus heat transfer is negligible.

Properties From the steam tables (Tables A-4E through A-6E or EES),

$$h_1 \approx h_{f@110^{\circ}\text{F}} = 78.02 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_2 = 20 \text{ psia} \\ T_2 = 250^{\circ}\text{F} \end{array} \right\} h_2 = 1167.2 \text{ Btu/lbm}$$

$$h_3 \approx h_{f@225^{\circ}\text{F}} = 193.32 \text{ Btu/lbm}$$

Analysis We take the mixing chamber as the system, which is a control volume since mass crosses the boundary. The mass and energy balances for this steady-flow system can be expressed in the rate form as

Mass balance:

$$\dot{m}_{\text{in}} - \dot{m}_{\text{out}} = \Delta \dot{m}_{\text{system}} \xrightarrow{\text{no (steady)}} = 0$$

$$\dot{m}_{\text{in}} = \dot{m}_{\text{out}}$$

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$$

Energy balance:

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} \xrightarrow{\text{no (steady)}} = 0$$

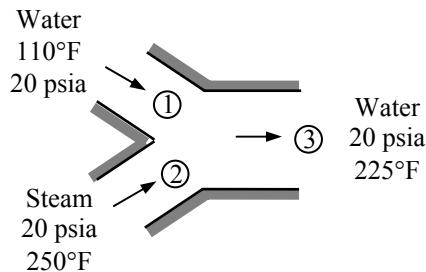

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \quad (\text{since } \dot{Q} = \dot{W} = \Delta \text{ke} \approx \Delta \text{pe} \approx 0)$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = (\dot{m}_1 + \dot{m}_2) h_3$$

Solving for the bleed steam mass flow rate to the inlet feedwater mass flow rate, and substituting gives

$$\frac{\dot{m}_2}{\dot{m}_1} = \frac{h_1 - h_3}{h_3 - h_2} = \frac{(78.02 - 193.32) \text{ kJ/kg}}{(193.32 - 1167.2) \text{ kJ/kg}} = \mathbf{0.118}$$

10-48 In a regenerative Rankine cycle, the closed feedwater heater with a pump as shown in the figure is arranged so that the water at state 5 is mixed with the water at state 2 to form a feedwater which is a saturated liquid. The amount of bleed steam required to heat 1 kg of feedwater is to be determined.

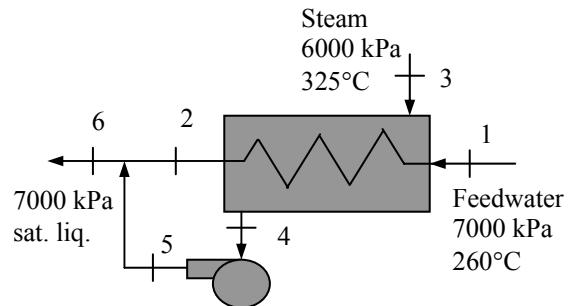

Assumptions 1 This is a steady-flow process since there is no change with time. 2 Kinetic and potential energy changes are negligible. 3 There are no work interactions. 4 The device is adiabatic and thus heat transfer is negligible.

Properties From the steam tables (Tables A-4 through A-6),

$$\left. \begin{array}{l} P_1 = 7000 \text{ kPa} \\ T_1 = 260^\circ\text{C} \end{array} \right\} h_1 \equiv h_f @ 260^\circ\text{C} = 1134.8 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 6000 \text{ kPa} \\ T_3 = 325^\circ\text{C} \end{array} \right\} h_3 = 2969.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 7000 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = h_f @ 7000 \text{ kPa} = 1267.5 \text{ kJ/kg}$$

Analysis We take the entire unit as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}^{\text{sh0 (steady)}}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 + \dot{m}_3 w_{P,\text{in}} = \dot{m}_6 h_6$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 + \dot{m}_3 w_{P,\text{in}} = (\dot{m}_1 + \dot{m}_3) h_6$$

Solving this for \dot{m}_3 ,

$$\dot{m}_3 = \dot{m}_1 \frac{h_6 - h_1}{(h_3 - h_6) + w_{P,\text{in}}} = (1 \text{ kg/s}) \frac{1267.5 - 1134.8}{2969.5 - 1267.5 + 1.319} = \mathbf{0.0779 \text{ kg/s}}$$

where

$$\begin{aligned} w_{P,\text{in}} &= v_4(P_5 - P_4) = v_f @ 6000 \text{ kPa} (P_5 - P_4) \\ &= (0.001319 \text{ m}^3/\text{kg})(7000 - 6000) \text{ kPa} \left(\frac{1 \text{ kPa}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 1.319 \text{ kJ/kg} \end{aligned}$$

10-49E An ideal regenerative Rankine cycle with an open feedwater heater is considered. The work produced by the turbine, the work consumed by the pumps, and the heat rejected in the condenser are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 5 \text{ psia} = 130.18 \text{ Btu/lbm}$$

$$v_1 = v_f @ 5 \text{ psia} = 0.01641 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{\text{PI,in}} &= v_1(P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lrbm})(40 - 5) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.11 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{\text{PI,in}} = 130.18 + 0.11 = 130.29 \text{ Btu/lbm}$$

$$h_3 = h_f @ 40 \text{ psia} = 236.14 \text{ Btu/lbm}$$

$$v_3 = v_f @ 40 \text{ psia} = 0.01715 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{\text{PII,in}} &= v_3(P_4 - P_3) \\ &= (0.01715 \text{ ft}^3/\text{lrbm})(500 - 40) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 1.46 \text{ Btu/lbm} \end{aligned}$$

$$h_4 = h_3 + w_{\text{PII,in}} = 236.14 + 1.46 = 237.60 \text{ Btu/lbm}$$

$$\begin{cases} P_5 = 500 \text{ psia} \\ T_5 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_5 = 1298.6 \text{ Btu/lbm} \\ s_5 = 1.5590 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_6 = 40 \text{ psia} \\ s_6 = s_5 \end{cases} \quad \begin{cases} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{1.5590 - 0.39213}{1.28448} = 0.9085 \\ h_6 = h_f + x_6 h_{fg} = 236.14 + (0.9085)(933.69) = 1084.4 \text{ Btu/lbm} \end{cases}$$

$$\begin{cases} P_7 = 5 \text{ psia} \\ s_7 = s_5 \end{cases} \quad \begin{cases} x_7 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5590 - 0.23488}{1.60894} = 0.8230 \\ h_7 = h_f + x_7 h_{fg} = 130.18 + (0.8230)(1000.5) = 953.63 \text{ Btu/lbm} \end{cases}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heater. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{steady}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1-y) h_2 = 1 h_3$$

where y is the fraction of steam extracted ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{236.14 - 130.29}{1084.4 - 130.29} = 0.1109$$

Then,

$$w_{\text{T,out}} = h_5 - h_6 + (1-y)(h_6 - h_7) = 1298.6 - 1084.4 + (1 - 0.1109)(1084.4 - 953.63) = \mathbf{330.5 \text{ Btu/lbm}}$$

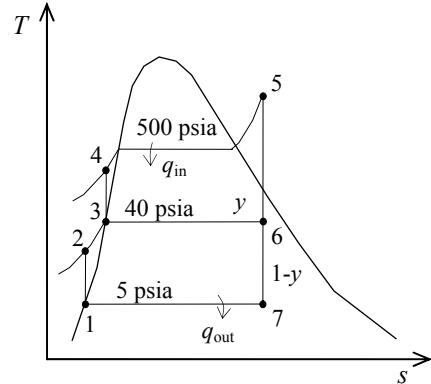

$$w_{\text{P,in}} = w_{\text{PI,in}} + w_{\text{PII,in}} = 0.11 + 1.46 = \mathbf{1.57 \text{ Btu/lbm}}$$

$$q_{\text{out}} = (1-y)(h_7 - h_1) = (1 - 0.1109)(953.63 - 130.18) = \mathbf{732.1 \text{ Btu/lbm}}$$

Also,

$$q_{\text{in}} = h_5 - h_4 = 1298.6 - 237.60 = 1061 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{732.1}{1061} = 0.3100$$

10-50E An ideal regenerative Rankine cycle with an open feedwater heater is considered. The change in thermal efficiency when the steam supplied to the open feedwater heater is at 60 psia rather than 40 psia is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_{f@5\text{ psia}} = 130.18 \text{ Btu/lbm}$$

$$v_1 = v_{f@5\text{ psia}} = 0.01641 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{\text{PI,in}} &= v_1(P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lrbm})(60 - 5)\text{psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.17 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{\text{p,in}} = 130.18 + 0.17 = 130.35 \text{ Btu/lbm}$$

$$h_3 = h_{f@60\text{ psia}} = 262.20 \text{ Btu/lbm}$$

$$v_3 = v_{f@60\text{ psia}} = 0.01738 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{\text{PII,in}} &= v_3(P_4 - P_3) \\ &= (0.01738 \text{ ft}^3/\text{lrbm})(500 - 60)\text{psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 1.42 \text{ Btu/lbm} \end{aligned}$$

$$h_4 = h_3 + w_{\text{p,in}} = 262.20 + 1.42 = 263.62 \text{ Btu/lbm}$$

$$\begin{cases} P_5 = 500 \text{ psia} \\ T_5 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_5 = 1298.6 \text{ Btu/lbm} \\ s_5 = 1.5590 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_6 = 60 \text{ psia} \\ s_6 = s_5 \end{cases} \quad \begin{cases} x_6 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5590 - 0.42728}{1.21697} = 0.9300 \\ h_6 = h_f + x_6 h_{fg} = 262.20 + (0.9300)(915.61) = 1113.7 \text{ Btu/lbm} \end{cases}$$

$$\begin{cases} P_7 = 5 \text{ psia} \\ s_7 = s_5 \end{cases} \quad \begin{cases} x_7 = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5590 - 0.23488}{1.60894} = 0.8230 \\ h_7 = h_f + x_7 h_{fg} = 130.18 + (0.8230)(1000.5) = 953.63 \text{ Btu/lbm} \end{cases}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heater.

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{steady}} 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1-y) h_2 = h_3$$

where y is the fraction of steam extracted ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{262.20 - 130.35}{1113.7 - 130.35} = 0.1341$$

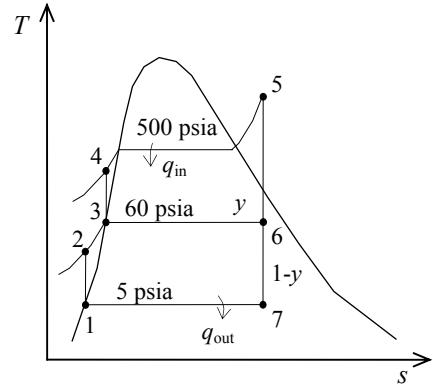

Then,

$$q_{\text{in}} = h_5 - h_4 = 1298.6 - 263.62 = 1035 \text{ Btu/lbm}$$

$$q_{\text{out}} = (1-y)(h_7 - h_1) = (1-0.1341)(953.63 - 130.18) = 713.0 \text{ Btu/lbm}$$

$$\text{and } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{713.0}{1035} = \mathbf{0.3111}$$

When the reheat pressure is increased from 40 psia to 60 psia, the thermal efficiency increases from **0.3100** to **0.3111**, which is an increase of **0.35%**.

10-51E The optimum bleed pressure for the open feedwater heater that maximizes the thermal efficiency of the cycle is to be determined by EES.

10-52 A steam power plant operates on an ideal regenerative Rankine cycle with two open feedwater heaters. The net power output of the power plant and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 5 \text{ kPa} = 137.75 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 5 \text{ kPa} = 0.001005 \text{ m}^3/\text{kg}$$

$$w_{pI,in} = \nu_1 (P_2 - P_1) = (0.001005 \text{ m}^3/\text{kg})(200 - 5 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.20 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,in} = 137.75 + 0.20 = 137.95 \text{ kJ/kg}$$

$$P_3 = 0.2 \text{ MPa} \quad \left\{ \begin{array}{l} h_3 = h_f @ 0.2 \text{ MPa} = 504.71 \text{ kJ/kg} \\ \text{sat.liquid} \end{array} \right.$$

$$\nu_3 = \nu_f @ 0.2 \text{ MPa} = 0.001061 \text{ m}^3/\text{kg}$$

$$w_{pII,in} = \nu_3 (P_4 - P_3) = (0.001061 \text{ m}^3/\text{kg})(600 - 200 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.42 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII,in} = 504.71 + 0.42 = 505.13 \text{ kJ/kg}$$

$$P_5 = 0.6 \text{ MPa} \quad \left\{ \begin{array}{l} h_5 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \text{sat.liquid} \end{array} \right.$$

$$\nu_5 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

$$w_{pIII,in} = \nu_5 (P_6 - P_5) = (0.001101 \text{ m}^3/\text{kg})(10,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 10.35 \text{ kJ/kg}$$

$$h_6 = h_5 + w_{pIII,in} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$P_7 = 10 \text{ MPa} \quad \left\{ \begin{array}{l} h_7 = 3625.8 \text{ kJ/kg} \\ T_7 = 600^\circ\text{C} \end{array} \right.$$

$$s_7 = 6.9045 \text{ kJ/kg} \cdot \text{K}$$

$$P_8 = 0.6 \text{ MPa} \quad \left\{ \begin{array}{l} h_8 = 2821.8 \text{ kJ/kg} \\ s_8 = s_7 \end{array} \right.$$

$$P_9 = 0.2 \text{ MPa} \quad \left\{ \begin{array}{l} x_9 = \frac{s_9 - s_f}{s_{fg}} = \frac{6.9045 - 1.5302}{5.5968} = 0.9602 \\ s_9 = s_7 \end{array} \right.$$

$$h_9 = h_f + x_9 h_{fg} = 504.71 + (0.9602)(2201.6) = 2618.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{10} = 5 \text{ kPa} \\ s_{10} = s_7 \end{array} \right\} x_{10} = \frac{s_{10} - s_f}{s_{fg}} = \frac{6.9045 - 0.4762}{7.9176} = 0.8119$$

$$h_{10} = h_f + x_{10}h_{fg} = 137.75 + (0.8119)(2423.0) = 2105.0 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

FWH-2:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{0 (steady)}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_4 h_4 = \dot{m}_5 h_5 \longrightarrow y h_8 + (1-y) h_4 = l(h_5)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_8 / \dot{m}_5$). Solving for y ,

$$y = \frac{h_5 - h_4}{h_8 - h_4} = \frac{670.38 - 505.13}{2821.8 - 505.13} = 0.07133$$

FWH-1:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_9 h_9 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow z h_9 + (1-y-z) h_2 = (1-y) h_3$$

where z is the fraction of steam extracted from the turbine ($= \dot{m}_9 / \dot{m}_5$) at the second stage. Solving for z ,

$$z = \frac{h_3 - h_2}{h_9 - h_2} (1-y) = \frac{504.71 - 137.95}{2618.7 - 137.95} (1 - 0.07136) = 0.1373$$

Then,

$$q_{\text{in}} = h_7 - h_6 = 3625.8 - 680.73 = 2945.0 \text{ kJ/kg}$$

$$q_{\text{out}} = (1-y-z)(h_{10} - h_1) = (1 - 0.07133 - 0.1373)(2105.0 - 137.75) = 1556.8 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2945.0 - 1556.8 = 1388.2 \text{ kJ/kg}$$

and

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (22 \text{ kg/s})(1388.2 \text{ kJ/kg}) = 30,540 \text{ kW} \cong \mathbf{30.5 \text{ MW}}$$

(b) The thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1556.8 \text{ kJ/kg}}{2945.0 \text{ kJ/kg}} = \mathbf{47.1\%}$$

10-53 An ideal regenerative Rankine cycle with a closed feedwater heater is considered. The work produced by the turbine, the work consumed by the pumps, and the heat added in the boiler are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{p,in} = v_1(P_2 - P_1)$$

$$= (0.001017 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 3.03 \text{ kJ/kg}$$

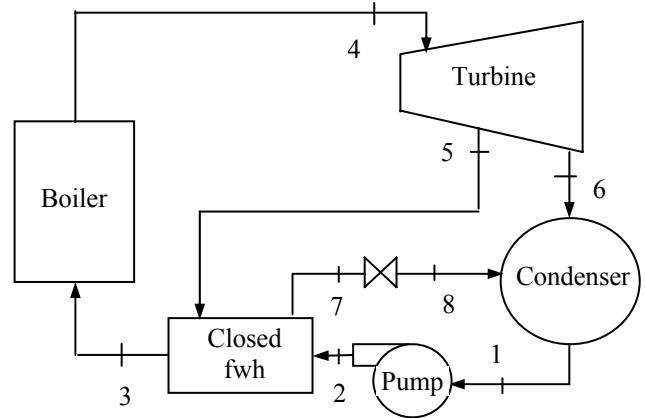

$$h_2 = h_1 + w_{p,in} = 251.42 + 3.03 = 254.45 \text{ kJ/kg}$$

$$P_4 = 3000 \text{ kPa} \quad \left\{ \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ T_4 = 350^\circ\text{C} \end{array} \right. \quad s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K}$$

$$P_5 = 1000 \text{ kPa} \quad \left\{ \begin{array}{l} h_5 = 2851.9 \text{ kJ/kg} \\ s_5 = s_4 \end{array} \right.$$

$$P_6 = 20 \text{ kPa} \quad \left\{ \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ s_6 = s_4 \end{array} \right.$$

$$h_6 = h_f + x_6 h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$P_7 = 1000 \text{ kPa} \quad \left\{ \begin{array}{l} h_7 = 762.51 \text{ kJ/kg} \\ x_7 = 0 \end{array} \right. \quad T_7 = 179.9^\circ\text{C}$$

$$h_8 = h_7 = 762.51 \text{ kJ/kg}$$

$$P_3 = 3000 \text{ kPa} \quad \left\{ \begin{array}{l} h_3 = 763.53 \text{ kJ/kg} \\ T_3 = T_7 = 209.9^\circ\text{C} \end{array} \right.$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ($= \dot{m}_5 / \dot{m}_4$) for closed feedwater heater:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_5 h_5 + \dot{m}_2 h_2 = \dot{m}_3 h_3 + \dot{m}_7 h_7$$

$$y h_5 + 1 h_2 = 1 h_3 + y h_7$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 254.45}{2851.9 - 762.51} = 0.2437$$

Then,

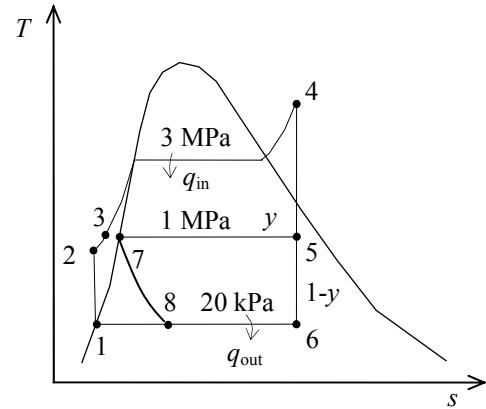

$$w_{T,out} = h_4 - h_5 + (1-y)(h_5 - h_6) = 3116.1 - 2851.9 + (1-0.2437)(2851.9 - 2221.7) = 740.9 \text{ kJ/kg}$$

$$w_{p,in} = 3.03 \text{ kJ/kg}$$

$$q_{in} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also, $w_{net} = w_{T,out} - w_{p,in} = 740.9 - 3.03 = 737.8 \text{ kJ/kg}$

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{737.8}{2353} = 0.3136$$

10-54 Problem 10-53 is reconsidered. The optimum bleed pressure for the open feedwater heater that maximizes the thermal efficiency of the cycle is to be determined by EES.

Analysis The EES program used to solve this problem as well as the solutions are given below.

10-55 A regenerative Rankine cycle with a closed feedwater heater is considered. The thermal efficiency is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_{f@20\text{ kPa}} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@20\text{ kPa}} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(3000 - 20)\text{kPa} \left(\frac{1\text{kJ}}{1\text{kPa} \cdot \text{m}^3} \right) \\ &= 3.03 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 3.03 = 254.45 \text{ kJ/kg}$$

$$\begin{cases} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{cases} \quad \begin{cases} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_5 = 1000 \text{ kPa} \\ s_{5s} = s_4 \end{cases} \quad \begin{cases} h_{5s} = 2851.9 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_6 = 20 \text{ kPa} \\ s_{6s} = s_4 \end{cases} \quad \begin{cases} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_{6s} = h_f + x_{6s} h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{cases}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \rightarrow h_5 = h_4 - \eta_T(h_4 - h_{5s}) = 3116.1 - (0.90)(3116.1 - 2851.9) = 2878.3 \text{ kJ/kg}$$

$$\eta_T = \frac{h_4 - h_6}{h_4 - h_{6s}} \rightarrow h_6 = h_4 - \eta_T(h_4 - h_{6s}) = 3116.1 - (0.90)(3116.1 - 2221.7) = 2311.1 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\begin{cases} P_7 = 1000 \text{ kPa} \\ x_7 = 0 \end{cases} \quad \begin{cases} h_7 = 762.51 \text{ kJ/kg} \\ T_7 = 179.9^\circ\text{C} \end{cases}$$

$$\begin{cases} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 209.9^\circ\text{C} \end{cases} \quad \begin{cases} h_3 = 763.53 \text{ kJ/kg} \end{cases}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ($= \dot{m}_5 / \dot{m}_4$) for closed feedwater heater:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_5 h_5 + \dot{m}_2 h_2 = \dot{m}_3 h_3 + \dot{m}_7 h_7$$

$$y h_5 + 1 h_2 = 1 h_3 + y h_7$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 254.45}{2878.3 - 762.51} = 0.2406$$

Then,

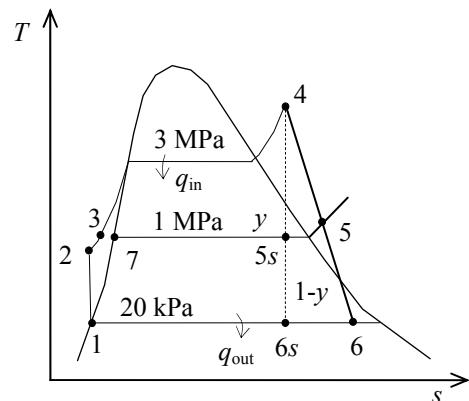

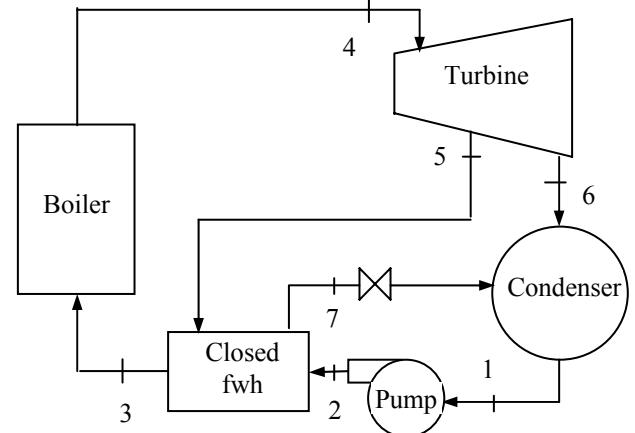

$$w_{T,\text{out}} = h_4 - h_5 + (1-y)(h_5 - h_6) = 3116.1 - 2878.3 + (1-0.2406)(2878.3 - 2311.1) = 668.5 \text{ kJ/kg}$$

$$w_{p,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also, $w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 668.5 - 3.03 = 665.5 \text{ kJ/kg}$

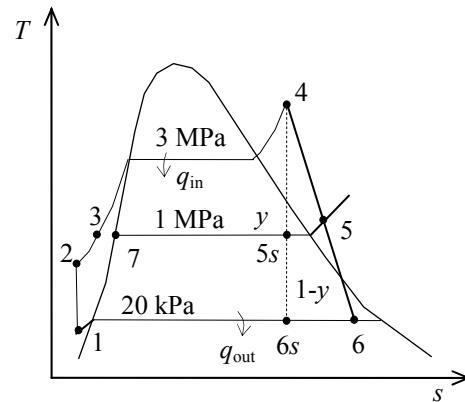

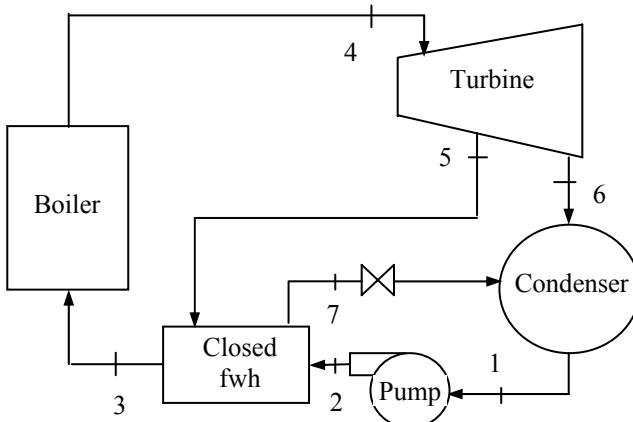

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{665.5}{2353} = 0.2829 = \mathbf{28.3\%}$$

10-56 A regenerative Rankine cycle with a closed feedwater heater is considered. The thermal efficiency is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6 or EES),

When the liquid enters the pump 10°C cooler than a saturated liquid at the condenser pressure, the enthalpies become

$$\left. \begin{array}{l} P_1 = 20 \text{ kPa} \\ T_1 = T_{\text{sat}} @ 20 \text{ kPa} - 10 = 60.06 - 10 \approx 50^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 \approx h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg} \\ v_1 \approx v_f @ 50^\circ\text{C} = 0.001012 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001012 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.02 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 209.34 + 3.02 = 212.36 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 1000 \text{ kPa} \\ s_{5s} = s_4 \end{array} \right\} h_{5s} = 2851.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_{6s} = s_4 \end{array} \right\} \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_{6s} = h_f + x_{6s} h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T(h_4 - h_{5s}) = 3116.1 - (0.90)(3116.1 - 2851.9) = 2878.3 \text{ kJ/kg}$$

$$\eta_T = \frac{h_4 - h_6}{h_4 - h_{6s}} \longrightarrow h_6 = h_4 - \eta_T(h_4 - h_{6s}) = 3116.1 - (0.90)(3116.1 - 2221.7) = 2311.1 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{array}{l} P_7 = 1000 \text{ kPa} \\ x_7 = 0 \end{array} \right\} \begin{array}{l} h_7 = 762.51 \text{ kJ/kg} \\ T_7 = 179.9^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 179.9^\circ\text{C} \end{array} \right\} h_3 = 763.53 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ($= \dot{m}_5 / \dot{m}_4$) for closed feedwater heater:

$$\begin{aligned}\sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_5 h_5 + \dot{m}_2 h_2 &= \dot{m}_3 h_3 + \dot{m}_7 h_7 \\ yh_5 + 1h_2 &= 1h_3 + yh_7\end{aligned}$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 212.36}{2878.3 - 762.51} = 0.2605$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1-y)(h_5 - h_6) = 3116.1 - 2878.3 + (1-0.2605)(2878.3 - 2311.1) = 657.2 \text{ kJ/kg}$$

$$w_{P,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also,

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 657.2 - 3.03 = 654.2 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{654.2}{2353} = \mathbf{0.2781}$$

10-57 The effect of pressure drop and non-isentropic turbine on the rate of heat input is to be determined for a given power plant.

Analysis The EES program used to solve this problem as well as the solutions are given below.

w_p_in=3.031 [m^3-kPa/kg]	w_T_out=668.1 [kJ/kg]
y=0.2405	

Solution without any pressure drop in the boiler:

DELTAP_boiler=0 [kPa]	eta_T=1
Eta_th=0.3136	Fluid\$='steam_iapws'
P[3]=3000 [kPa]	P[4]=3000 [kPa]
q_in=2352.5 [kJ/kg]	w_net=737.8 [kJ/kg]
w_p_in=3.031 [m^3-kPa/kg]	w_T_out=740.9 [kJ/kg]
y=0.2437	

10-58 A steam power plant operates on an ideal regenerative Rankine cycle with two feedwater heaters, one closed and one open. The mass flow rate of steam through the boiler for a net power output of 400 MW and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{f@10\text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(600 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.60 \text{ kJ/kg} \\ h_2 &= h_1 + w_{pI,\text{in}} = 191.81 + 0.60 = 192.40 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} P_3 &= 0.6 \text{ MPa} \quad \left\{ \begin{array}{l} h_3 = h_{f@0.3\text{ MPa}} = 670.38 \text{ kJ/kg} \\ \text{sat. liquid} \quad v_3 = v_{f@0.3\text{ MPa}} = 0.001101 \text{ m}^3/\text{kg} \end{array} \right. \\ w_{pII,\text{in}} &= v_3(P_4 - P_3) \end{aligned}$$

$$\begin{aligned} &= (0.001101 \text{ m}^3/\text{kg})(10000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.35 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII,\text{in}} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$\begin{aligned} P_6 &= 1.2 \text{ MPa} \quad \left\{ \begin{array}{l} h_6 = h_7 = h_{f@1.2\text{ MPa}} = 798.33 \text{ kJ/kg} \\ \text{sat. liquid} \quad T_6 = T_{\text{sat}@1.2\text{ MPa}} = 188.0^\circ\text{C} \end{array} \right. \end{aligned}$$

$$T_6 = T_5, \quad P_5 = 10 \text{ MPa} \rightarrow h_5 = 798.33 \text{ kJ/kg}$$

$$P_8 = 10 \text{ MPa} \quad \left\{ \begin{array}{l} h_8 = 3625.8 \text{ kJ/kg} \\ T_8 = 600^\circ\text{C} \quad s_8 = 6.9045 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \end{math>$$

$$\begin{aligned} P_9 &= 1.2 \text{ MPa} \quad \left\{ \begin{array}{l} h_9 = 2974.5 \text{ kJ/kg} \\ s_9 = s_8 \end{array} \right. \end{aligned}$$

$$\begin{aligned} P_{10} &= 0.6 \text{ MPa} \quad \left\{ \begin{array}{l} h_{10} = 2820.9 \text{ kJ/kg} \\ s_{10} = s_8 \end{array} \right. \end{aligned}$$

$$\begin{aligned} P_{11} &= 10 \text{ kPa} \quad \left\{ \begin{array}{l} x_{11} = \frac{s_{11} - s_f}{s_{fg}} = \frac{6.9045 - 0.6492}{7.4996} = 0.8341 \\ s_{11} = s_8 \quad h_{11} = h_f + x_{11}h_{fg} = 191.81 + (0.8341)(2392.1) = 2187.0 \text{ kJ/kg} \end{array} \right. \end{aligned}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

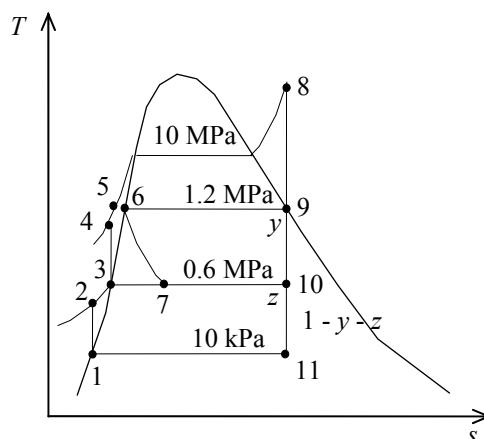

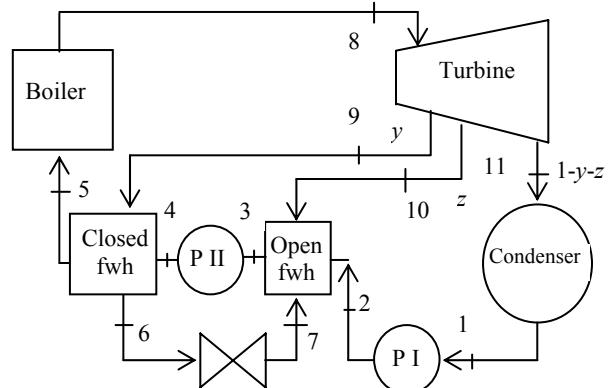

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{(steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_9(h_9 - h_6) = \dot{m}_5(h_5 - h_4) \longrightarrow y(h_9 - h_6) = (h_5 - h_4)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_{10} / \dot{m}_5$). Solving for y ,

$$y = \frac{h_5 - h_4}{h_9 - h_6} = \frac{798.33 - 680.73}{2974.5 - 798.33} = 0.05404$$

For the open FWH,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_7 h_7 + \dot{m}_2 h_2 + \dot{m}_{10} h_{10} = \dot{m}_3 h_3 \longrightarrow y h_7 + (1-y-z) h_2 + z h_{10} = (1) h_3$$

where z is the fraction of steam extracted from the turbine ($= \dot{m}_9 / \dot{m}_5$) at the second stage. Solving for z ,

$$z = \frac{(h_3 - h_2) - y(h_7 - h_2)}{h_{10} - h_2} = \frac{670.38 - 192.40 - (0.05404)(798.33 - 192.40)}{2820.9 - 192.40} = 0.1694$$

Then,

$$q_{\text{in}} = h_8 - h_5 = 3625.8 - 798.33 = 2827 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y - z)(h_{11} - h_1) = (1 - 0.05404 - 0.1694)(2187.0 - 191.81) = 1549 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2827 - 1549 = 1278 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{400,000 \text{ kJ/s}}{1278 \text{ kJ/kg}} = \mathbf{313.0 \text{ kg/s}}$$

$$(b) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1549 \text{ kJ/kg}}{2827 \text{ kJ/kg}} = 0.452 = \mathbf{45.2\%}$$

10-59 Problem 10-58 is reconsidered. The effects of turbine and pump efficiencies on the mass flow rate and thermal efficiency are to be investigated. Also, the *T-s* diagram is to be plotted.

10-60 A steam power plant that operates on an ideal regenerative Rankine cycle with a closed feedwater heater is considered. The temperature of the steam at the inlet of the closed feedwater heater, the mass flow rate of the steam extracted from the turbine for the closed feedwater heater, the net power output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1)/\eta_p \\ &= (0.001017 \text{ m}^3/\text{kg})(8000 - 20 \text{ kPa})/0.88 \\ &= 9.22 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} h_2 &= h_1 + w_{pI,in} \\ &= 251.42 + 9.223 \\ &= 260.65 \text{ kJ/kg} \end{aligned}$$

$$\begin{cases} P_3 = 1 \text{ MPa} \\ \text{sat. liquid} \end{cases} \begin{cases} h_3 = h_f @ 1 \text{ MPa} = 762.51 \text{ kJ/kg} \\ v_3 = v_f @ 1 \text{ MPa} = 0.001127 \text{ m}^3/\text{kg} \end{cases}$$

$$\begin{aligned} w_{pII,in} &= v_3(P_{11} - P_3)/\eta_p \\ &= (0.001127 \text{ m}^3/\text{kg})(8000 - 1000 \text{ kPa})/0.88 \\ &= 8.97 \text{ kJ/kg} \end{aligned}$$

$$h_{11} = h_3 + w_{pII,in} = 762.51 + 8.97 = 771.48 \text{ kJ/kg}$$

Also, $h_4 = h_{10} = h_{11} = 771.48 \text{ kJ/kg}$ since the two fluid streams which are being mixed have the same enthalpy.

$$\begin{cases} P_5 = 8 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{cases} \begin{cases} h_5 = 3399.5 \text{ kJ/kg} \\ s_5 = 6.7266 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_6 = 3 \text{ MPa} \\ s_6 = s_5 \end{cases} \begin{cases} h_{6s} = 3104.7 \text{ kJ/kg} \end{cases}$$

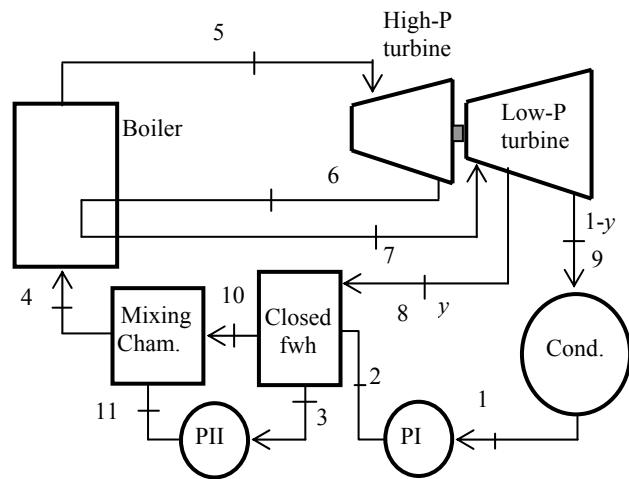

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) \\ &= 3399.5 - (0.88)(3399.5 - 3104.7) = 3140.1 \text{ kJ/kg} \end{aligned}$$

$$\begin{cases} P_7 = 3 \text{ MPa} \\ T_7 = 500^\circ\text{C} \end{cases} \begin{cases} h_7 = 3457.2 \text{ kJ/kg} \\ s_7 = 7.2359 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_8 = 1 \text{ MPa} \\ s_8 = s_7 \end{cases} \begin{cases} h_{8s} = 3117.1 \text{ kJ/kg} \end{cases}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} \longrightarrow h_8 = h_7 - \eta_T(h_7 - h_{8s}) \\ &= 3457.2 - (0.88)(3457.2 - 3117.1) = 3157.9 \text{ kJ/kg} \end{aligned}$$

$$\begin{cases} P_8 = 1 \text{ MPa} \\ h_8 = 3157.9 \text{ kJ/kg} \end{cases} \begin{cases} T_8 = 349.9^\circ\text{C} \end{cases}$$

$$\left. \begin{array}{l} P_9 = 20 \text{ kPa} \\ s_9 = s_7 \end{array} \right\} h_{9s} = 2385.2 \text{ kJ/kg}$$

$$\eta_T = \frac{h_7 - h_9}{h_7 - h_{9s}} \longrightarrow h_9 = h_7 - \eta_T(h_7 - h_{9s})$$

$$= 3457.2 - (0.88)(3457.2 - 2385.2) = 2513.9 \text{ kJ/kg}$$

The fraction of steam extracted from the low pressure turbine for closed feedwater heater is determined from the steady-flow energy balance equation applied to the feedwater heater. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$(1-y)(h_{10} - h_2) = y(h_8 - h_3)$$

$$(1-y)(771.48 - 260.65) = y(3157.9 - 762.51) \longrightarrow y = 0.1758$$

The corresponding mass flow rate is

$$\dot{m}_8 = y\dot{m}_5 = (0.1758)(15 \text{ kg/s}) = \mathbf{2.637 \text{ kg/s}}$$

(c) Then,

$$q_{\text{in}} = h_5 - h_4 + h_7 - h_6 = 3399.5 - 771.48 + 3457.2 - 3140.1 = 2945.2 \text{ kJ/kg}$$

$$q_{\text{out}} = (1-y)(h_9 - h_1) = (1-0.1758)(2513.9 - 251.42) = 1864.8 \text{ kJ/kg}$$

and

$$\dot{W}_{\text{net}} = \dot{m}(q_{\text{in}} - q_{\text{out}}) = (15 \text{ kg/s})(2945.8 - 1864.8) \text{ kJ/kg} = \mathbf{16,206 \text{ kW}}$$

(b) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1864.8 \text{ kJ/kg}}{2945.8 \text{ kJ/kg}} = 0.3668 = \mathbf{36.7\%}$$

10-61 A Rankine steam cycle modified with two closed feedwater heaters is considered. The $T-s$ diagram for the ideal cycle is to be sketched. The fraction of mass extracted for the closed feedwater heater z and the cooling water flow rate are to be determined. Also, the net power output and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 20 \text{ kPa} = 251 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.00102 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pl,in}} &= v_1(P_2 - P_1) \\ &= (0.00102 \text{ m}^3/\text{kg})(5000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.1 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 251 + 5.1 = 256.1 \text{ kJ/kg}$$

Also,

$$h_3 = h_{11} = h_f @ 245 \text{ kPa} = 533 \text{ kJ/kg}$$

$h_{12} = h_{11}$ (throttle valve operation)

$$h_4 = h_9 = h_f @ 1400 \text{ kPa} = 830 \text{ kJ/kg}$$

$h_{10} = h_9$ (throttle valve operation)

An energy balance on the closed feedwater heater gives

$$1h_2 + zh_7 + yh_{10} = 1h_3 + (y+z)h_{11}$$

where z is the fraction of steam extracted from the low-pressure turbine. Solving for z ,

$$z = \frac{(h_3 - h_2) + y(h_{11} - h_{10})}{h_7 - h_{11}} = \frac{(533 - 256.1) + (0.1153)(533 - 830)}{2918 - 533} = 0.1017$$

(c) An energy balance on the condenser gives

$$\dot{m}_8 h_8 + \dot{m}_w h_{w1} + \dot{m}_{12} h_{12} = \dot{m}_1 h_1 + \dot{m}_w h_{w2}$$

$$\dot{m}_w (h_{w2} - h_{w1}) = \dot{m}_8 h_8 + \dot{m}_{12} h_{12} - \dot{m}_1 h_1$$

Solving for the mass flow rate of cooling water, and substituting with correct units,

$$\begin{aligned} \dot{m}_w &= \frac{\dot{m}_8 [(1 - y - z)h_8 + (y + z)h_{12} - 1h_1]}{c_{pw}\Delta T_w} \\ &= \frac{(50)[(1 - 0.1153 - 0.1017)(2477) + (0.1153 + 0.1017)(533) - 1(251)]}{(4.18)(10)} \\ &= 2158 \text{ kg/s} \end{aligned}$$

(d) The work output from the turbines is

$$\begin{aligned} w_{T,\text{out}} &= h_5 - yh_6 - zh_7 - (1 - y - z)h_8 \\ &= 3900 - (0.1153)(3406) - (0.1017)(2918) - (1 - 0.1153 - 0.1017)(2477) \\ &= 1271 \text{ kJ/kg} \end{aligned}$$

The net work output from the cycle is

$$\begin{aligned} w_{\text{net}} &= w_{T,\text{out}} - w_{P,\text{in}} \\ &= 1271 - 5.1 = 1265.9 \text{ kJ/kg} \end{aligned}$$

The net power output is

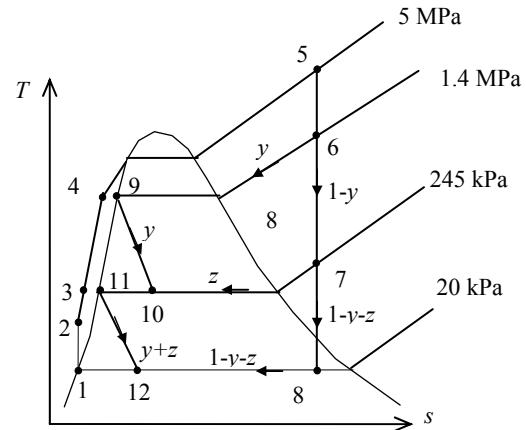

$$\dot{W}_{\text{net}} = \dot{m}w_{\text{net}} = (50 \text{ kg/s})(1265.9 \text{ kJ/kg}) = 63,300 \text{ kW} = 63.3 \text{ MW}$$

The rate of heat input in the boiler is

$$\dot{Q}_{\text{in}} = \dot{m}(h_5 - h_4) = (50 \text{ kg/s})(3900 - 830) \text{ kJ/kg} = 153,500 \text{ kW}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{63,300 \text{ kW}}{153,500 \text{ kW}} = 0.412 = 41.2\%$$

Second-Law Analysis of Vapor Power Cycles

10-62C In the simple ideal Rankine cycle, irreversibilities occur during heat addition and heat rejection processes in the boiler and the condenser, respectively, and both are due to temperature difference. Therefore, the irreversibilities can be decreased and thus the 2nd law efficiency can be increased by minimizing the temperature differences during heat transfer in the boiler and the condenser. One way of doing that is regeneration.

10-63E The exergy destructions associated with each of the processes of the Rankine cycle described in Prob. 10-17E are to be determined for the specified source and sink temperatures.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Problem 10-17E,

$$s_1 = s_2 = s_f @ 3 \text{ psia} = 0.2009 \text{ Btu/lbm} \cdot \text{R}$$

$$s_3 = s_4 = 1.6413 \text{ Btu/lbm} \cdot \text{R}$$

$$q_{\text{in}} = h_3 - h_2 = 1456.0 - 111.81 = 1344.2 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_1 = 975.24 - 109.40 = 865.8 \text{ Btu/lbm}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

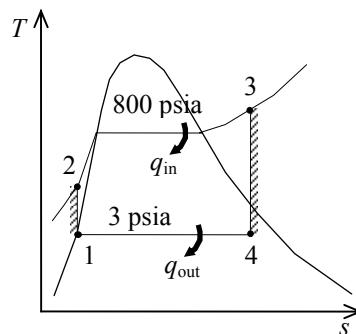

$$x_{\text{destroyed},23} = T_0 \left(s_3 - s_2 - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (500 \text{ R}) \left(1.6413 - 0.2009 - \frac{1344.2 \text{ Btu/lbm}}{1960 \text{ R}} \right) = 377 \text{ Btu/lbm}$$

$$x_{\text{destroyed},41} = T_0 \left(s_1 - s_4 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (500 \text{ R}) \left(0.2009 - 1.6413 + \frac{865.8 \text{ Btu/lbm}}{500 \text{ R}} \right) = 146 \text{ Btu/lbm}$$

Processes 1-2 and 3-4 are isentropic, and thus

$$x_{\text{destroyed},12} = 0$$

$$x_{\text{destroyed},34} = 0$$

10-64 The exergy destruction associated with the heat rejection process in Prob. 10-21 is to be determined for the specified source and sink temperatures. The exergy of the steam at the boiler exit is also to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Problem 10-21,

$$s_1 = s_2 = s_{f@10\text{kPa}} = 0.6492 \text{ kJ/kg}\cdot\text{K}$$

$$s_3 = s_4 = 6.8000 \text{ kJ/kg}\cdot\text{K}$$

$$h_3 = 3411.4 \text{ kJ/kg}$$

$$q_{\text{out}} = 1961.8 \text{ kJ/kg}$$

The exergy destruction associated with the heat rejection process is

$$x_{\text{destroyed},41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = (290 \text{ K}) \left(0.6492 - 6.8000 + \frac{1961.8 \text{ kJ/kg}}{290 \text{ K}} \right) = \mathbf{178.0 \text{ kJ/kg}}$$

The exergy of the steam at the boiler exit is simply the flow exergy,

$$\begin{aligned} \psi_3 &= (h_3 - h_0) - T_0(s_3 - s_0) + \frac{\mathbf{v}_3^2}{2} + qz_3^{g0} \\ &= (h_3 - h_0) - T_0(s_3 - s_0) \end{aligned}$$

where

$$h_0 = h_{@(290 \text{ K}, 100 \text{ kPa})} \cong h_f @ 290 \text{ K} = 71.95 \text{ kJ/kg}$$

$$s_0 = s_{@(290 \text{ K}, 100 \text{ kPa})} \cong s_f @ 290 \text{ K} = 0.2533 \text{ kJ/kg}\cdot\text{K}$$

Thus,

$$\psi_3 = (3411.4 - 71.95) \text{ kJ/kg} - (290 \text{ K})(6.800 - 0.2532) \text{ kJ/kg}\cdot\text{K} = \mathbf{1440.9 \text{ kJ/kg}}$$

10-65 The component of the ideal reheat Rankine cycle described in Prob. 10-33 with the largest exergy destruction is to be identified.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Prob. 10-33,

$$\begin{aligned}s_1 &= s_2 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg}\cdot\text{K} \\ s_3 &= s_4 = 6.5579 \text{ kJ/kg}\cdot\text{K} \\ s_5 &= s_6 = 8.0893 \text{ kJ/kg}\cdot\text{K} \\ q_{\text{in},2-3} &= h_3 - h_2 = 3273.3 - 199.88 = 3073.4 \text{ kJ/kg} \\ q_{\text{in},4-5} &= h_5 - h_4 = 3485.4 - 2636.4 = 848.1 \text{ kJ/kg} \\ q_{\text{out}} &= 2373.1 \text{ kJ/kg}\end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned}x_{\text{destroyed},23} &= T_0 \left(s_3 - s_2 - \frac{q_{\text{in},2-3}}{T_{\text{source}}} \right) = (283 \text{ K}) \left(6.5579 - 0.6492 - \frac{3073.4 \text{ kJ/kg}}{883 \text{ K}} \right) = \mathbf{687.1 \text{ kJ/kg}} \\ x_{\text{destroyed},45} &= T_0 \left(s_5 - s_4 - \frac{q_{\text{in},4-5}}{T_{\text{source}}} \right) = (283 \text{ K}) \left(8.0893 - 6.5579 - \frac{848.1 \text{ kJ/kg}}{883 \text{ K}} \right) = \mathbf{161.6 \text{ kJ/kg}} \\ x_{\text{destroyed},61} &= T_0 \left(s_1 - s_6 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (283 \text{ K}) \left(0.6492 - 8.0893 + \frac{2373.1 \text{ kJ/kg}}{283 \text{ K}} \right) = \mathbf{-267.6 \text{ kJ/kg}}\end{aligned}$$

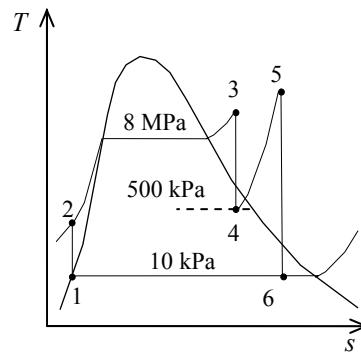

Processes 1-2, 3-4, and 5-6 are isentropic, and thus,

$$x_{\text{destroyed},12} = \mathbf{0}$$

$$x_{\text{destroyed},34} = \mathbf{0}$$

$$x_{\text{destroyed},56} = \mathbf{0}$$

The greatest exergy destruction occurs during heat addition process 2-3.

10-66 The exergy destructions associated with each of the processes of the reheat Rankine cycle described in Prob. 10-35 are to be determined for the specified source and sink temperatures.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Problem 10-35,

$$s_1 = s_2 = s_{f@20\text{kPa}} = 0.8320 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_4 = 6.5432 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = s_6 = 7.1292 \text{ kJ/kg} \cdot \text{K}$$

$$q_{23,\text{in}} = 3178.3 - 257.50 = 2920.8 \text{ kJ/kg}$$

$$q_{45,\text{in}} = 3248.4 - 2901.0 = 347.3 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2349.7 - 251.42 = 2098.3 \text{ kJ/kg}$$

Processes 1-2, 3-4, and 5-6 are isentropic. Thus, $i_{12} = i_{34} = i_{56} = 0$. Also,

$$x_{\text{destroyed},23} = T_0 \left(s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = (295 \text{ K}) \left(6.5432 - 0.8320 + \frac{-2920.8 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{1110 \text{ kJ/kg}}$$

$$x_{\text{destroyed},45} = T_0 \left(s_5 - s_4 + \frac{q_{R,45}}{T_R} \right) = (295 \text{ K}) \left(7.1292 - 6.5432 + \frac{-347.3 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{104.6 \text{ kJ/kg}}$$

$$x_{\text{destroyed},61} = T_0 \left(s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = (295 \text{ K}) \left(0.8320 - 7.1292 + \frac{2098.3 \text{ kJ/kg}}{295 \text{ K}} \right) = \mathbf{240.6 \text{ kJ/kg}}$$

10-67 Problem 10-66 is reconsidered. The problem is to be solved by the diagram window data entry feature of EES by including the effects of the turbine and pump efficiencies. Also, the $T-s$ diagram is to be plotted.

Analysis The problem is solved using EES, and the solution is given below.

10-68E The component of the ideal regenerative Rankine cycle described in Prob. 10-49E with the largest exergy destruction is to be identified.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Prob. 10-49E,

$$s_1 = s_2 = s_f @ 5 \text{ psia} = 0.23488 \text{ Btu/lbm}\cdot\text{R}$$

$$s_3 = s_4 = s_f @ 40 \text{ psia} = 0.39213 \text{ Btu/lbm}\cdot\text{R}$$

$$s_5 = s_6 = s_7 = 1.5590 \text{ Btu/lbm}\cdot\text{R}$$

$$q_{\text{in}} = h_5 - h_4 = 1298.6 - 237.6 = 1061 \text{ kJ/kg}$$

$$q_{\text{out}} = 732.1 \text{ Btu/lbm}$$

$$y = 0.1109$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed},45} = T_0 \left(s_5 - s_4 - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (520 \text{ R}) \left(1.5590 - 0.39213 - \frac{1061 \text{ Btu/lbm}}{1260 \text{ R}} \right) = \mathbf{168.9 \text{ Btu/lbm}}$$

$$x_{\text{destroyed},71} = T_0 \left(s_1 - s_7 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) = (520 \text{ R}) \left(0.23488 - 1.5590 + \frac{732.1 \text{ Btu/lbm}}{520 \text{ R}} \right) = \mathbf{43.6 \text{ Btu/lbm}}$$

For open feedwater heater, we have

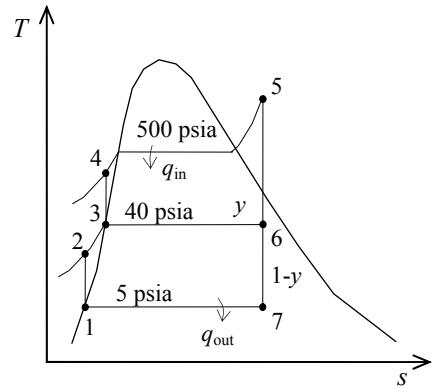

$$\begin{aligned} x_{\text{destroyed,FWH}} &= T_0 [s_3 - y s_6 - (1-y) s_2] \\ &= (520 \text{ R}) [0.39213 - (0.1109)(1.5590) - (1-0.1109)(0.23488)] \\ &= \mathbf{5.4 \text{ Btu/lbm}} \end{aligned}$$

Processes 1-2, 3-4, 5-6, and 6-7 are isentropic, and thus

$$x_{\text{destroyed},12} = \mathbf{0} \quad x_{\text{destroyed},56} = \mathbf{0}$$

$$x_{\text{destroyed},34} = \mathbf{0} \quad x_{\text{destroyed},67} = \mathbf{0}$$

The greatest exergy destruction occurs during heat addition process 4-5.

10-69 A single-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The power output from the turbine, the thermal efficiency of the plant, the exergy of the geothermal liquid at the exit of the flash chamber, and the exergy destructions and exergy efficiencies for the flash chamber, the turbine, and the entire plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4, A-5, and A-6)

$$\begin{aligned} T_1 &= 230^\circ\text{C} \quad h_1 = 990.14 \text{ kJ/kg} \\ x_1 &= 0 \quad s_1 = 2.6100 \text{ kJ/kg.K} \\ P_2 &= 500 \text{ kPa} \quad x_2 = 0.1661 \\ h_2 &= h_1 = 990.14 \text{ kJ/kg} \quad s_2 = 2.6841 \text{ kJ/kg.K} \end{aligned}$$

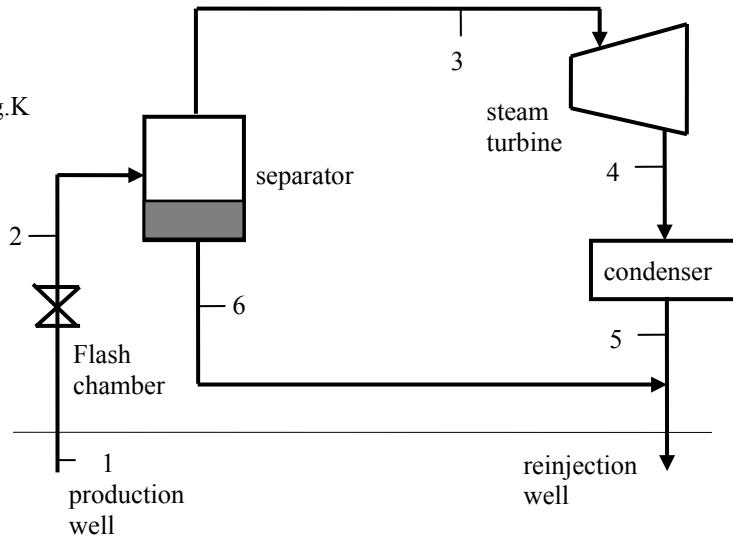

$$\begin{aligned} \dot{m}_3 &= x_2 \dot{m}_1 \\ &= (0.1661)(230 \text{ kg/s}) \\ &= 38.19 \text{ kg/s} \end{aligned}$$

$$\begin{aligned} P_3 &= 500 \text{ kPa} \quad h_3 = 2748.1 \text{ kJ/kg} \\ x_3 &= 1 \quad s_3 = 6.8207 \text{ kJ/kg.K} \end{aligned}$$

$$\begin{aligned} P_4 &= 10 \text{ kPa} \quad h_4 = 2464.3 \text{ kJ/kg} \\ x_4 &= 0.95 \quad s_4 = 7.7739 \text{ kJ/kg.K} \end{aligned}$$

$$\begin{aligned} P_6 &= 500 \text{ kPa} \quad h_6 = 640.09 \text{ kJ/kg} \\ x_6 &= 0 \quad s_6 = 1.8604 \text{ kJ/kg.K} \end{aligned}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 38.19 = 191.81 \text{ kg/s}$$

The power output from the turbine is

$$\dot{W}_T = \dot{m}_3 (h_3 - h_4) = (38.19 \text{ kg})(2748.1 - 2464.3) \text{ kJ/kg} = \mathbf{10,842 \text{ kW}}$$

We use saturated liquid state at the standard temperature for dead state properties

$$\begin{aligned} T_0 &= 25^\circ\text{C} \quad h_0 = 104.83 \text{ kJ/kg} \\ x_0 &= 0 \quad s_0 = 0.3672 \text{ kJ/kg} \end{aligned}$$

$$\dot{E}_{in} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{th} = \frac{\dot{W}_{T,out}}{\dot{E}_{in}} = \frac{10,842}{203,622} = 0.0532 = \mathbf{5.3\%}$$

(b) The specific exergies at various states are

$$\psi_1 = h_1 - h_0 - T_0(s_1 - s_0) = (990.14 - 104.83) \text{ kJ/kg} - (298 \text{ K})(2.6100 - 0.3672) \text{ kJ/kg.K} = 216.53 \text{ kJ/kg}$$

$$\psi_2 = h_2 - h_0 - T_0(s_2 - s_0) = (990.14 - 104.83) \text{ kJ/kg} - (298 \text{ K})(2.6841 - 0.3672) \text{ kJ/kg.K} = 194.44 \text{ kJ/kg}$$

$$\psi_3 = h_3 - h_0 - T_0(s_3 - s_0) = (2748.1 - 104.83) \text{ kJ/kg} - (298 \text{ K})(6.8207 - 0.3672) \text{ kJ/kg.K} = 719.10 \text{ kJ/kg}$$

$$\psi_4 = h_4 - h_0 - T_0(s_4 - s_0) = (2464.3 - 104.83) \text{ kJ/kg} - (298 \text{ K})(7.7739 - 0.3672) \text{ kJ/kg.K} = 151.05 \text{ kJ/kg}$$

$$\psi_6 = h_6 - h_0 - T_0(s_6 - s_0) = (640.09 - 104.83) \text{ kJ/kg} - (298 \text{ K})(1.8604 - 0.3672) \text{ kJ/kg.K} = 89.97 \text{ kJ/kg}$$

The exergy of geothermal water at state 6 is

$$\dot{X}_6 = \dot{m}_6 \psi_6 = (191.81 \text{ kg/s})(89.97 \text{ kJ/kg}) = \mathbf{17,257 \text{ kW}}$$

(c) Flash chamber:

$$\dot{X}_{\text{dest,FC}} = \dot{m}_1(\psi_1 - \psi_2) = (230 \text{ kg/s})(216.53 - 194.44) \text{ kJ/kg} = \mathbf{5080 \text{ kW}}$$

$$\eta_{\text{II,FC}} = \frac{\psi_2}{\psi_1} = \frac{194.44}{216.53} = 0.898 = \mathbf{89.8\%}$$

(d) Turbine:

$$\dot{X}_{\text{dest,T}} = \dot{m}_3(\psi_3 - \psi_4) - \dot{W}_{\text{T}} = (38.19 \text{ kg/s})(719.10 - 151.05) \text{ kJ/kg} - 10,842 \text{ kW} = \mathbf{10,854 \text{ kW}}$$

$$\eta_{\text{II,T}} = \frac{\dot{W}_{\text{T}}}{\dot{m}_3(\psi_3 - \psi_4)} = \frac{10,842 \text{ kW}}{(38.19 \text{ kg/s})(719.10 - 151.05) \text{ kJ/kg}} = 0.500 = \mathbf{50.0\%}$$

(e) Plant:

$$\dot{X}_{\text{in,Plant}} = \dot{m}_1\psi_1 = (230 \text{ kg/s})(216.53 \text{ kJ/kg}) = 49,802 \text{ kW}$$

$$\dot{X}_{\text{dest,Plant}} = \dot{X}_{\text{in,Plant}} - \dot{W}_{\text{T}} = 49,802 - 10,842 = \mathbf{38,960 \text{ kW}}$$

$$\eta_{\text{II,Plant}} = \frac{\dot{W}_{\text{T}}}{\dot{X}_{\text{in,Plant}}} = \frac{10,842 \text{ kW}}{49,802 \text{ kW}} = 0.2177 = \mathbf{21.8\%}$$

Cogeneration

10-70C The utilization factor of a cogeneration plant is the ratio of the energy utilized for a useful purpose to the total energy supplied. It could be unity for a plant that does not produce any power.

10-71C No. A cogeneration plant may involve throttling, friction, and heat transfer through a finite temperature difference, and still have a utilization factor of unity.

10-72C Yes, if the cycle involves no irreversibilities such as throttling, friction, and heat transfer through a finite temperature difference.

10-73C Cogeneration is the production of more than one useful form of energy from the same energy source. Regeneration is the transfer of heat from the working fluid at some stage to the working fluid at some other stage.

10-74 A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The net power produced and the utilization factor of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= \nu_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(600 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.60 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 191.81 + 0.60 = 192.41 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta\dot{E}_{system} \xrightarrow{\text{no (steady)}} 0 \longrightarrow \dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

$$\text{or, } h_4 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(22.50)(192.41) + (7.50)(670.38)}{30} = 311.90 \text{ kJ/kg}$$

$$\nu_4 \approx \nu_f @ h_4 = 311.90 \text{ kJ/kg} = 0.001026 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII,in} &= \nu_4(P_5 - P_4) \\ &= (0.001026 \text{ m}^3/\text{kg})(7000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.57 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII,in} = 311.90 + 6.57 = 318.47 \text{ kJ/kg}$$

$$\begin{cases} P_6 = 7 \text{ MPa} \\ T_6 = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_6 = 3411.4 \text{ kJ/kg} \\ s_6 = 6.8000 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_7 = 0.6 \text{ MPa} \\ s_7 = s_6 \end{cases} \quad \begin{cases} h_7 = 2774.6 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_8 = 10 \text{ kPa} \\ s_8 = s_6 \end{cases} \quad \begin{cases} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{6.8000 - 0.6492}{7.4996} = 0.8201 \\ h_8 = h_f + x_8 h_{fg} = 191.81 + (0.8201)(2392.1) = 2153.6 \text{ kJ/kg} \end{cases}$$

Then,

$$\begin{aligned} \dot{W}_{T,out} &= \dot{m}_6(h_6 - h_7) + \dot{m}_8(h_7 - h_8) \\ &= (30 \text{ kg/s})(3411.4 - 2774.6) \text{ kJ/kg} + (22.5 \text{ kg/s})(2774.6 - 2153.6) \text{ kJ/kg} = 33,077 \text{ kW} \end{aligned}$$

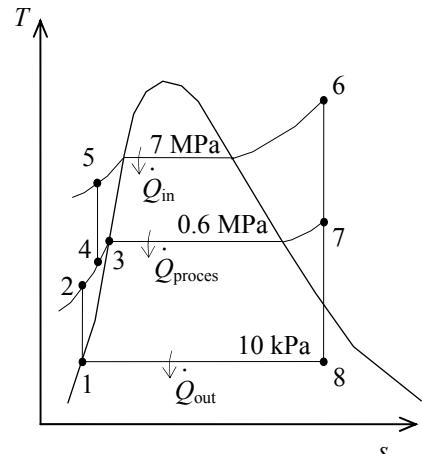

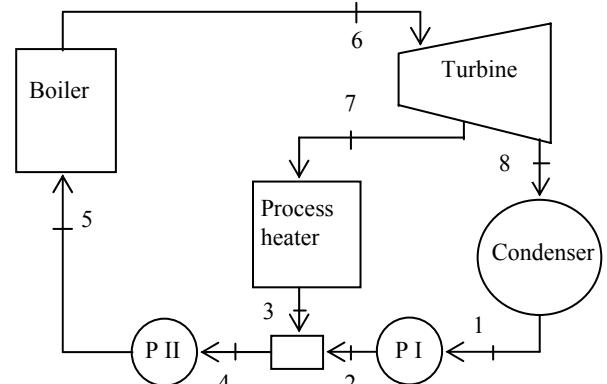

$$\dot{W}_{p,in} = \dot{m}_1 w_{pI,in} + \dot{m}_4 w_{pII,in} = (22.5 \text{ kg/s})(0.60 \text{ kJ/kg}) + (30 \text{ kg/s})(6.57 \text{ kJ/kg}) = 210.6 \text{ kW}$$

$$\dot{W}_{net} = \dot{W}_{T,out} - \dot{W}_{p,in} = 33,077 - 210.6 = \mathbf{32,866 \text{ kW}}$$

$$\text{Also, } \dot{Q}_{process} = \dot{m}_7(h_7 - h_3) = (7.5 \text{ kg/s})(2774.6 - 670.38) \text{ kJ/kg} = 15,782 \text{ kW}$$

$$\dot{Q}_{in} = \dot{m}_5(h_6 - h_5) = (30 \text{ kg/s})(3411.4 - 318.47) = 92,788 \text{ kW}$$

$$\text{and } \varepsilon_u = \frac{\dot{W}_{net} + \dot{Q}_{process}}{\dot{Q}_{in}} = \frac{32,866 + 15,782}{92,788} = \mathbf{52.4\%}$$

10-75E A large food-processing plant requires steam at a relatively high pressure, which is extracted from the turbine of a cogeneration plant. The rate of heat transfer to the boiler and the power output of the cogeneration plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

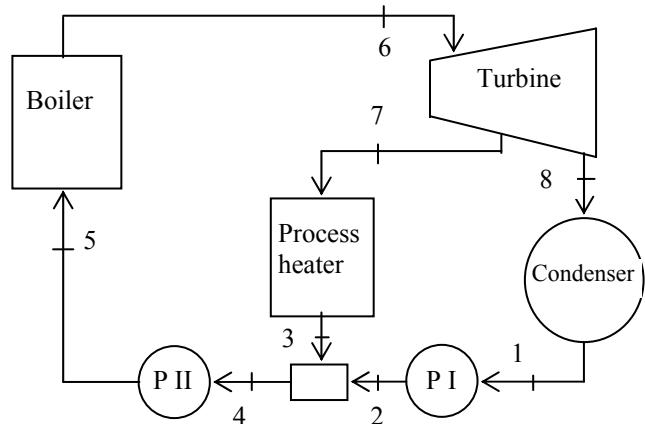

$$h_1 = h_f @ 2 \text{ psia} = 94.02 \text{ Btu/lbm}$$

$$v_1 = v_f @ 2 \text{ psia} = 0.01623 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1)/\eta_p \\ &= \frac{1}{0.86} (0.01623 \text{ ft}^3/\text{lrbm})(140 - 2) \text{ psia} \\ &\times \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.48 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 94.02 + 0.48 = 94.50 \text{ Btu/lbm}$$

$$h_3 = h_f @ 140 \text{ psia} = 324.92 \text{ Btu/lbm}$$

Mixing chamber:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \xrightarrow{0 \text{ (steady)}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

or,

$$h_4 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(8.5)(94.50) + (1.5)(324.92)}{10} = 129.07 \text{ Btu/lbm}$$

$$v_4 \approx v_f @ h_f = 129.07 \text{ Btu/lbm} = 0.01640 \text{ ft}^3/\text{lrbm}$$

$$\begin{aligned} w_{pII,in} &= v_4(P_5 - P_4)/\eta_p \\ &= (0.01640 \text{ ft}^3/\text{lrbm})(800 - 140) \text{ psia} \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) / (0.86) \\ &= 2.33 \text{ Btu/lbm} \end{aligned}$$

$$h_5 = h_4 + w_{pII,in} = 129.07 + 2.33 = 131.39 \text{ Btu/lbm}$$

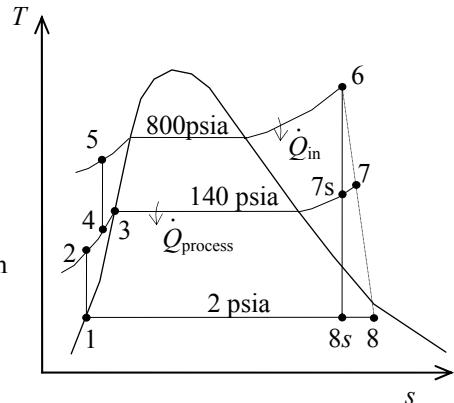

$$\begin{cases} P_6 = 800 \text{ psia} \\ T_6 = 1000^\circ\text{F} \end{cases} \quad \begin{cases} h_6 = 1512.2 \text{ Btu/lbm} \\ s_6 = 1.6812 \text{ Btu/lbm} \cdot \text{R} \end{cases}$$

$$\begin{cases} P_{7s} = 140 \text{ psia} \\ s_{7s} = s_6 \end{cases} \quad h_{7s} = 1287.5 \text{ Btu/lbm}$$

$$\begin{cases} P_{8s} = 2 \text{ psia} \\ s_{8s} = s_6 \end{cases} \quad \begin{cases} x_{8s} = \frac{s_{8s} - s_f}{s_{fg}} = \frac{1.6812 - 0.17499}{1.74444} = 0.8634 \\ h_{8s} = h_f + x_{8s} h_{fg} = 94.02 + (0.8634)(1021.7) = 976.21 \text{ Btu/lbm} \end{cases}$$

Then, $\dot{Q}_{in} = \dot{m}_5(h_6 - h_5) = (10 \text{ lbm/s})(1512.2 - 131.39) \text{ Btu/lbm} = \mathbf{13,810 \text{ Btu/s}}$

$$\begin{aligned} (b) \quad \dot{W}_{T,out} &= \eta_T \dot{W}_{T,s} = \eta_T [\dot{m}_6(h_6 - h_{7s}) + \dot{m}_8(h_{7s} - h_{8s})] \\ &= (0.86)[(10 \text{ lbm/s})(1512.2 - 1287.5) \text{ Btu/lbm} + (1.5 \text{ lbm/s})(1287.5 - 976.21) \text{ Btu/lbm}] \\ &= 4208 \text{ Btu/s} = \mathbf{4440 \text{ kW}} \end{aligned}$$

10-76 A cogeneration plant has two modes of operation. In the first mode, all the steam leaving the turbine at a relatively high pressure is routed to the process heater. In the second mode, 60 percent of the steam is routed to the process heater and remaining is expanded to the condenser pressure. The power produced and the rate at which process heat is supplied in the first mode, and the power produced and the rate of process heat supplied in the second mode are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pl,in}} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(10,000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.15 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 251.42 + 10.15 = 261.57 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg}$$

$$v_3 = v_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pII,in}} &= v_3(P_4 - P_3) \\ &= (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.38 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{\text{pII,in}} = 640.09 + 10.38 = 650.47 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{no steady}} = 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_5 h_5 = \dot{m}_2 h_2 + \dot{m}_4 h_4$$

$$\text{or, } h_5 = \frac{\dot{m}_2 h_2 + \dot{m}_4 h_4}{\dot{m}_5} = \frac{(2)(261.57) + (3)(650.47)}{5} = 494.91 \text{ kJ/kg}$$

$$\begin{cases} P_6 = 10 \text{ MPa} \\ T_6 = 450^\circ\text{C} \end{cases} \begin{cases} h_6 = 3242.4 \text{ kJ/kg} \\ s_6 = 6.4219 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_7 = 0.5 \text{ MPa} \\ s_7 = s_6 \end{cases} \begin{cases} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.4219 - 1.8604}{4.9603} = 0.9196 \\ h_7 = h_f + x_7 h_{fg} = 640.09 + (0.9196)(2108.0) = 2578.6 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_8 = 20 \text{ kPa} \\ s_8 = s_6 \end{cases} \begin{cases} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{6.4219 - 0.8320}{7.0752} = 0.7901 \\ h_8 = h_f + x_8 h_{fg} = 251.42 + (0.7901)(2357.5) = 2114.0 \text{ kJ/kg} \end{cases}$$

When the entire steam is routed to the process heater,

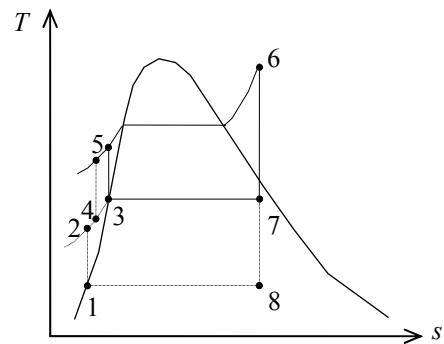

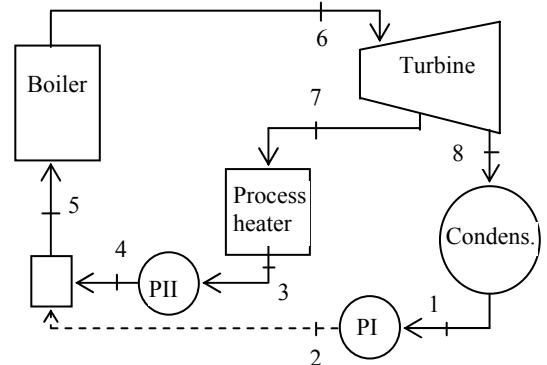

$$\dot{W}_{\text{T,out}} = \dot{m}_6(h_6 - h_7) = (5 \text{ kg/s})(3242.4 - 2578.6) \text{ kJ/kg} = 3319 \text{ kW}$$

$$\dot{Q}_{\text{process}} = \dot{m}_7(h_7 - h_3) = (5 \text{ kg/s})(2578.6 - 640.09) \text{ kJ/kg} = 9693 \text{ kW}$$

(b) When only 60% of the steam is routed to the process heater,

$$\begin{aligned} \dot{W}_{\text{T,out}} &= \dot{m}_6(h_6 - h_7) + \dot{m}_8(h_7 - h_8) \\ &= (5 \text{ kg/s})(3242.4 - 2578.6) \text{ kJ/kg} + (2 \text{ kg/s})(2578.6 - 2114.0) \text{ kJ/kg} = 4248 \text{ kW} \end{aligned}$$

$$\dot{Q}_{\text{process}} = \dot{m}_7(h_7 - h_3) = (3 \text{ kg/s})(2578.6 - 640.09) \text{ kJ/kg} = 5816 \text{ kW}$$

10-77 A cogeneration plant modified with regeneration is to generate power and process heat. The mass flow rate of steam through the boiler for a net power output of 25 MW is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{\text{pl,in}} = \nu_1(P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(1600 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 1.61 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 191.81 + 1.61 = 193.41 \text{ kJ/kg}$$

$$h_3 = h_4 = h_9 = h_f @ 1.6 \text{ MPa} = 858.44 \text{ kJ/kg}$$

$$\nu_4 = \nu_f @ 1.6 \text{ MPa} = 0.001159 \text{ m}^3/\text{kg}$$

$$w_{\text{pII,in}} = \nu_4(P_5 - P_4)$$

$$= (0.001159 \text{ m}^3/\text{kg})(9000 - 400 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 8.57 \text{ kJ/kg}$$

$$h_5 = h_4 + w_{\text{pII,in}} = 858.44 + 8.57 = 867.02 \text{ kJ/kg}$$

$$P_6 = 9 \text{ MPa} \quad h_6 = 3118.8 \text{ kJ/kg}$$

$$T_6 = 400^\circ\text{C} \quad s_6 = 6.2876 \text{ kJ/kg} \cdot \text{K}$$

$$P_7 = 1.6 \text{ MPa} \quad x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.2876 - 2.3435}{4.0765} = 0.9675$$

$$s_7 = s_6 \quad h_7 = h_f + x_7 h_{fg} = 858.44 + (0.9675)(1934.4) = 2730.0 \text{ kJ/kg}$$

$$P_8 = 10 \text{ kPa} \quad x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{6.2876 - 0.6492}{7.4996} = 0.7518$$

$$s_8 = s_6 \quad h_8 = h_f + x_8 h_{fg} = 191.81 + (0.7518)(2392.1) = 1990.2 \text{ kJ/kg}$$

Then, per kg of steam flowing through the boiler, we have

$$w_{T,\text{out}} = (h_6 - h_7) + (1 - y)(h_7 - h_8)$$

$$= (3118.8 - 2730.0) \text{ kJ/kg} + (1 - 0.35)(2730.0 - 1990.2) \text{ kJ/kg}$$

$$= 869.7 \text{ kJ/kg}$$

$$w_{\text{p,in}} = (1 - y)w_{\text{pl,in}} + w_{\text{pII,in}}$$

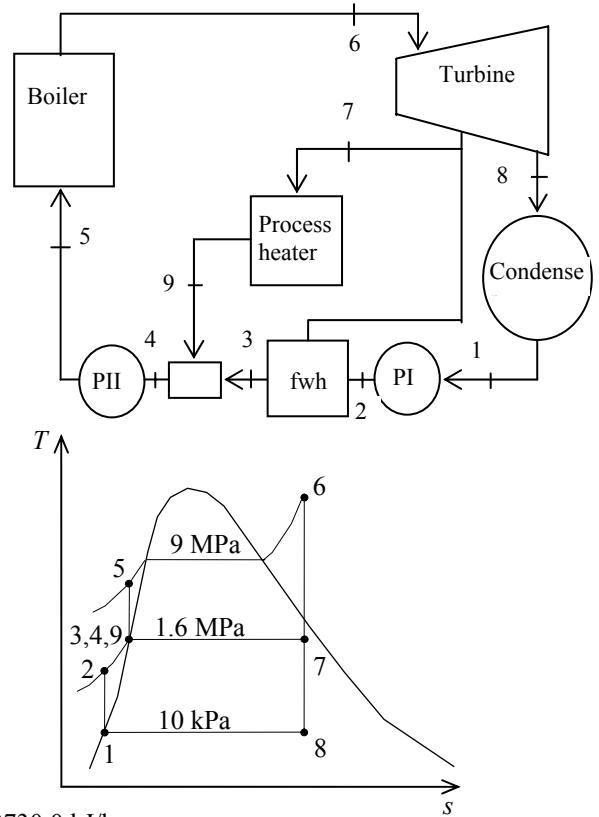

$$= (1 - 0.35)(1.61 \text{ kJ/kg}) + (8.57 \text{ kJ/kg})$$

$$= 9.62 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{\text{p,in}} = 869.7 - 9.62 = 860.1 \text{ kJ/kg}$$

Thus,

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{25,000 \text{ kJ/s}}{860.1 \text{ kJ/kg}} = 29.1 \text{ kg/s}$$

10-78 Problem 10-77 is reconsidered. The effect of the extraction pressure for removing steam from the turbine to be used for the process heater and open feedwater heater on the required mass flow rate is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-79E A cogeneration plant is to generate power while meeting the process steam requirements for a certain industrial application. The net power produced, the rate of process heat supply, and the utilization factor of this plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 \equiv h_f @ 240^{\circ}\text{F} = 208.49 \text{ Btu/lbm}$$

$$h_2 \equiv h_1$$

$$P_3 = 600 \text{ psia} \quad \left\{ \begin{array}{l} h_3 = 1408.0 \text{ Btu/lbm} \\ T_3 = 800^{\circ}\text{F} \quad \left\{ \begin{array}{l} s_3 = s_5 = s_7 = 1.6348 \text{ Btu/lbm \cdot R} \end{array} \right. \end{array} \right.$$

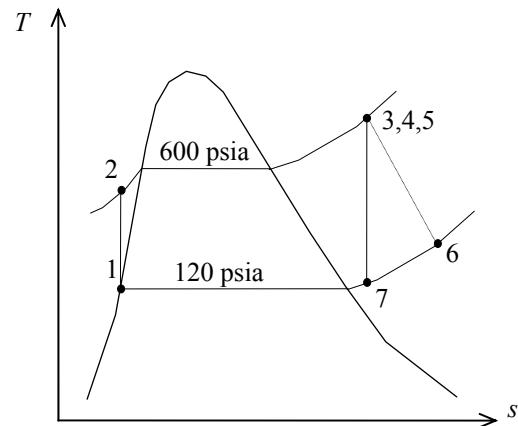

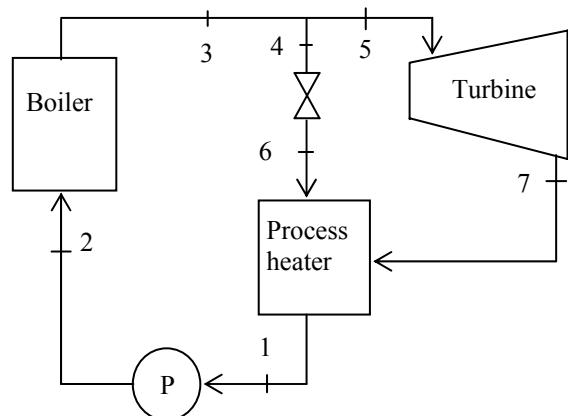

$$h_3 = h_4 = h_5 = h_6$$

$$P_7 = 120 \text{ psia} \quad \left\{ \begin{array}{l} h_7 = 1229.5 \text{ Btu/lbm} \\ s_7 = s_3 \end{array} \right.$$

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m}_5(h_5 - h_7) \\ &= (12 \text{ lbm/s})(1408.0 - 1229.5) \text{ Btu/lbm} \\ &= 2142 \text{ Btu/s} = \mathbf{2260 \text{ kW}} \end{aligned}$$

$$\begin{aligned} (b) \quad \dot{Q}_{\text{process}} &= \sum \dot{m}_i h_i - \sum \dot{m}_e h_e \\ &= \dot{m}_6 h_6 + \dot{m}_7 h_7 - \dot{m}_1 h_1 - \\ &= (6)(1408.0) + (12)(1229.5) - (18)(208.49) \\ &= \mathbf{19,450 \text{ Btu/s}} \end{aligned}$$

(c) $\varepsilon_u = 1$ since all the energy is utilized.

10-80 A Rankine steam cycle modified for a closed feedwater heater and a process heater is considered. The $T-s$ diagram for the ideal cycle is to be sketched; the mass flow rate of the cooling water; and the utilization efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pl,in}} &= v_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(10000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.1 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 191.81 + 10.1 = 201.9 \text{ kJ/kg}$$

$$h_3 = h_8 = h_9 = h_f @ 2000 \text{ kPa} = 908.47 \text{ kJ/kg}$$

$$h_{10} = h_{11} = h_f @ 700 \text{ kPa} = 697.00 \text{ kJ/kg}$$

An energy balance on the closed feedwater heater gives

$$y(h_5 - h_8) = h_3 - h_2$$

$$y = \frac{h_3 - h_2}{h_5 - h_8} = \frac{908.47 - 201.9}{2930 - 908.47} = 0.3495$$

The process heat is expressed as

$$\begin{aligned} \dot{Q}_{\text{process}} &= z\dot{m}(h_6 - h_{10}) = \dot{m}_w c_p \Delta T_w \\ \dot{m}_w &= \frac{z\dot{m}(h_6 - h_{10})}{c_p \Delta T_w} = \frac{0.05(100 \text{ kg/s})(2714 - 697.00) \text{ kJ/kg}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(40^\circ\text{C})} = 60.3 \text{ kg/s} \end{aligned}$$

(c) The net power output is determined from

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{W}_T - \dot{W}_P \\ &= \dot{m}[y(h_4 - h_5) + z(h_4 - h_6) + (1 - y - z)(h_4 - h_7) - w_P] \\ &= (100 \text{ kg/s}) \left[0.3495(3374 - 2930) \text{ kJ/kg} + 0.05(3374 - 2714) \text{ kJ/kg} \right. \\ &\quad \left. + (1 - 0.3495 - 0.05)(3374 - 2089) \text{ kJ/kg} - (10.1 \text{ kJ/kg}) \right] \\ &= 94,970 \text{ kW} \end{aligned}$$

The rate of heat input in the boiler is

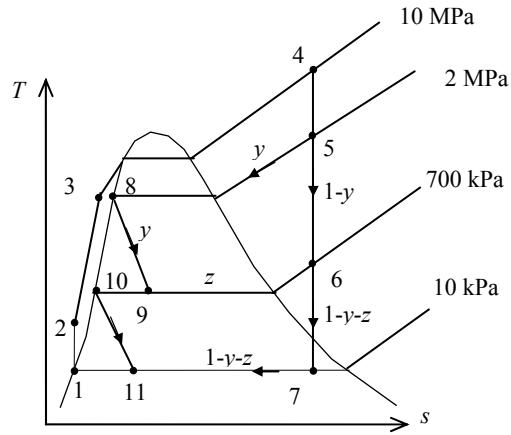

$$\dot{Q}_{\text{in}} = \dot{m}(h_4 - h_3) = (100 \text{ kg/s})(3874 - 908.47) \text{ kJ/kg} = 296,550 \text{ kW}$$

The rate of process heat is

$$\dot{Q}_{\text{process}} = 0.05\dot{m}(h_6 - h_{10}) = 0.05(100 \text{ kg/s})(2714 - 697.00) \text{ kJ/kg} = 10,085 \text{ kW}$$

The utilization efficiency of this cogeneration plant is

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{(94,970 + 10,085) \text{ kW}}{296,550 \text{ kW}} = 0.354 = 35.4\%$$

Combined Gas-Vapor Power Cycles

10-81C The energy source of the steam is the waste energy of the exhausted combustion gases.

10-82C Because the combined gas-steam cycle takes advantage of the desirable characteristics of the gas cycle at high temperature, and those of steam cycle at low temperature, and combines them. The result is a cycle that is more efficient than either cycle executed operated alone.

10-83 A 450-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is an ideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) The analysis of gas cycle yields (Table A-17)

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg}$$

$$P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (14)(1.386) = 19.40 \longrightarrow h_9 = 635.5 \text{ kJ/kg}$$

$$T_{10} = 1400 \text{ K} \longrightarrow h_{10} = 1515.42 \text{ kJ/kg}$$

$$P_{r_{10}} = 450.5$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left(\frac{1}{14}\right)(450.5) = 32.18 \longrightarrow h_{11} = 735.8 \text{ kJ/kg}$$

$$T_{12} = 460 \text{ K} \longrightarrow h_{12} = 462.02 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{\text{pl,in}} = v_1(P_2 - P_1)$$

$$= (0.001017 \text{ m}^3/\text{kg})(600 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.59 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 251.42 + 0.59 = 252.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

$$v_3 = v_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

$$w_{\text{pl,in}} = v_3(P_4 - P_3)$$

$$= (0.001101 \text{ m}^3/\text{kg})(8,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 8.15 \text{ kJ/kg}$$

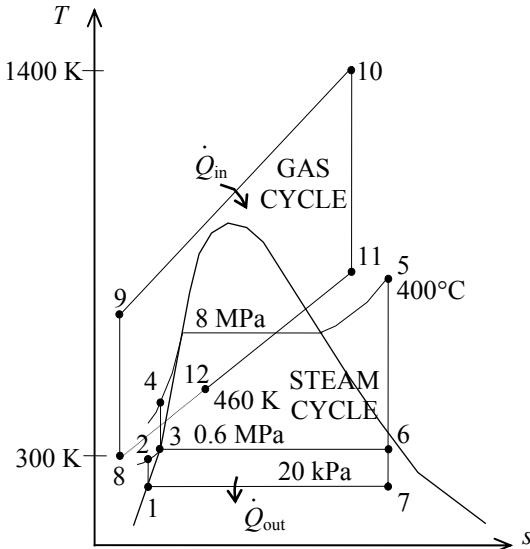

$$h_4 = h_3 + w_{\text{pl,in}} = 670.38 + 8.15 = 678.53 \text{ kJ/kg}$$

$$\begin{cases} P_5 = 8 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{cases} \quad \begin{cases} h_5 = 3139.4 \text{ kJ/kg} \\ s_5 = 6.3658 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_6 = 0.6 \text{ MPa} \\ s_6 = s_5 \end{cases} \quad \begin{cases} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.3658 - 1.9308}{4.8285} = 0.9185 \\ h_6 = h_f + x_6 h_{fg} = 670.38 + (0.9185)(2085.8) = 2586.1 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_7 = 20 \text{ kPa} \\ s_7 = s_5 \end{cases} \quad \begin{cases} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.3658 - 0.8320}{7.0752} = 0.7821 \\ h_7 = h_f + x_7 h_{fg} = 251.42 + (0.7821)(2357.5) = 2095.2 \text{ kJ/kg} \end{cases}$$

Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{d}0(\text{steady})} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s(h_5 - h_4) = \dot{m}_{\text{air}}(h_{11} - h_{12}) \\ \frac{\dot{m}_{\text{air}}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3139.4 - 678.53}{735.80 - 462.02} = \mathbf{8.99 \text{ kg air / kg steam}}\end{aligned}$$

(b) Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{d}0(\text{steady})} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1-y) h_2 = (1) h_3\end{aligned}$$

Thus,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{670.38 - 252.01}{2586.1 - 252.01} = 0.1792 \quad (\text{the fraction of steam extracted})$$

$$\begin{aligned}w_T &= h_5 - h_6 + (1-y)(h_6 - h_7) \\ &= 3139.4 - 2586.1 + (1 - 0.1792)(2586.1 - 2095.2) = 956.23 \text{ kJ/kg}\end{aligned}$$

$$\begin{aligned}w_{\text{net,steam}} &= w_T - w_{p,\text{in}} = w_T - (1-y)w_{p,I} - w_{p,II} \\ &= 956.23 - (1 - 0.1792)(0.59) - 8.15 = 948.56 \text{ kJ/kg}\end{aligned}$$

$$\begin{aligned}w_{\text{net,gas}} &= w_T - w_{C,\text{in}} = (h_{10} - h_{11}) - (h_9 - h_8) \\ &= 1515.42 - 735.8 - (635.5 - 300.19) = 444.3 \text{ kJ/kg}\end{aligned}$$

The net work output per unit mass of gas is

$$w_{\text{net}} = w_{\text{net,gas}} + \frac{1}{8.99} w_{\text{net,steam}} = 444.3 + \frac{1}{8.99}(948.56) = 549.8 \text{ kJ/kg}$$

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{450,000 \text{ kJ/s}}{549.7 \text{ kJ/kg}} = 818.7 \text{ kg/s}$$

and

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{air}}(h_{10} - h_9) = (818.7 \text{ kg/s})(1515.42 - 635.5) \text{ kJ/kg} = \mathbf{720,215 \text{ kW}}$$

$$(c) \quad \eta_{th} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{450,000 \text{ kW}}{720,215 \text{ kW}} = \mathbf{62.5\%}$$

10-84 Problem 10-83 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-85 A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The mass flow rate of air for a specified power output is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (293 \text{ K}) (8)^{0.4/1.4} = 530.8 \text{ K}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\begin{aligned} \longrightarrow T_6 &= T_5 + \frac{T_{6s} - T_5}{\eta_C} \\ &= 293 + \frac{530.8 - 293}{0.85} = 572.8 \text{ K} \end{aligned}$$

$$T_{8s} = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (1373 \text{ K}) \left(\frac{1}{8} \right)^{0.4/1.4} = 758.0 \text{ K}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} = \frac{c_p(T_7 - T_8)}{c_p(T_7 - T_{8s})} \longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 1373 - (0.90)(1373 - 758.0) \\ &= 819.5 \text{ K} \end{aligned}$$

$$T_9 = T_{\text{sat}@6000 \text{ kPa}} = 275.6^\circ\text{C} = 548.6 \text{ K}$$

Fixing the states around the bottom steam cycle yields (Tables A-4, A-5, A-6):

$$h_1 = h_{f@20 \text{ kPa}} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_{f@20 \text{ kPa}} = 0.001017 \text{ m}^3/\text{kg}$$

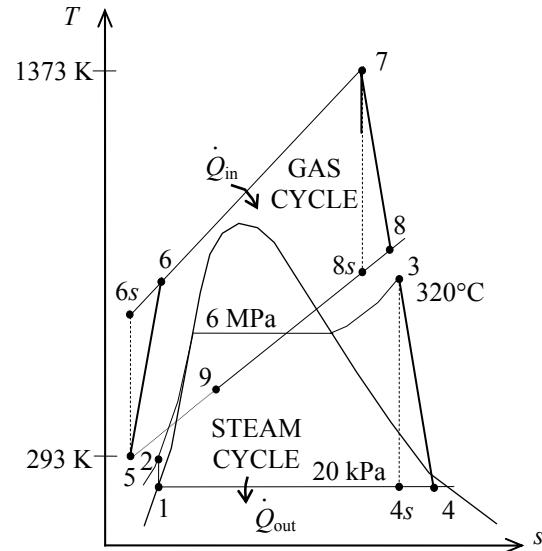

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(6000 - 20) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.08 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 6.08 = 257.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 6000 \text{ kPa} \\ T_3 = 320^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 2953.6 \text{ kJ/kg} \\ s_3 = 6.1871 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 20 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 2035.8 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 2953.6 - (0.90)(2953.6 - 2035.8) \\ &= 2127.6 \text{ kJ/kg} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned} w_{\text{net, gas cycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\ &= c_p(T_7 - T_8) - c_p(T_6 - T_5) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1373 - 819.5 - 572.7 + 293)\text{K} \\ &= 275.2 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\ &= (h_3 - h_4) - w_{P,\text{in}} \\ &= (2953.6 - 2127.6) - 6.08 \\ &= 819.9 \text{ kJ/kg} \end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(1.005)(819.5 - 548.6)}{2953.6 - 257.5} = 0.1010 \dot{m}_a$$

That is, 1 kg of exhaust gases can heat only 0.1010 kg of water. Then, the mass flow rate of air is

$$\dot{m}_a = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{100,000 \text{ kJ/s}}{(1 \times 275.2 + 0.1010 \times 819.9) \text{ kJ/kg air}} = \mathbf{279.3 \text{ kg/s}}$$

10-86 A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The mass flow rate of air for a specified power output is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are

$$c_p = 1.005 \text{ kJ/kg}\cdot\text{K} \text{ and } k = 1.4 \text{ (Table A-2a).}$$

Analysis With an ideal regenerator, the temperature of the air at the compressor exit will be heated to the temperature at the turbine exit. Representing this state by "6a"

$$T_{6a} = T_8 = 819.5 \text{ K}$$

The rate of heat addition in the cycle is

$$\begin{aligned}\dot{Q}_{in} &= \dot{m}_a c_p (T_7 - T_{6a}) \\ &= (279.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{C})(1373 - 819.5) \text{ K} \\ &= 155,370 \text{ kW}\end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{100,000 \text{ kW}}{155,370 \text{ kW}} = \mathbf{0.6436}$$

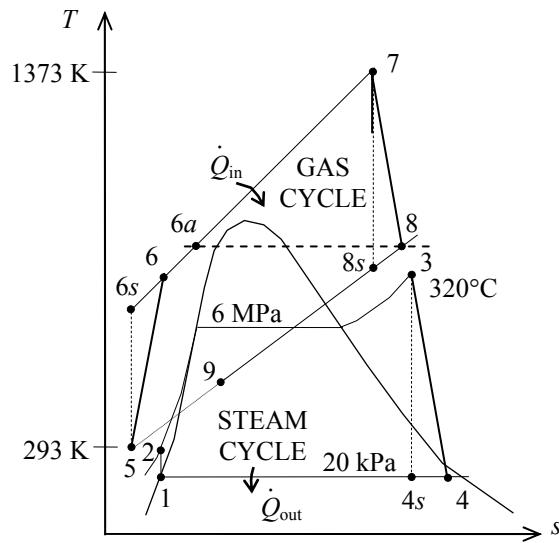

Without the regenerator, the rate of heat addition and the thermal efficiency are

$$\dot{Q}_{in} = \dot{m}_a c_p (T_7 - T_6) = (279.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{C})(1373 - 572.7) \text{ K} = 224,640 \text{ kW}$$

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{100,000 \text{ kW}}{224,640 \text{ kW}} = \mathbf{0.4452}$$

The change in the thermal efficiency due to using the ideal regenerator is

$$\Delta\eta_{th} = 0.6436 - 0.4452 = \mathbf{0.1984}$$

10-87 The component of the combined cycle with the largest exergy destruction of the component of the combined cycle in Prob. 10-86 is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Problem 10-86,

$$T_{\text{source, gas cycle}} = 1373 \text{ K}$$

$$T_{\text{source, steam cycle}} = T_8 = 819.5 \text{ K}$$

$$T_{\text{sink}} = 293 \text{ K}$$

$$s_1 = s_2 = s_f @ 20 \text{ kPa} = 0.8320 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = 6.1871 \text{ kJ/kg} \cdot \text{K}$$

$$s_4 = 6.4627 \text{ kJ/kg} \cdot \text{K}$$

$$q_{\text{in},67} = c_p(T_7 - T_6) = 804.3 \text{ kJ/kg}$$

$$q_{\text{in},23} = h_3 - h_2 = 2696.1 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 1876.2 \text{ kJ/kg}$$

$$\dot{m}_w = 0.1010 \dot{m}_a = 0.1010(279.3) = 28.21 \text{ kg/s}$$

$$\dot{X}_{\text{destroyed},12} = 0 \quad (\text{isentropic process})$$

$$\dot{X}_{\text{destroyed},34} = \dot{m}_w T_0(s_4 - s_3) = (28.21 \text{ kg/s})(293 \text{ K})(6.4627 - 6.1871) = 2278 \text{ kW}$$

$$\begin{aligned}\dot{X}_{\text{destroyed},41} &= \dot{m}_w T_0 \left(s_1 - s_4 + \frac{q_{\text{out}}}{T_{\text{sink}}} \right) \\ &= (28.21 \text{ kg/s})(293 \text{ K}) \left(0.8320 - 6.1871 + \frac{1876.2 \text{ kJ/kg}}{293 \text{ K}} \right) = 8665 \text{ kW}\end{aligned}$$

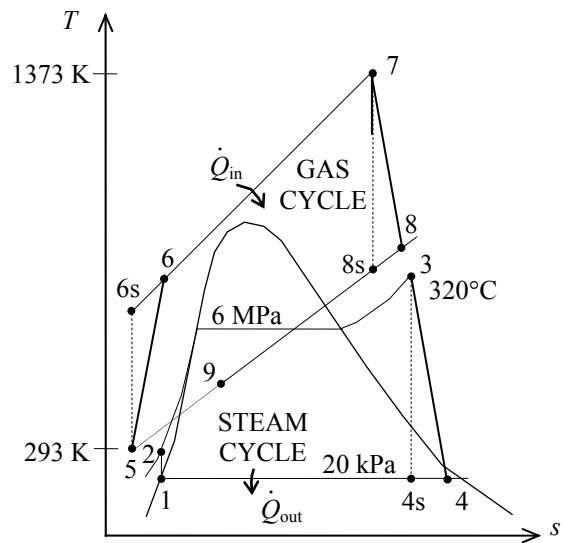

$$\begin{aligned}\dot{X}_{\text{destroyed,heat exchanger}} &= \dot{m}_a T_0 \Delta s_{89} + \dot{m}_w T_0 \Delta s_{23} = \dot{m}_a T_0 \left(c_p \ln \frac{T_9}{T_8} \right) + \dot{m}_a T_0 (s_3 - s_2) \\ &= (279.3)(293) \left[(1.005) \ln \frac{548.6}{819.5} \right] + (28.21)(293)(6.1871 - 0.8320) \\ &= 11260 \text{ kW}\end{aligned}$$

$$\dot{X}_{\text{destroyed},56} = \dot{m}_a T_0 \left(c_p \ln \frac{T_6}{T_5} - R \ln \frac{P_6}{P_5} \right) = (279.3)(293) \left[(1.005) \ln \frac{572.7}{293} - (0.287) \ln(8) \right] = 6280 \text{ kW}$$

$$\dot{X}_{\text{destroyed},67} = \dot{m}_a T_0 \left(c_p \ln \frac{T_7}{T_6} - \frac{q_{\text{in}}}{T_{\text{source}}} \right) = (279.3)(293) \left[(1.005) \ln \frac{1373}{572.7} - \frac{804.3}{1373} \right] = \mathbf{23,970 \text{ kW}}$$

$$\dot{X}_{\text{destroyed},78} = \dot{m}_a T_0 \left(c_p \ln \frac{T_8}{T_7} - R \ln \frac{P_8}{P_7} \right) = (279.3)(293) \left[(1.005) \ln \frac{819.5}{1373} - (0.287) \ln \left(\frac{1}{8} \right) \right] = 6396 \text{ kW}$$

The largest exergy destruction occurs during the heat addition process in the combustor of the gas cycle.

10-88 A 280-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) Using the properties of air from Table A-17, the analysis of gas cycle yields

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg}$$

$$P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (11)(1.386) = 15.25 \longrightarrow h_{9s} = 595.84 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{9s} - h_8}{h_9 - h_8} \longrightarrow h_9 = h_8 + (h_{9s} - h_8)/\eta_C$$

$$= 300.19 + (595.84 - 300.19)/(0.82)$$

$$= 660.74 \text{ kJ/kg}$$

$$T_{10} = 1100 \text{ K} \longrightarrow h_{10} = 1161.07 \text{ kJ/kg}$$

$$P_{r_{10}} = 167.1$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left(\frac{1}{11}\right)(167.1) = 15.19 \longrightarrow h_{11s} = 595.18 \text{ kJ/kg}$$

$$\eta_T = \frac{h_{10} - h_{11}}{h_{10} - h_{11s}} \longrightarrow h_{11} = h_{10} - \eta_T (h_{10} - h_{11s})$$

$$= 1161.07 - (0.86)(1161.07 - 595.18)$$

$$= 674.40 \text{ kJ/kg}$$

$$T_{12} = 420 \text{ K} \longrightarrow h_{12} = 421.26 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pl,in} = v_1(P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(800 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.80 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pl,in} = 191.81 + 0.80 = 192.60 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.8 \text{ MPa} = 720.87 \text{ kJ/kg}$$

$$v_3 = v_f @ 0.8 \text{ MPa} = 0.001115 \text{ m}^3/\text{kg}$$

$$w_{pl,in} = v_3(P_4 - P_3)$$

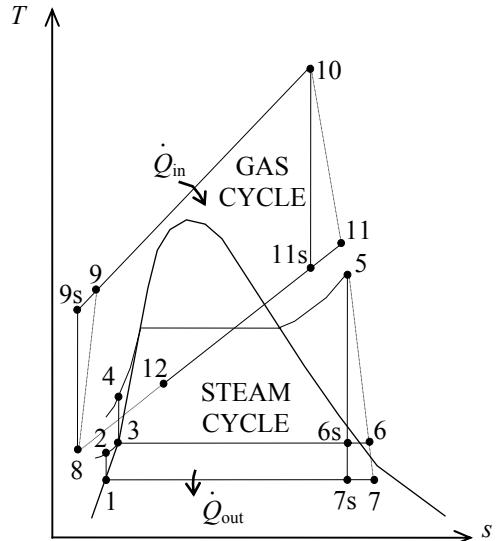

$$= (0.001115 \text{ m}^3/\text{kg})(5000 - 800 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 4.68 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pl,in} = 720.87 + 4.68 = 725.55 \text{ kJ/kg}$$

$$P_5 = 5 \text{ MPa} \quad h_5 = 3069.3 \text{ kJ/kg}$$

$$T_5 = 350^\circ\text{C} \quad s_5 = 6.4516 \text{ kJ/kg} \cdot \text{K}$$

$$P_6 = 0.8 \text{ MPa} \quad \begin{cases} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.4516 - 2.0457}{4.6160} = 0.9545 \\ s_{6s} = s_5 \\ h_{6s} = h_f + x_{6s}h_{fg} = 720.87 + (0.9545)(2085.8) = 2675.1 \text{ kJ/kg} \end{cases}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) = 3069.3 - (0.86)(3069.3 - 2675.1) = 2730.3 \text{ kJ/kg}$$

$$P_7 = 10 \text{ kPa} \quad \begin{cases} x_{7s} = \frac{s_7 - s_f}{s_{fg}} = \frac{6.4516 - 0.6492}{7.4996} = 0.7737 \\ s_7 = s_5 \\ h_{7s} = h_f + x_7 h_{fg} = 191.81 + (0.7737)(2392.1) = 2042.5 \text{ kJ/kg} \end{cases}$$

$$\eta_T = \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T(h_5 - h_{7s}) = 3069.3 - (0.86)(3069.3 - 2042.5) = 2186.3 \text{ kJ/kg}$$

Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s(h_5 - h_4) = \dot{m}_{\text{air}}(h_{11} - h_{12}) \\ \frac{\dot{m}_{\text{air}}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3069.3 - 725.55}{674.40 - 421.26} = \mathbf{9.259 \text{ kg air / kg steam}} \end{aligned}$$

(b) Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow yh_6 + (1-y)h_2 = (1)h_3 \end{aligned}$$

Thus,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{720.87 - 192.60}{2730.3 - 192.60} = 0.2082 \quad (\text{the fraction of steam extracted})$$

$$\begin{aligned} w_T &= \eta_T [h_5 - h_6 + (1-y)(h_6 - h_7)] \\ &= (0.86)[3069.3 - 2730.3 + (1 - 0.2082)(2730.3 - 2186.3)] = 769.8 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} w_{\text{net,steam}} &= w_T - w_{p,\text{in}} = w_T - (1-y)w_{p,I} - w_{p,II} \\ &= 769.8 - (1 - 0.2082)(0.80) - 4.68 = 764.5 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} w_{\text{net,gas}} &= w_T - w_{C,\text{in}} = (h_{10} - h_{11}) - (h_9 - h_8) \\ &= 1161.07 - 674.40 - (660.74 - 300.19) = 126.12 \text{ kJ/kg} \end{aligned}$$

The net work output per unit mass of gas is

$$w_{\text{net}} = w_{\text{net,gas}} + \frac{1}{6.425} w_{\text{net,steam}} = 126.12 + \frac{1}{9.259}(764.5) = 208.69 \text{ kJ/kg}$$

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{280,000 \text{ kJ/s}}{208.69 \text{ kJ/kg}} = 1341.7 \text{ kg/s}$$

and $\dot{Q}_{\text{in}} = \dot{m}_{\text{air}}(h_{10} - h_9) = (1341.7 \text{ kg/s})(1161.07 - 660.74) \text{ kJ/kg} = \mathbf{671,300 \text{ kW}}$

$$(c) \quad \eta_{th} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{280,000 \text{ kW}}{671,300 \text{ kW}} = 0.4171 = \mathbf{41.7\%}$$

10-89 Problem 10-88 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-90 A combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal reheat Rankine cycle. The moisture percentage at the exit of the low-pressure turbine, the steam temperature at the inlet of the high-pressure turbine, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) We obtain the air properties from EES. The analysis of gas cycle is as follows

$$T_7 = 15^\circ\text{C} \longrightarrow h_7 = 288.50 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = 15^\circ\text{C} \\ P_7 = 100 \text{ kPa} \end{array} \right\} s_7 = 5.6648 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 700 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_{8s} = 503.47 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{8s} - h_7}{h_8 - h_7} \longrightarrow h_8 = h_7 + (h_{8s} - h_7)/\eta_C$$

$$= 290.16 + (503.47 - 290.16)/(0.80)$$

$$= 557.21 \text{ kJ/kg}$$

$$T_9 = 950^\circ\text{C} \longrightarrow h_9 = 1304.8 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_9 = 950^\circ\text{C} \\ P_9 = 700 \text{ kPa} \end{array} \right\} s_9 = 6.6456 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{10} = 100 \text{ kPa} \\ s_{10} = s_9 \end{array} \right\} h_{10s} = 763.79 \text{ kJ/kg}$$

$$\eta_T = \frac{h_9 - h_{10}}{h_9 - h_{10s}} \longrightarrow h_{10} = h_9 - \eta_T(h_9 - h_{10s})$$

$$= 1304.8 - (0.80)(1304.8 - 763.79)$$

$$= 871.98 \text{ kJ/kg}$$

$$T_{11} = 200^\circ\text{C} \longrightarrow h_{11} = 475.62 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6 or from EES),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pl,in} = v_1(P_2 - P_1)/\eta_p$$

$$= (0.00101 \text{ m}^3/\text{kg})(6000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.80$$

$$= 7.56 \text{ kJ/kg}$$

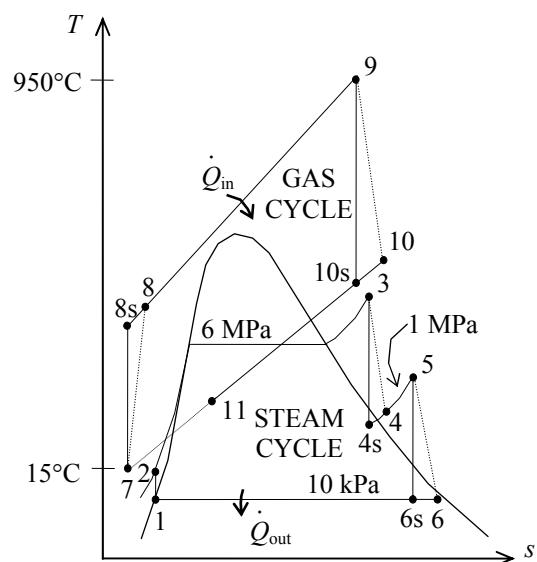

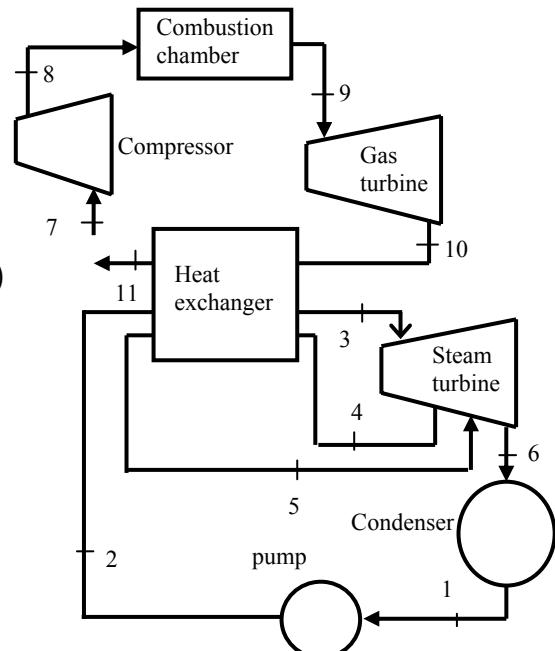

$$h_2 = h_1 + w_{pl,in} = 191.81 + 7.56 = 199.37 \text{ kJ/kg}$$

$$P_5 = 1 \text{ MPa} \quad h_5 = 3264.5 \text{ kJ/kg}$$

$$T_5 = 400^\circ\text{C} \quad s_5 = 7.4670 \text{ kJ/kg} \cdot \text{K}$$

$$P_6 = 10 \text{ kPa} \quad \left\{ \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.4670 - 0.6492}{7.4996} = 0.9091 \\ s_{6s} = s_5 \end{array} \right.$$

$$h_{6s} = h_f + x_{6s}h_{fg} = 191.81 + (0.9091)(2392.1) = 2366.4 \text{ kJ/kg}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) \\ = 3264.5 - (0.80)(3264.5 - 2366.4) \\ = 2546.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ h_6 = 2546.5 \text{ kJ/kg} \end{array} \right\} x_6 = 0.9842$$

$$\text{Moisture Percentage} = 1 - x_6 = 1 - 0.9842 = 0.0158 = \mathbf{1.6\%}$$

(b) Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_s (h_3 - h_2) + \dot{m}_s (h_5 - h_4) &= \dot{m}_{\text{air}} (h_{10} - h_{11}) \\ (1.15)[(3346.5 - 199.37) + (3264.5 - h_4)] &= (10)(871.98 - 475.62) \longrightarrow h_4 = 2965.0 \text{ kJ/kg} \end{aligned}$$

Also,

$$\left. \begin{array}{l} P_3 = 6 \text{ MPa} \\ T_3 = ? \end{array} \right\} h_3 = \quad \left. \begin{array}{l} P_4 = 1 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} h_{4s} =$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s})$$

The temperature at the inlet of the high-pressure turbine may be obtained by a trial-error approach or using EES from the above relations. The answer is $T_3 = \mathbf{468.0^\circ C}$. Then, the enthalpy at state 3 becomes: $h_3 = 3346.5 \text{ kJ/kg}$

$$(c) \quad \dot{W}_{T,\text{gas}} = \dot{m}_{\text{air}} (h_9 - h_{10}) = (10 \text{ kg/s})(1304.8 - 871.98) \text{ kJ/kg} = 4328 \text{ kW}$$

$$\dot{W}_{C,\text{gas}} = \dot{m}_{\text{air}} (h_8 - h_7) = (10 \text{ kg/s})(557.21 - 288.50) \text{ kJ/kg} = 2687 \text{ kW}$$

$$\dot{W}_{\text{net,gas}} = \dot{W}_{T,\text{gas}} - \dot{W}_{C,\text{gas}} = 4328 - 2687 = 1641 \text{ kW}$$

$$\dot{W}_{T,\text{steam}} = \dot{m}_s (h_3 - h_4 + h_5 - h_6) = (1.15 \text{ kg/s})(3346.5 - 2965.0 + 3264.5 - 2546.0) \text{ kJ/kg} = 1265 \text{ kW}$$

$$\dot{W}_{P,\text{steam}} = \dot{m}_s w_{pump} = (1.15 \text{ kg/s})(7.564) \text{ kJ/kg} = 8.7 \text{ kW}$$

$$\dot{W}_{\text{net,steam}} = \dot{W}_{T,\text{steam}} - \dot{W}_{P,\text{steam}} = 1265 - 8.7 = 1256 \text{ kW}$$

$$\dot{W}_{\text{net,plant}} = \dot{W}_{\text{net,gas}} + \dot{W}_{\text{net,steam}} = 1641 + 1256 = \mathbf{2897 \text{ kW}}$$

$$(d) \quad \dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_9 - h_8) = (10 \text{ kg/s})(1304.8 - 557.21) \text{ kJ/kg} = 7476 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net,plant}}}{\dot{Q}_{\text{in}}} = \frac{2897 \text{ kW}}{7476 \text{ kW}} = 0.388 = \mathbf{38.8\%}$$

Special Topic: Binary Vapor Cycles

10-91C In binary vapor power cycles, both cycles are vapor cycles. In the combined gas-steam power cycle, one of the cycles is a gas cycle.

10-92C Binary power cycle is a cycle which is actually a combination of two cycles; one in the high temperature region, and the other in the low temperature region. Its purpose is to increase thermal efficiency.

10-93C Steam is not an ideal fluid for vapor power cycles because its critical temperature is low, its saturation dome resembles an inverted V, and its condenser pressure is too low.

10-94C Because mercury has a high critical temperature, relatively low critical pressure, but a very low condenser pressure. It is also toxic, expensive, and has a low enthalpy of vaporization.

10-95 Consider the heat exchanger of a binary power cycle. The working fluid of the topping cycle (cycle A) enters the heat exchanger at state 1 and leaves at state 2. The working fluid of the bottoming cycle (cycle B) enters at state 3 and leaves at state 4. Neglecting any changes in kinetic and potential energies, and assuming the heat exchanger is well-insulated, the steady-flow energy balance relation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\phi_0(\text{steady})} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ \dot{m}_A h_2 + \dot{m}_B h_4 &= \dot{m}_A h_1 + \dot{m}_B h_3 \text{ or } \dot{m}_A(h_2 - h_1) = \dot{m}_B(h_3 - h_4)\end{aligned}$$

Thus,

$$\frac{\dot{m}_A}{\dot{m}_B} = \frac{h_3 - h_4}{h_2 - h_1}$$

Review Problems

10-96 A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The thermal efficiency of the cycle is to be compared when it is operated so that the liquid enters the pump as a saturated liquid against that when the liquid enters as a subcooled liquid.

determined power produced by the turbine and consumed by the pump are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@50\text{ kPa}} = 340.54 \text{ kJ/kg}$$

$$v_1 = v_{f@20\text{ kPa}} = 0.001030 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(6000 - 50)\text{kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.13 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 340.54 + 6.13 = 346.67 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 6000 \text{ kPa} \\ T_3 = 600^\circ\text{C} \end{cases} \quad \begin{cases} h_3 = 3658.8 \text{ kJ/kg} \\ s_3 = 7.1693 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 50 \text{ kPa} \\ s_4 = s_3 \end{cases} \quad \begin{cases} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{7.1693 - 1.0912}{6.5019} = 0.9348 \\ h_4 = h_f + x_4 h_{fg} = 340.54 + (0.9348)(2304.7) = 2495.0 \text{ kJ/kg} \end{cases}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 3658.8 - 346.67 = 3312.1 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2495.0 - 340.54 = 2154.5 \text{ kJ/kg}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2154.5}{3312.1} = \mathbf{0.3495}$$

When the liquid enters the pump 11.3°C cooler than a saturated liquid at the condenser pressure, the enthalpies become

$$\begin{cases} P_1 = 50 \text{ kPa} \\ T_1 = T_{\text{sat}@50\text{ kPa}} - 11.3 = 81.3 - 11.3 = 70^\circ\text{C} \end{cases} \quad \begin{cases} h_1 \cong h_{f@70^\circ\text{C}} = 293.07 \text{ kJ/kg} \\ v_1 \cong v_{f@70^\circ\text{C}} = 0.001023 \text{ m}^3/\text{kg} \end{cases}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001023 \text{ m}^3/\text{kg})(6000 - 50)\text{kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.09 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 293.07 + 6.09 = 299.16 \text{ kJ/kg}$$

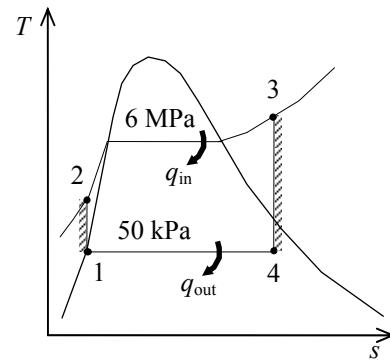

Then,

$$q_{\text{in}} = h_3 - h_2 = 3658.8 - 299.16 = 3359.6 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2495.0 - 293.09 = 2201.9 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2201.9}{3359.6} = \mathbf{0.3446}$$

The thermal efficiency slightly decreases as a result of subcooling at the pump inlet.

10-97E A geothermal power plant operating on the simple Rankine cycle using an organic fluid as the working fluid is considered. The exit temperature of the geothermal water from the vaporizer, the rate of heat rejection from the working fluid in the condenser, the mass flow rate of geothermal water at the preheater, and the thermal efficiency of the Level I cycle of this plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The exit temperature of geothermal water from the vaporizer is determined from the steady-flow energy balance on the geothermal water (brine),

$$\begin{aligned}\dot{Q}_{\text{brine}} &= \dot{m}_{\text{brine}} c_p (T_2 - T_1) \\ -22,790,000 \text{ Btu/h} &= (384,286 \text{ lbm/h})(1.03 \text{ Btu/lbm} \cdot ^\circ\text{F})(T_2 - 325^\circ\text{F}) \\ T_2 &= \mathbf{267.4^\circ\text{F}}\end{aligned}$$

(b) The rate of heat rejection from the working fluid to the air in the condenser is determined from the steady-flow energy balance on air,

$$\begin{aligned}\dot{Q}_{\text{air}} &= \dot{m}_{\text{air}} c_p (T_9 - T_8) \\ &= (4,195,100 \text{ lbm/h})(0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(84.5 - 55^\circ\text{F}) \\ &= \mathbf{29.7 \text{ MBtu/h}}\end{aligned}$$

(c) The mass flow rate of geothermal water at the preheater is determined from the steady-flow energy balance on the geothermal water,

$$\begin{aligned}\dot{Q}_{\text{geo}} &= \dot{m}_{\text{geo}} c_p (T_{\text{out}} - T_{\text{in}}) \\ -11,140,000 \text{ Btu/h} &= \dot{m}_{\text{geo}} (1.03 \text{ Btu/lbm} \cdot ^\circ\text{F})(154.0 - 211.8^\circ\text{F}) \\ \dot{m}_{\text{geo}} &= \mathbf{187,120 \text{ lbm/h}}\end{aligned}$$

(d) The rate of heat input is

$$\begin{aligned}\dot{Q}_{\text{in}} &= \dot{Q}_{\text{vaporizer}} + \dot{Q}_{\text{reheater}} = 22,790,000 + 11,140,000 \\ &= 33,930,000 \text{ Btu/h}\end{aligned}$$

and

$$\dot{W}_{\text{net}} = 1271 - 200 = 1071 \text{ kW}$$

Then,

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1071 \text{ kW}}{33,930,000 \text{ Btu/h}} \left(\frac{3412.14 \text{ Btu}}{1 \text{ kWh}} \right) = \mathbf{10.8\%}$$

10-98 A steam power plant operating on an ideal Rankine cycle with two stages of reheat is considered. The thermal efficiency of the cycle and the mass flow rate of the steam are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 30 \text{ kPa} = 289.18 \text{ kJ/kg}$$

$$v_1 = v_f @ 30 \text{ kPa} = 0.001022 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,in} &= v_1(P_2 - P_1) \\ &= (0.001022 \text{ m}^3/\text{kg})(10,000 - 30 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.19 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,in} = 289.18 + 10.19 = 299.37 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 10 \text{ MPa} \\ T_3 = 550^\circ\text{C} \end{cases} \quad \begin{cases} h_3 = 3500.9 \text{ kJ/kg} \\ s_3 = 6.7561 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_4 = 4 \text{ MPa} \\ s_4 = s_3 \end{cases} \quad \begin{cases} h_4 = 3204.9 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_5 = 4 \text{ MPa} \\ T_5 = 550^\circ\text{C} \end{cases} \quad \begin{cases} h_5 = 3559.7 \text{ kJ/kg} \\ s_5 = 7.2335 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_6 = 2 \text{ MPa} \\ s_6 = s_5 \end{cases} \quad \begin{cases} h_6 = 3321.1 \text{ kJ/kg} \end{cases}$$

$$\begin{cases} P_7 = 2 \text{ MPa} \\ T_7 = 550^\circ\text{C} \end{cases} \quad \begin{cases} h_7 = 3578.4 \text{ kJ/kg} \\ s_7 = 7.5706 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_8 = 30 \text{ kPa} \\ s_8 = s_7 \end{cases} \quad \begin{cases} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{7.5706 - 0.9441}{6.8234} = 0.9711 \\ h_8 = h_f + x_8 h_{fg} = 289.18 + (0.9711)(2335.3) = 2557.1 \text{ kJ/kg} \end{cases}$$

Then,

$$\begin{aligned} q_{in} &= (h_3 - h_2) + (h_5 - h_4) + (h_7 - h_6) \\ &= 3500.9 - 299.37 + 3559.7 - 3204.9 + 3578.4 - 3321.1 = 3813.7 \text{ kJ/kg} \end{aligned}$$

$$q_{out} = h_8 - h_1 = 2557.1 - 289.18 = 2267.9 \text{ kJ/kg}$$

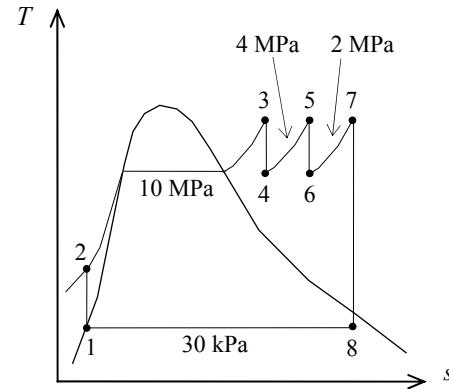

$$w_{net} = q_{in} - q_{out} = 3813.7 - 2267.9 = 1545.8 \text{ kJ/kg}$$

Thus,

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{1545.8 \text{ kJ/kg}}{3813.7 \text{ kJ/kg}} = 0.4053 = \mathbf{40.5\%}$$

(b) The mass flow rate of the steam is then

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{75,000 \text{ kJ/s}}{1545.8 \text{ kJ/kg}} = \mathbf{48.5 \text{ kg/s}}$$

10-99 A steam power plant operating on the ideal Rankine cycle with reheating is considered. The reheat pressures of the cycle are to be determined for the cases of single and double reheat.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Single Reheat: From the steam tables (Tables A-4, A-5, and A-6),

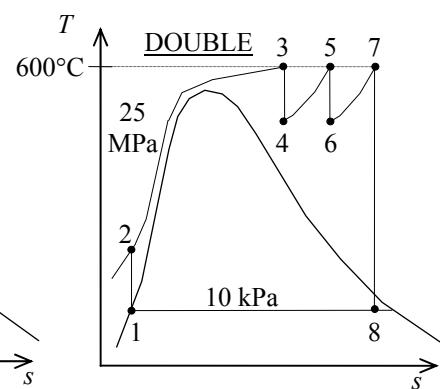

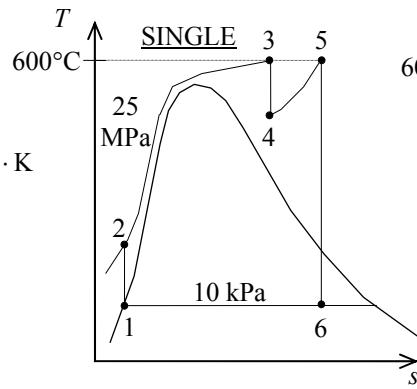

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ x_6 = 0.92 \end{array} \right\} \begin{array}{l} h_6 = h_f + x_6 h_{fg} = 191.81 + (0.92)(2392.1) = 2392.5 \text{ kJ/kg} \\ s_6 = s_f + x_6 s_{fg} = 0.6492 + (0.92)(7.4996) = 7.5488 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} T_5 = 600^\circ\text{C} \\ s_5 = s_6 \end{array} \right\} P_5 = 2780 \text{ kPa}$$

(b) Double Reheat:

$$\left. \begin{array}{l} P_3 = 25 \text{ MPa} \\ T_3 = 600^\circ\text{C} \end{array} \right\} s_3 = 6.3637 \text{ kJ/kg} \cdot \text{K}$$

$$\begin{array}{ll} P_4 = P_x & \text{and} \\ s_4 = s_3 & T_5 = 600^\circ\text{C} \end{array}$$

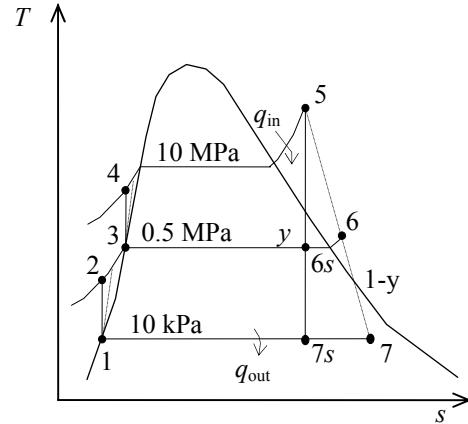

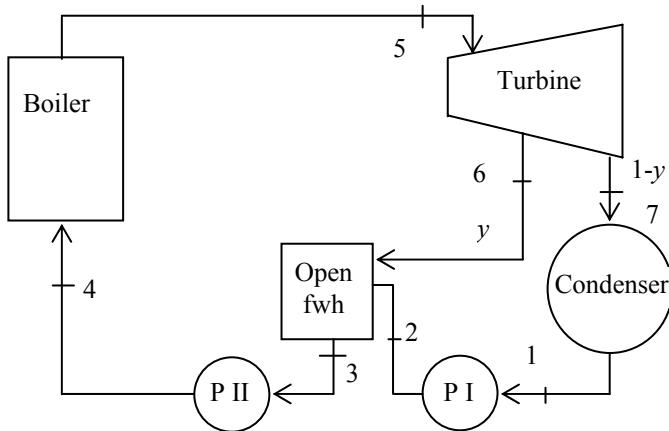

Any pressure P_x selected between the limits of 25 MPa and 2.78 MPa will satisfy the requirements, and can be used for the double reheat pressure.

10-100 An 150-MW steam power plant operating on a regenerative Rankine cycle with an open feedwater heater is considered. The mass flow rate of steam through the boiler, the thermal efficiency of the cycle, and the irreversibility associated with the regeneration process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pI,in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(500 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) \\ &= 0.52 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{pI,in}} = 191.81 + 0.52 = 192.33 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 0.5 \text{ MPa} \\ \text{satliquid} \end{cases} \quad \begin{cases} h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg} \\ \nu_3 = \nu_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg} \end{cases}$$

$$\begin{aligned} w_{\text{pII,in}} &= \nu_3 (P_4 - P_3) / \eta_p \\ &= (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) \\ &= 10.93 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{\text{pII,in}} = 640.09 + 10.93 = 651.02 \text{ kJ/kg}$$

$$\begin{cases} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.5995 - 1.8604}{4.9603} = 0.9554$$

$$\begin{cases} P_{6s} = 0.5 \text{ MPa} \\ s_{6s} = s_5 \end{cases} \quad \begin{cases} h_{6s} = h_f + x_{6s} h_{fg} = 640.09 + (0.9554)(2108.0) \\ = 2654.1 \text{ kJ/kg} \end{cases}$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) \\ &= 3375.1 - (0.80)(3375.1 - 2654.1) \\ &= 2798.3 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} x_{7s} &= \frac{s_{7s} - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = 0.7934 \\ P_{7s} = 10 \text{ kPa} \quad \left. \begin{aligned} h_{7s} &= h_f + x_{7s} h_{fg} = 191.81 + (0.7934)(2392.1) \\ s_{7s} &= s_5 = 2089.7 \text{ kJ/kg} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T(h_5 - h_{7s}) \\ &= 3375.1 - (0.80)(3375.1 - 2089.7) \\ &= 2346.8 \text{ kJ/kg} \end{aligned}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system}^{\text{0(steady)}} = 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow yh_6 + (1-y)h_2 = 1(h_3) \end{aligned}$$

where y is the fraction of steam extracted ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{640.09 - 192.33}{2798.3 - 192.33} = 0.1718$$

Then, $q_{in} = h_5 - h_4 = 3375.1 - 651.02 = 2724.1 \text{ kJ/kg}$

$$q_{out} = (1 - y)(h_7 - h_1) = (1 - 0.1718)(2346.8 - 191.81) = 1784.7 \text{ kJ/kg}$$

$$w_{net} = q_{in} - q_{out} = 2724.1 - 1784.7 = 939.4 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{150,000 \text{ kJ/s}}{939.4 \text{ kJ/kg}} = \mathbf{159.7 \text{ kg/s}}$$

(b) The thermal efficiency is determined from

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{1784.7 \text{ kJ/kg}}{2724.1 \text{ kJ/kg}} = \mathbf{34.5\%}$$

Also,

$$\begin{aligned} P_6 &= 0.5 \text{ MPa} \\ h_6 &= 2798.3 \text{ kJ/kg} \end{aligned} \left. \begin{aligned} s_6 &= 6.9453 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\}$$

$$s_3 = s_f @ 0.5 \text{ MPa} = 1.8604 \text{ kJ/kg} \cdot \text{K}$$

$$s_2 = s_1 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

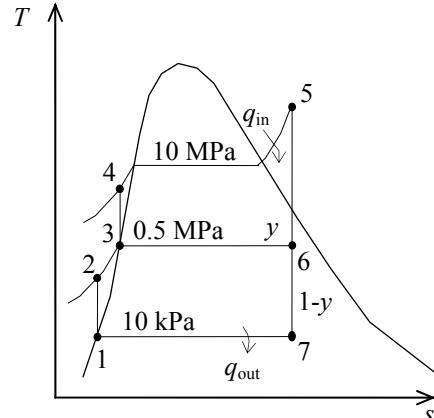

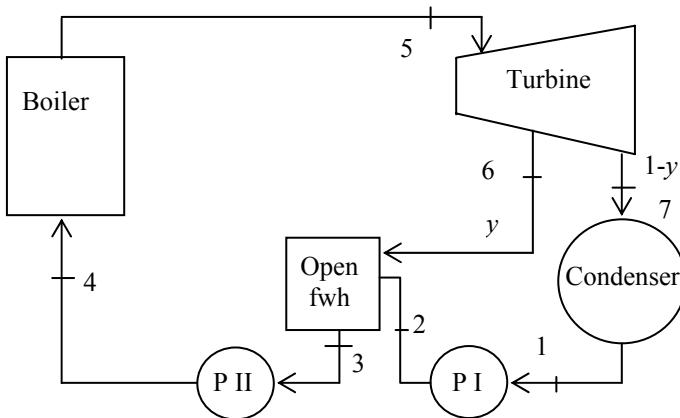

Then the irreversibility (or exergy destruction) associated with this regeneration process is

$$\begin{aligned} i_{regen} &= T_0 s_{gen} = T_0 \left(\sum m_e s_e - \sum m_t s_i + \frac{q_{surr}}{T_L} \right)^{\text{0}} = T_0 [s_3 - ys_6 - (1-y)s_2] \\ &= (303 \text{ K})[1.8604 - (0.1718)(6.9453) - (1 - 0.1718)(0.6492)] \\ &= \mathbf{39.25 \text{ kJ/kg}} \end{aligned}$$

10-101 An 150-MW steam power plant operating on an ideal regenerative Rankine cycle with an open feedwater heater is considered. The mass flow rate of steam through the boiler, the thermal efficiency of the cycle, and the irreversibility associated with the regeneration process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{\text{pl,in}} = \nu_1(P_2 - P_1) \\ = (0.00101 \text{ m}^3/\text{kg})(500 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.50 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 191.81 + 0.50 = 192.30 \text{ kJ/kg}$$

$$P_3 = 0.5 \text{ MPa} \quad \left. \begin{array}{l} h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg} \\ \text{sat.liquid} \end{array} \right\} \nu_3 = \nu_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg}$$

$$w_{\text{pII,in}} = \nu_3(P_4 - P_3) \\ = (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 10.38 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{\text{pII,in}} = 640.09 + 10.38 = 650.47 \text{ kJ/kg}$$

$$P_5 = 10 \text{ MPa} \quad \left. \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ T_5 = 500^\circ\text{C} \end{array} \right\} s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K}$$

$$P_6 = 0.5 \text{ MPa} \quad \left. \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.5995 - 1.8604}{4.9603} = 0.9554 \\ s_6 = s_5 \end{array} \right\} h_6 = h_f + x_6 h_{fg} = 640.09 + (0.9554)(2108.0) = 2654.1 \text{ kJ/kg}$$

$$P_7 = 10 \text{ kPa} \quad \left. \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = 0.7934 \\ s_7 = s_5 \end{array} \right\} h_7 = h_f + x_7 h_{fg} = 191.81 + (0.7934)(2392.1) = 2089.7 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy equation applied to the feedwater heaters. Noting that $\dot{Q} \approx \dot{W} \approx \Delta ke \approx \Delta pe \approx 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{(0(steady))}} = 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1-y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{640.09 - 192.31}{2654.1 - 192.31} = 0.1819$$

Then, $q_{\text{in}} = h_5 - h_4 = 3375.1 - 650.47 = 2724.6 \text{ kJ/kg}$

$$q_{\text{out}} = (1 - y)(h_7 - h_1) = (1 - 0.1819)(2089.7 - 191.81) = 1552.7 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2724.6 - 1552.7 = 1172.0 \text{ kJ/kg}$$

and $\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150,000 \text{ kJ/s}}{1171.9 \text{ kJ/kg}} = \mathbf{128.0 \text{ kg/s}}$

(b) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1552.7 \text{ kJ/kg}}{2724.7 \text{ kJ/kg}} = \mathbf{43.0\%}$$

Also,

$$s_6 = s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_f @ 0.5 \text{ MPa} = 1.8604 \text{ kJ/kg} \cdot \text{K}$$

$$s_2 = s_1 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

Then the irreversibility (or exergy destruction) associated with this regeneration process is

$$\begin{aligned} i_{\text{regen}} &= T_0 s_{\text{gen}} = T_0 \left(\sum m_e s_e - \sum m_i s_i + \frac{q_{\text{surr}}}{T_L} \right) = T_0 [s_3 - y s_6 - (1 - y) s_2] \\ &= (303 \text{ K}) [1.8604 - (0.1819)(6.5995) - (1 - 0.1819)(0.6492)] \\ &= \mathbf{39.0 \text{ kJ/kg}} \end{aligned}$$

10-102 An ideal reheat-regenerative Rankine cycle with one open feedwater heater is considered. The fraction of steam extracted for regeneration and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 15 \text{ kPa} = 0.001014 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pl,in}} &= \nu_1(P_2 - P_1) \\ &= (0.001014 \text{ m}^3/\text{kg})(600 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.59 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 225.94 + 0.59 = 226.53 \text{ kJ/kg}$$

$$\begin{aligned} P_3 &= 0.6 \text{ MPa} \quad \left. \begin{aligned} h_3 &= h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \text{sat. liquid} \quad \nu_3 &= \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg} \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} w_{\text{pII,in}} &= \nu_3(P_4 - P_3) \\ &= (0.001101 \text{ m}^3/\text{kg})(10,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.35 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{\text{pII,in}} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$\begin{aligned} P_5 &= 10 \text{ MPa} \quad \left. \begin{aligned} h_5 &= 3375.1 \text{ kJ/kg} \\ T_5 &= 500^\circ\text{C} \quad \left. \begin{aligned} s_5 &= 6.5995 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_6 &= 1.0 \text{ MPa} \quad \left. \begin{aligned} h_6 &= 2783.8 \text{ kJ/kg} \\ s_6 &= s_5 \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_7 &= 1.0 \text{ MPa} \quad \left. \begin{aligned} h_7 &= 3479.1 \text{ kJ/kg} \\ T_7 &= 500^\circ\text{C} \quad \left. \begin{aligned} s_7 &= 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_8 &= 0.6 \text{ MPa} \quad \left. \begin{aligned} h_8 &= 3310.2 \text{ kJ/kg} \\ s_8 &= s_7 \end{aligned} \right\} \end{aligned}$$

$$\begin{aligned} P_9 &= 15 \text{ kPa} \quad \left. \begin{aligned} x_9 &= \frac{s_9 - s_f}{s_{fg}} = \frac{7.7642 - 0.7549}{7.2522} = 0.9665 \\ s_9 &= s_7 \end{aligned} \right\} \\ h_9 &= h_f + x_9 h_{fg} = 225.94 + (0.9665)(2372.3) = 2518.8 \text{ kJ/kg} \end{aligned}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{sh0(steady)}} = 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_8 + (1-y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted ($= \dot{m}_8 / \dot{m}_3$). Solving for y ,

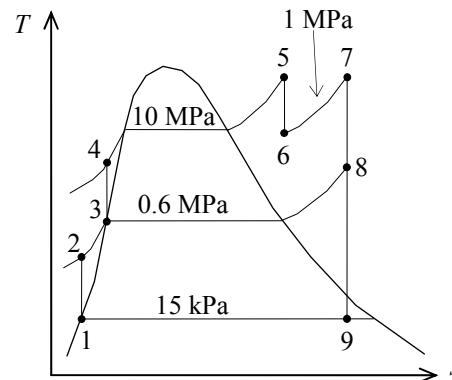

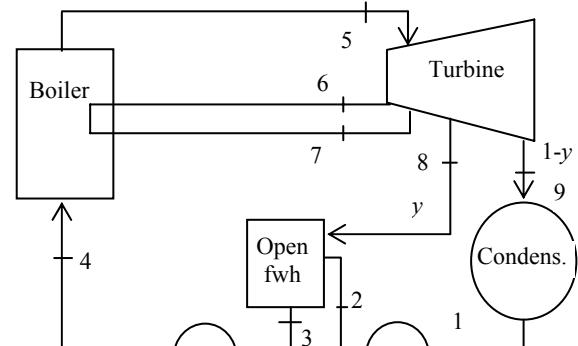

$$y = \frac{h_3 - h_2}{h_8 - h_2} = \frac{670.38 - 226.53}{3310.2 - 226.53} = \mathbf{0.144}$$

(b) The thermal efficiency is determined from

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) = (3375.1 - 680.73) + (3479.1 - 2783.8) = 3389.7 \text{ kJ/kg}$$

$$q_{\text{out}} = (1-y)(h_9 - h_1) = (1 - 0.144)(2518.8 - 225.94) = 1962.7 \text{ kJ/kg}$$

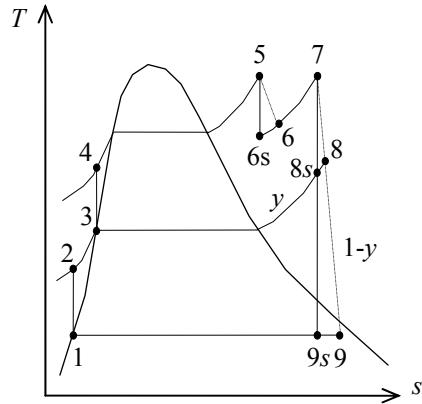

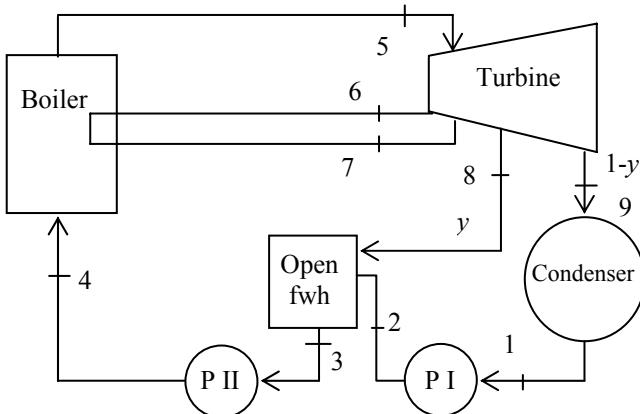

$$\text{and } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1962.7 \text{ kJ/kg}}{3389.7 \text{ kJ/kg}} = \mathbf{42.1\%}$$

10-103 A nonideal reheat-regenerative Rankine cycle with one open feedwater heater is considered. The fraction of steam extracted for regeneration and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 15 \text{ kPa} = 0.001014 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.001014 \text{ m}^3/\text{kg})(600 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.59 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,\text{in}} = 225.94 + 0.59 = 226.54 \text{ kJ/kg}$$

$$\begin{cases} P_3 = 0.6 \text{ MPa} \\ \text{sat. liquid} \end{cases} \quad \begin{cases} h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \nu_3 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg} \end{cases}$$

$$\begin{aligned} w_{pII,\text{in}} &= \nu_3(P_4 - P_3) \\ &= (0.001101 \text{ m}^3/\text{kg})(10,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.35 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII,\text{in}} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$\begin{cases} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_{6s} = 1.0 \text{ MPa} \\ s_{6s} = s_5 \end{cases} \quad \begin{cases} h_{6s} = 2783.8 \text{ kJ/kg} \end{cases}$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) \\ &= 3375.1 - (0.84)(3375.1 - 2783.8) \\ &= 2878.4 \text{ kJ/kg} \end{aligned}$$

$$\begin{cases} P_7 = 1.0 \text{ MPa} \\ T_7 = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_7 = 3479.1 \text{ kJ/kg} \\ s_7 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_{8s} = 0.6 \text{ MPa} \\ s_{8s} = s_7 \end{cases} \quad \begin{cases} h_{8s} = 3310.2 \text{ kJ/kg} \end{cases}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} \longrightarrow h_8 = h_7 - \eta_T(h_7 - h_{8s}) = 3479.1 - (0.84)(3479.1 - 3310.2) \\ &= 3337.2 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{array}{l} P_{9_s} = 15 \text{ kPa} \\ s_{9_s} = s_7 \end{array} \right\} x_{9_s} = \frac{s_{9_s} - s_f}{s_{fg}} = \frac{7.7642 - 0.7549}{7.2522} = 0.9665$$

$$h_{9_s} = h_f + x_{9_s}h_{fg} = 225.94 + (0.9665)(2372.3) = 2518.8 \text{ kJ/kg}$$

$$\eta_T = \frac{h_7 - h_9}{h_7 - h_{9_s}} \longrightarrow h_9 = h_7 - \eta_T(h_7 - h_{9_s}) = 3479.1 - (0.84)(3479.1 - 2518.8) \\ = 2672.5 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{for steady state}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_8 + (1-y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_8 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_8 - h_2} = \frac{670.38 - 226.53}{3335.3 - 226.53} = \mathbf{0.1427}$$

(b) The thermal efficiency is determined from

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) \\ = (3375.1 - 680.73) + (3479.1 - 2878.4) = 3295.1 \text{ kJ/kg}$$

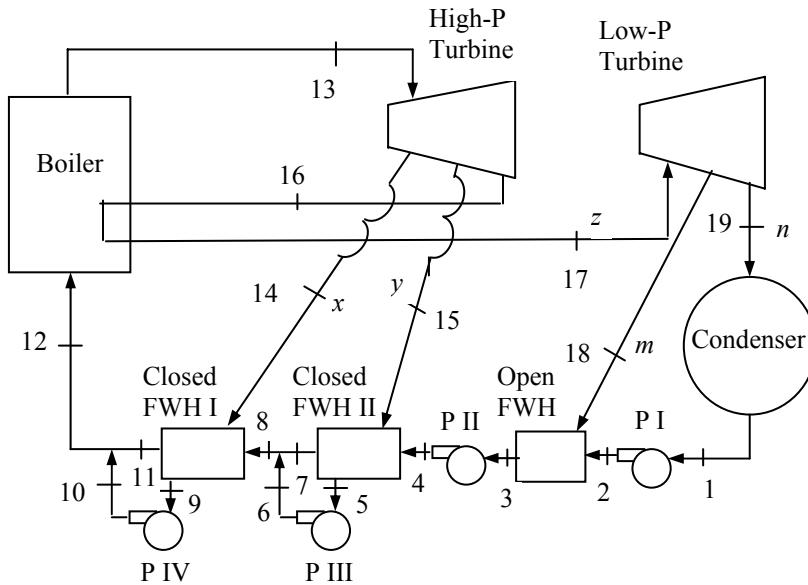

$$q_{\text{out}} = (1-y)(h_9 - h_1) = (1 - 0.1427)(2672.5 - 225.94) = 2097.2 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2097.2 \text{ kJ/kg}}{3295.1 \text{ kJ/kg}} = \mathbf{36.4\%}$$

10-104 A steam power plant operating on the ideal reheat-regenerative Rankine cycle with three feedwater heaters is considered. Various items for this system per unit of mass flow rate through the boiler are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The compression processes in the pumps and the expansion processes in the turbines are isentropic. Also, the state of water at the inlet of pumps is saturated liquid. Then, from the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = 168.75 \text{ kJ/kg}$$

$$h_{13} = 3423.1 \text{ kJ/kg}$$

$$h_2 = 168.84 \text{ kJ/kg}$$

$$h_{14} = 3204.5 \text{ kJ/kg}$$

$$h_3 = 417.51 \text{ kJ/kg}$$

$$h_{15} = 3063.6 \text{ kJ/kg}$$

$$h_4 = 419.28 \text{ kJ/kg}$$

$$h_{16} = 2871.0 \text{ kJ/kg}$$

$$h_5 = 884.46 \text{ kJ/kg}$$

$$h_{17} = 3481.3 \text{ kJ/kg}$$

$$h_6 = 885.86 \text{ kJ/kg}$$

$$h_{18} = 2891.5 \text{ kJ/kg}$$

$$h_9 = 1008.3 \text{ kJ/kg}$$

$$h_{19} = 2454.7 \text{ kJ/kg}$$

$$h_{10} = 1011.8 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure. Then,

$$\left. \begin{array}{l} P_7 = 1800 \text{ kPa} \\ T_7 = T_5 = 207.1^\circ\text{C} \end{array} \right\} h_7 = 884.91 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{11} = 3000 \text{ kPa} \\ T_{11} = T_9 = 233.9^\circ\text{C} \end{array} \right\} h_{11} = 1008.8 \text{ kJ/kg}$$

Enthalpies at other states and the fractions of steam extracted from the turbines can be determined from mass and energy balances on cycle components as follows:

Mass Balances:

$$x + y + z = 1$$

$$m + n = z$$

Open feedwater heater:

$$mh_{18} + nh_2 = zh_3$$

Closed feedwater heater-II:

$$zh_4 + yh_{15} = zh_7 + yh_5$$

Closed feedwater heater-I:

$$(y+z)h_8 + xh_{14} = (y+z)h_{11} + xh_9$$

Mixing chamber after closed feedwater heater II:

$$zh_7 + yh_6 = (y+z)h_8$$

Mixing chamber after closed feedwater heater I:

$$xh_{10} + (y+z)h_{11} = 1h_{12}$$

Substituting the values and solving the above equations simultaneously using EES, we obtain

$$h_8 = 885.08 \text{ kJ/kg}$$

$$h_{12} = 1009.0 \text{ kJ/kg}$$

$$x = \mathbf{0.05334}$$

$$y = \mathbf{0.1667}$$

$$z = 0.78000$$

$$m = \mathbf{0.07124}$$

$$n = \mathbf{0.70882}$$

Note that these values may also be obtained by a hand solution by using the equations above with some rearrangements and substitutions. Other results of the cycle are

$$w_{T,out,HP} = x(h_{13} - h_{14}) + y(h_{13} - h_{15}) + z(h_{13} - h_{16}) = \mathbf{502.3 \text{ kJ/kg}}$$

$$w_{T,out,LP} = m(h_{17} - h_{18}) + n(h_{17} - h_{19}) = \mathbf{769.6 \text{ kJ/kg}}$$

$$q_{in} = h_{13} - h_{12} + z(h_{17} - h_{16}) = \mathbf{2890 \text{ kJ/kg}}$$

$$q_{out} = n(h_{19} - h_1) = \mathbf{1620 \text{ kJ/kg}}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{1620}{2890} = 0.4394 = \mathbf{43.9\%}$$

10-105 The optimum bleed pressure for the open feedwater heater that maximizes the thermal efficiency of the cycle is to be determined using EES.

Analysis The EES program used to solve this problem as well as the solutions are given below.

10-106 A cogeneration plant is to produce power and process heat. There are two turbines in the cycle: a high-pressure turbine and a low-pressure turbine. The temperature, pressure, and mass flow rate of steam at the inlet of high-pressure turbine are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned} P_4 &= 1.4 \text{ MPa} \quad \left\{ \begin{array}{l} h_4 = h_g @ 1.4 \text{ MPa} = 2788.9 \text{ kJ/kg} \\ s_4 = s_g @ 1.4 \text{ MPa} = 6.4675 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \\ \text{sat. vapor} \quad & \\ P_5 &= 10 \text{ kPa} \quad \left\{ \begin{array}{l} x_{5s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.4675 - 0.6492}{7.4996} = 0.7758 \\ s_{5s} = s_4 \quad \left\{ \begin{array}{l} h_{5s} = h_f + x_{5s} h_{fg} \\ = 191.81 + (0.7758)(2392.1) = 2047.6 \text{ kJ/kg} \end{array} \right. \end{array} \right. \\ \eta_T &= \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T(h_4 - h_{5s}) \\ &= 2788.9 - (0.60)(2788.9 - 2047.6) \\ &= 2344.1 \text{ kJ/kg} \end{aligned}$$

and

$$\begin{aligned} w_{\text{turb,low}} &= h_4 - h_5 = 2788.9 - 2344.1 = 444.8 \text{ kJ/kg} \\ \dot{m}_{\text{low turb}} &= \frac{\dot{W}_{\text{turb,II}}}{w_{\text{turb,low}}} = \frac{800 \text{ kJ/s}}{444.8 \text{ kJ/kg}} = 1.799 \text{ kg/s} = 107.9 \text{ kg/min} \end{aligned}$$

Therefore ,

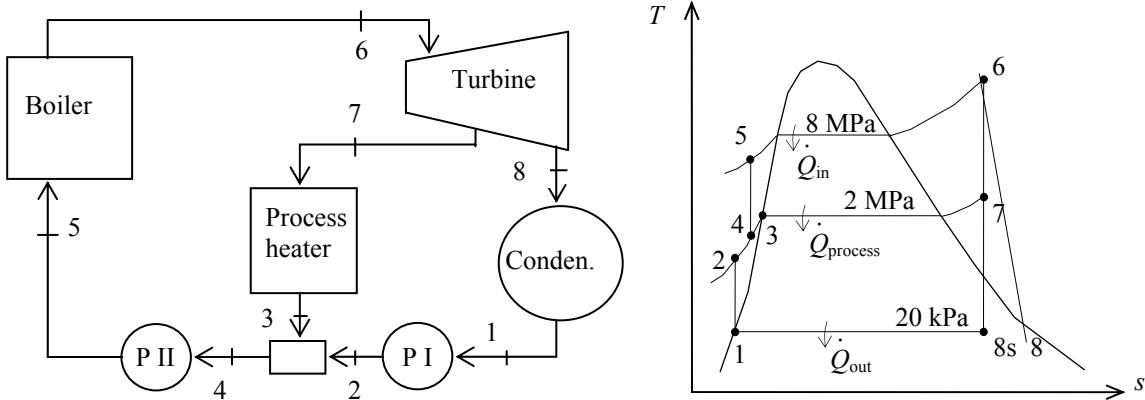

$$\begin{aligned} \dot{m}_{\text{total}} &= 1000 + 108 = 1108 \text{ kg/min} = \mathbf{18.47 \text{ kg/s}} \\ w_{\text{turb,high}} &= \frac{\dot{W}_{\text{turb,I}}}{\dot{m}_{\text{high,turb}}} = \frac{1000 \text{ kJ/s}}{18.47 \text{ kg/s}} = 54.15 \text{ kJ/kg} = h_3 - h_4 \\ h_3 &= w_{\text{turb,high}} + h_4 = 54.15 + 2788.9 = 2843.0 \text{ kJ/kg} \\ \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_{4s} = h_3 - (h_3 - h_4)/\eta_T \\ &= 2843.0 - (2843.0 - 2788.9)/(0.75) \\ &= 2770.8 \text{ kJ/kg} \\ P_{4s} &= 1.4 \text{ MPa} \quad \left\{ \begin{array}{l} x_{4s} = \frac{h_{4s} - h_f}{h_{fg}} = \frac{2770.8 - 829.96}{1958.9} = 0.9908 \\ s_{4s} = s_3 \quad \left\{ \begin{array}{l} s_{4s} = s_f + x_{4s} s_{fg} = 2.2835 + (0.9908)(4.1840) = 6.4289 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \end{array} \right. \end{aligned}$$

Then from the tables or the software, the turbine inlet temperature and pressure becomes

$$\begin{aligned} h_3 &= 2843.0 \text{ kJ/kg} \quad \left\{ \begin{array}{l} P_3 = \mathbf{2 \text{ MPa}} \\ s_3 = 6.4289 \text{ kJ/kg} \cdot \text{K} \quad \left\{ \begin{array}{l} T_3 = \mathbf{227.5^\circ C} \end{array} \right. \end{array} \right. \end{aligned}$$

10-107 A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The rate of process heat, the net power produced, and the utilization factor of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.001017 \text{ m}^3/\text{kg})(2000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.88 \\ &= 2.29 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 251.42 + 2.29 = 253.71 \text{ kJ/kg}$$

$$h_3 = h_f @ 2 \text{ MPa} = 908.47 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{m}_3 h_3 + \dot{m}_2 h_2 = \dot{m}_4 h_4$$

$$(4 \text{ kg/s})(908.47 \text{ kJ/kg}) + (11 - 4 \text{ kg/s})(253.71 \text{ kJ/kg}) = (11 \text{ kg/s})h_4 \longrightarrow h_4 = 491.81 \text{ kJ/kg}$$

$$\nu_4 \cong \nu_f @ h_f = 491.81 \text{ kJ/kg} = 0.001058 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII,in} &= \nu_4 (P_5 - P_4) / \eta_p \\ &= (0.001058 \text{ m}^3/\text{kg})(8000 - 2000 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.88 \\ &= 7.21 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII,in} = 491.81 + 7.21 = 499.02 \text{ kJ/kg}$$

$$\begin{cases} P_6 = 8 \text{ MPa} \\ T_6 = 500^\circ\text{C} \end{cases} \begin{cases} h_6 = 3399.5 \text{ kJ/kg} \\ s_6 = 6.7266 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\begin{cases} P_7 = 2 \text{ MPa} \\ s_7 = s_6 \end{cases} \begin{cases} h_{7s} = 3000.4 \text{ kJ/kg} \end{cases}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} \longrightarrow h_7 = h_6 - \eta_T (h_6 - h_{7s}) = 3399.5 - (0.88)(3399.5 - 3000.4) = 3048.3 \text{ kJ/kg}$$

$$\begin{cases} P_8 = 20 \text{ kPa} \\ s_8 = s_6 \end{cases} \begin{cases} h_{8s} = 2215.5 \text{ kJ/kg} \end{cases}$$

$$\eta_T = \frac{h_6 - h_8}{h_6 - h_{8s}} \longrightarrow h_8 = h_6 - \eta_T(h_6 - h_{8s}) = 3399.5 - (0.88)(3399.5 - 2215.5) = 2357.6 \text{ kJ/kg}$$

Then,

$$\dot{Q}_{\text{process}} = \dot{m}_7(h_7 - h_3) = (4 \text{ kg/s})(3048.3 - 908.47) \text{ kJ/kg} = \mathbf{8559 \text{ kW}}$$

(b) Cycle analysis:

$$\begin{aligned}\dot{W}_{T,\text{out}} &= \dot{m}_7(h_6 - h_7) + \dot{m}_8(h_6 - h_8) \\ &= (4 \text{ kg/s})(3399.5 - 3048.3) \text{ kJ/kg} + (7 \text{ kg/s})(3399.5 - 2357.6) \text{ kJ/kg} \\ &= 8698 \text{ kW}\end{aligned}$$

$$\dot{W}_{p,\text{in}} = \dot{m}_1 w_{pI,\text{in}} + \dot{m}_4 w_{pII,\text{in}} = (7 \text{ kg/s})(2.29 \text{ kJ/kg}) + (11 \text{ kg/s})(7.21 \text{ kJ/kg}) = 95 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{T,\text{out}} - \dot{W}_{p,\text{in}} = 8698 - 95 = \mathbf{8603 \text{ kW}}$$

(c) Then,

$$\dot{Q}_{\text{in}} = \dot{m}_5(h_6 - h_5) = (11 \text{ kg/s})(3399.5 - 499.02) = 31,905 \text{ kW}$$

and

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{8603 + 8559}{31,905} = 0.538 = \mathbf{53.8\%}$$

10-108E A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The thermal efficiency of the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable for Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (540 \text{ R})(10)^{0.4/1.4} = 1043 \text{ R}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\longrightarrow T_6 = T_5 + \frac{T_{6s} - T_5}{\eta_C}$$

$$= 540 + \frac{1043 - 540}{0.90} = 1099 \text{ R}$$

$$T_{8s} = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (2560 \text{ R}) \left(\frac{1}{10} \right)^{0.4/1.4} = 1326 \text{ R}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} = \frac{c_p(T_7 - T_8)}{c_p(T_7 - T_{8s})} \longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 2560 - (0.90)(2560 - 1326) \\ &= 1449 \text{ R} \end{aligned}$$

$$T_9 = T_{\text{sat}@800\text{ psia}} + 50 = 978.3 \text{ R} + 50 = 1028 \text{ R}$$

Fixing the states around the bottom steam cycle yields (Tables A-4E, A-5E, A-6E):

$$h_1 = h_{f@5\text{ psia}} = 130.18 \text{ Btu/lbm}$$

$$v_1 = v_{f@5\text{ psia}} = 0.01641 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lbm})(800 - 5)\text{psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 2.41 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 130.18 + 2.41 = 132.59 \text{ Btu/lbm}$$

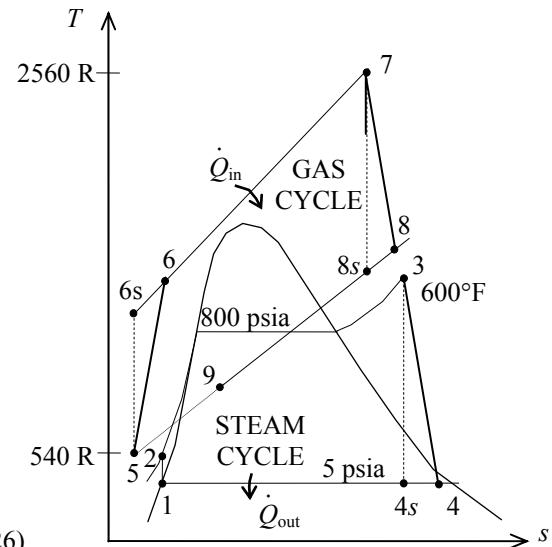

$$\begin{cases} P_3 = 800 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1270.9 \text{ Btu/lbm} \\ s_3 = 1.4866 \text{ Btu/lbm}\cdot\text{R} \end{cases}$$

$$\begin{cases} P_4 = 5 \text{ psia} \\ s_4 = s_3 \end{cases} \quad h_{4s} = 908.6 \text{ Btu/lbm}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1270.9 - (0.95)(1270.9 - 908.6) \\ &= 926.7 \text{ Btu/lbm} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned} w_{\text{net,gas cycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\ &= c_p(T_7 - T_8) - c_p(T_6 - T_5) \\ &= (0.240 \text{ Btu/lbm}\cdot\text{R})(2560 - 1449 - 1099 + 540)\text{R} \\ &= 132.5 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned}
 w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\
 &= (h_3 - h_4) - w_{P,\text{in}} \\
 &= (1270.9 - 926.7) - 2.41 \\
 &= 341.8 \text{ Btu/lbm}
 \end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(0.240)(1449 - 1028)}{1270.9 - 132.59} = 0.08876 \dot{m}_a$$

That is, 1 lbm of exhaust gases can heat only 0.08876 lbm of water. Then the heat input, the heat output and the thermal efficiency are

$$\begin{aligned}
 q_{\text{in}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_7 - T_6) = (0.240 \text{ Btu/lbm}\cdot\text{R})(2560 - 1099)\text{R} = 350.6 \text{ Btu/lbm} \\
 q_{\text{out}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_9 - T_5) + \frac{\dot{m}_w}{\dot{m}_a} (h_4 - h_1) \\
 &= 1 \times (0.240 \text{ Btu/lbm}\cdot\text{R})(1028 - 540)\text{R} + 0.08876 \times (926.7 - 130.18) \text{ Btu/lbm} \\
 &= 187.8 \text{ Btu/lbm} \\
 \eta_{\text{th}} &= 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{187.8}{350.6} = \mathbf{0.4643}
 \end{aligned}$$

10-109E A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The thermal efficiency of the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are

$c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (540 \text{ R})(10)^{0.4/1.4} = 1043 \text{ R}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\longrightarrow T_6 = T_5 + \frac{T_{6s} - T_5}{\eta_C}$$

$$= 540 + \frac{1043 - 540}{0.90} = 1099 \text{ R}$$

$$T_{8s} = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (2560 \text{ R}) \left(\frac{1}{10} \right)^{0.4/1.4} = 1326 \text{ R}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} = \frac{c_p(T_7 - T_8)}{c_p(T_7 - T_{8s})} \longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 2560 - (0.90)(2560 - 1326) \\ &= 1449 \text{ R} \end{aligned}$$

$$T_9 = T_{\text{sat}} @ 800 \text{ psia} + 50 = 978.3 \text{ R} + 50 = 1028 \text{ R}$$

Fixing the states around the bottom steam cycle yields (Tables A-4E, A-5E, A-6E):

$$h_1 = h_{f@10 \text{ psia}} = 161.25 \text{ Btu/lbm}$$

$$\nu_1 = \nu_{f@10 \text{ psia}} = 0.01659 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.01659 \text{ ft}^3/\text{lbm})(800 - 10) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 2.43 \text{ Btu/lbm} \end{aligned}$$

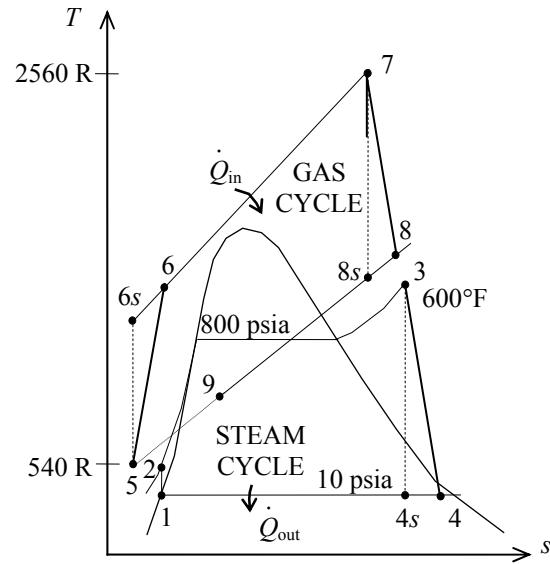

$$h_2 = h_1 + w_{p,\text{in}} = 161.25 + 2.43 = 163.7 \text{ Btu/lbm}$$

$$\begin{cases} P_3 = 800 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{cases} \quad \begin{cases} h_3 = 1270.9 \text{ Btu/lbm} \\ s_3 = 1.4866 \text{ Btu/lbm}\cdot\text{R} \end{cases}$$

$$\begin{cases} P_4 = 10 \text{ psia} \\ s_4 = s_3 \end{cases} \quad h_{4s} = 946.6 \text{ Btu/lbm}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1270.9 - (0.95)(1270.9 - 946.6) \\ &= 962.8 \text{ Btu/lbm} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned}
w_{\text{net, gas cycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\
&= c_p(T_7 - T_8) - c_p(T_6 - T_5) \\
&= (0.240 \text{ Btu/lbm}\cdot\text{R})(2560 - 1449 - 1099 + 540)\text{R} \\
&= 132.5 \text{ Btu/lbm}
\end{aligned}$$

$$\begin{aligned}
w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\
&= (h_3 - h_4) - w_{P,\text{in}} \\
&= (1270.9 - 962.8) - 2.43 \\
&= 305.7 \text{ Btu/lbm}
\end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(0.240)(1449 - 1028)}{1270.9 - 163.7} = 0.09126 \dot{m}_a$$

That is, 1 lbm of exhaust gases can heat only 0.09126 lbm of water. Then the heat input, the heat output and the thermal efficiency are

$$\begin{aligned}
q_{\text{in}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_7 - T_6) = (0.240 \text{ Btu/lbm}\cdot\text{R})(2560 - 1099)\text{R} = 350.6 \text{ Btu/lbm} \\
q_{\text{out}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_9 - T_5) + \frac{\dot{m}_w}{\dot{m}_a} (h_4 - h_1) \\
&= 1 \times (0.240 \text{ Btu/lbm}\cdot\text{R})(1028 - 540)\text{R} + 0.09126 \times (962.8 - 161.25) \text{ Btu/lbm} \\
&= 190.3 \text{ Btu/lbm}
\end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{190.3}{350.6} = \mathbf{0.4573}$$

When the condenser pressure is increased from 5 psia to 10 psia, the thermal efficiency is decreased from 0.4643 to 0.4573.

10-110E A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The cycle supplies a specified rate of heat to the buildings during winter. The mass flow rate of air and the net power output from the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis The mass flow rate of water is

$$\dot{m}_w = \frac{\dot{Q}_{\text{buildings}}}{h_4 - h_1} = \frac{2 \times 10^6 \text{ Btu/h}}{(962.8 - 161.25) \text{ Btu/lbm}} = 2495 \text{ lbm/h}$$

The mass flow rate of air is then

$$\dot{m}_a = \frac{\dot{m}_w}{0.09126} = \frac{2495}{0.09126} = 27,340 \text{ lbm/h}$$

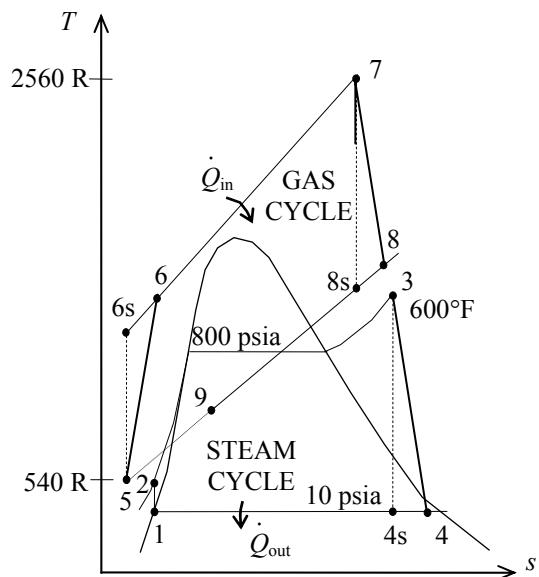

The power outputs from each cycle are

$$\begin{aligned} \dot{W}_{\text{net, gas cycle}} &= \dot{m}_a (w_{T,\text{out}} - w_{C,\text{in}}) \\ &= \dot{m}_a c_p (T_7 - T_8) - \dot{m}_a c_p (T_6 - T_5) \\ &= (27,340 \text{ lbm/h})(0.240 \text{ Btu/lbm}\cdot\text{R})(2560 - 1449 - 1099 + 540) \text{ R} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) \\ &= 1062 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{W}_{\text{net, steam cycle}} &= \dot{m}_a (w_{T,\text{out}} - w_{P,\text{in}}) \\ &= \dot{m}_a (h_3 - h_4 - w_{P,\text{in}}) \\ &= (2495 \text{ lbm/h})(1270.9 - 962.8 - 2.43) \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) \\ &= 224 \text{ kW} \end{aligned}$$

The net electricity production by this cycle is then

$$\dot{W}_{\text{net}} = 1062 + 224 = 1286 \text{ kW}$$

10-111 A combined gas-steam power plant is considered. The topping cycle is an ideal gas-turbine cycle and the bottoming cycle is an ideal reheat Rankine cycle. The mass flow rate of air in the gas-turbine cycle, the rate of total heat input, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) The analysis of gas cycle yields

$$T_7 = 310 \text{ K} \longrightarrow h_7 = 310.24 \text{ kJ/kg}$$

$$P_{r_7} = 1.5546$$

$$P_{r_8} = \frac{P_8}{P_7} P_{r_7} = (12)(1.5546) = 18.66 \longrightarrow h_8 = 630.18 \text{ kJ/kg}$$

$$T_9 = 1400 \text{ K} \longrightarrow h_9 = 1515.42 \text{ kJ/kg}$$

$$P_{r_9} = 450.5$$

$$P_{r_{10}} = \frac{P_{10}}{P_9} P_{r_9} = \left(\frac{1}{12}\right)(450.5) = 37.54 \longrightarrow h_{10} = 768.38 \text{ kJ/kg}$$

$$T_{11} = 520 \text{ K} \longrightarrow h_{11} = 523.63 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI,in} = v_1(P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(12,500 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 12.62 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,in} = 191.81 + 12.62 = 204.42 \text{ kJ/kg}$$

$$P_3 = 12.5 \text{ MPa} \quad h_3 = 3343.6 \text{ kJ/kg}$$

$$T_3 = 500^\circ\text{C} \quad s_3 = 6.4651 \text{ kJ/kg} \cdot \text{K}$$

$$P_4 = 2.5 \text{ MPa} \quad h_4 = 2909.6 \text{ kJ/kg}$$

$$s_4 = s_3 \quad h_5 = 3574.4 \text{ kJ/kg}$$

$$T_5 = 550^\circ\text{C} \quad s_5 = 7.4653 \text{ kJ/kg} \cdot \text{K}$$

$$P_6 = 10 \text{ kPa} \quad x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.4653 - 0.6492}{7.4996} = 0.9089$$

$$s_6 = s_5 \quad h_6 = h_f + x_6 h_{fg} = 191.81 + (0.9089)(2392.1) = 2365.8 \text{ kJ/kg}$$

Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{in} = \dot{E}_{out} \longrightarrow \sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_3 - h_2) = \dot{m}_{air} (h_{10} - h_{11})$$

$$\dot{m}_{air} = \frac{h_3 - h_2}{h_{10} - h_{11}} \dot{m}_s = \frac{3343.6 - 204.42}{768.38 - 523.63} (12 \text{ kg/s}) = 153.9 \text{ kg/s}$$

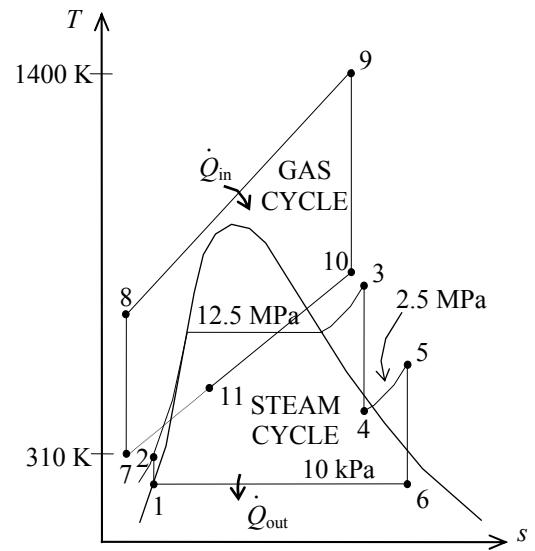

(b) The rate of total heat input is

$$\begin{aligned} \dot{Q}_{in} &= \dot{Q}_{air} + \dot{Q}_{reheat} = \dot{m}_{air} (h_9 - h_8) + \dot{m}_{reheat} (h_5 - h_4) \\ &= (153.9 \text{ kg/s})(1515.42 - 630.18) \text{ kJ/kg} + (12 \text{ kg/s})(3574.4 - 2909.6) \text{ kJ/kg} \\ &= 144,200 \text{ kW} \\ &\approx \mathbf{1.44 \times 10^5 \text{ kW}} \end{aligned}$$

(c) The rate of heat rejection and the thermal efficiency are then

$$\begin{aligned} \dot{Q}_{out} &= \dot{Q}_{out,air} + \dot{Q}_{out,steam} = \dot{m}_{air} (h_{11} - h_7) + \dot{m}_s (h_6 - h_1) \\ &= (153.9 \text{ kg/s})(523.63 - 310.24) \text{ kJ/kg} + (12 \text{ kg/s})(2365.8 - 191.81) \text{ kJ/kg} \\ &= 58,930 \text{ kW} \end{aligned}$$

$$\eta_{th} = 1 - \frac{\dot{Q}_{out}}{\dot{Q}_{in}} = 1 - \frac{58,930 \text{ kW}}{144,200 \text{ kW}} = 0.5913 = \mathbf{59.1\%}$$

10-112 A combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal reheat Rankine cycle. The mass flow rate of air in the gas-turbine cycle, the rate of total heat input, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) The analysis of gas cycle yields (Table A-17)

$$T_7 = 290 \text{ K} \longrightarrow h_7 = 290.16 \text{ kJ/kg}$$

$$P_{r_7} = 1.2311$$

$$P_{r_{8s}} = \frac{P_{8s}}{P_7} P_{r_7} = (8)(1.2311) = 9.849 \longrightarrow h_{8s} = 526.12 \text{ kJ/kg}$$

$$\eta_C = \frac{h_8 - h_7}{h_{8s} - h_7} \longrightarrow h_8 = h_7 + (h_{8s} - h_7)/\eta_C$$

$$= 290.16 + (526.12 - 290.16)/(0.80)$$

$$= 585.1 \text{ kJ/kg}$$

$$T_9 = 1400 \text{ K} \longrightarrow h_9 = 1515.42 \text{ kJ/kg}$$

$$P_{r_9} = 450.5$$

$$P_{r_{10s}} = \frac{P_{10s}}{P_9} P_{r_9} = \left(\frac{1}{8}\right)(450.5) = 56.3 \longrightarrow h_{10s} = 860.35 \text{ kJ/kg}$$

$$\eta_T = \frac{h_9 - h_{10s}}{h_9 - h_{10s}} \longrightarrow h_{10s} = h_9 - \eta_T(h_9 - h_{10s})$$

$$= 1515.42 - (0.85)(1515.42 - 860.35)$$

$$= 958.4 \text{ kJ/kg}$$

$$T_{11} = 520 \text{ K} \longrightarrow h_{11} = 523.63 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pl,in} = v_1(P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 15.14 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pl,in} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$P_3 = 15 \text{ MPa} \quad h_3 = 3157.9 \text{ kJ/kg}$$

$$T_3 = 450^\circ\text{C} \quad s_3 = 6.1428 \text{ kJ/kg} \cdot \text{K}$$

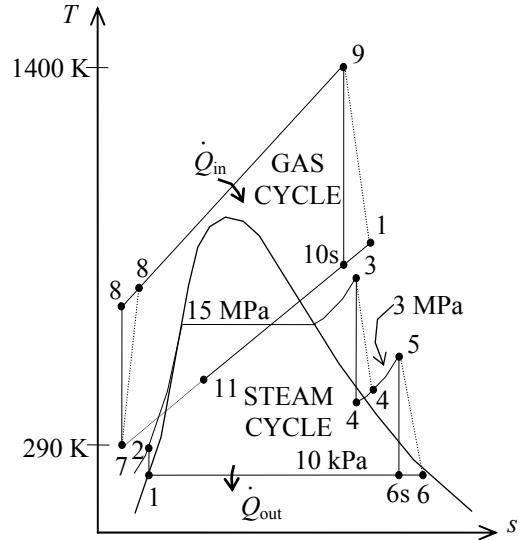

$$P_4 = 3 \text{ MPa} \quad x_{4s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.1434 - 2.6454}{3.5402} = 0.9880$$

$$s_{4s} = s_3 \quad h_{4s} = h_f + x_{4s}h_{fg} = 1008.3 + (0.9879)(1794.9) = 2781.7 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s})$$

$$= 3157.9 - (0.85)(3157.9 - 2781.7)$$

$$= 2838.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 3 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} h_5 = 3457.2 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ s_{6s} = s_5 \end{array} \right\} \begin{aligned} x_{6s} &= \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.2359 - 0.6492}{7.4996} = 0.8783 \\ h_{6s} &= h_f + x_{6s}h_{fg} = 191.81 + (0.8782)(2392.1) = 2292.8 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) \\ &= 3457.2 - (0.85)(3457.2 - 2292.8) \\ &= 2467.5 \text{ kJ/kg} \end{aligned}$$

Noting that $\dot{Q} \equiv \dot{W} \equiv \Delta ke \equiv \Delta pe \equiv 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \xrightarrow{\text{d}0(\text{steady})} = 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s(h_3 - h_2) = \dot{m}_{air}(h_{10} - h_{11}) \\ \dot{m}_{air} &= \frac{h_3 - h_2}{h_{10} - h_{11}} \dot{m}_s = \frac{3157.9 - 206.95}{958.4 - 523.63} (30 \text{ kg/s}) = \mathbf{203.6 \text{ kg/s}} \end{aligned}$$

$$(b) \quad \dot{Q}_{in} = \dot{Q}_{air} + \dot{Q}_{reheat} = \dot{m}_{air}(h_9 - h_8) + \dot{m}_{reheat}(h_5 - h_4) \\ = (203.6 \text{ kg/s})(1515.42 - 585.1) \text{ kJ/kg} + (30 \text{ kg/s})(3457.2 - 2838.1) \text{ kJ/kg} \\ = \mathbf{207,986 \text{ kW}}$$

$$(c) \quad \dot{Q}_{out} = \dot{Q}_{out,air} + \dot{Q}_{out,steam} = \dot{m}_{air}(h_{11} - h_7) + \dot{m}_s(h_6 - h_1) \\ = (203.6 \text{ kg/s})(523.63 - 290.16) \text{ kJ/kg} + (30 \text{ kg/s})(2467.5 - 191.81) \text{ kJ/kg} \\ = 115,805 \text{ kW}$$

$$\eta_{th} = 1 - \frac{\dot{Q}_{out}}{\dot{Q}_{in}} = 1 - \frac{115,805 \text{ kW}}{207,986 \text{ kW}} = \mathbf{44.3\%}$$

10-113 A Rankine steam cycle modified with two closed feedwater heaters and one open feed water heater is considered. The $T-s$ diagram for the ideal cycle is to be sketched. The fraction of mass extracted for the open feedwater heater y and the cooling water flow temperature rise are to be determined. Also, the rate of heat rejected in the condenser and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 20 \text{ kPa} = 251 \text{ kJ/kg}$$

$$h_{15} = h_3 = h_{14} = h_f @ 140 \text{ kPa} = 458 \text{ kJ/kg}$$

$$h_4 = h_f @ 620 \text{ kPa} = 676 \text{ kJ/kg}$$

$$h_6 = h_{12} = h_f @ 1910 \text{ kPa} = 898 \text{ kJ/kg}$$

An energy balance on the open feedwater heater gives

$$yh_9 + (1-y)h_3 = h_4$$

where z is the fraction of steam extracted from the low-pressure turbine. Solving for z ,

$$y = \frac{h_4 - h_3}{h_9 - h_3} = \frac{676 - 458}{3154 - 458} = \mathbf{0.08086}$$

(c) An energy balance on the condenser gives

$$\dot{m}_7 [(1-w-y-z)h_{11} + (w+z)h_{15} - (1-y)h_1] = \dot{m}_w (h_{w2} - h_{w1}) = \dot{m}_w c_{pw} \Delta T_w$$

Solving for the temperature rise of cooling water, and substituting with correct units,

$$\begin{aligned} \Delta T_w &= \frac{\dot{m}_7 [(1-w-y-z)h_{11} + (w+z)h_{15} - (1-y)h_1]}{\dot{m}_w c_{pw}} \\ &= \frac{(100)[(1-0.0830-0.08086-0.0655)(2478)+(0.0830+0.0655)(458)-(1-0.08086)(251)]}{(4200)(4.18)} \\ &= \mathbf{9.95^\circ C} \end{aligned}$$

(d) The rate of heat rejected in the condenser is

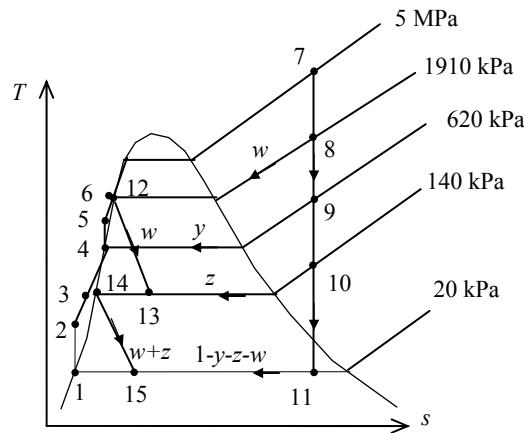

$$\dot{Q}_{\text{out}} = \dot{m}_w c_{pw} \Delta T_w = (4200 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(9.95^\circ\text{C}) = \mathbf{174,700 \text{ kW}}$$

The rate of heat input in the boiler is

$$\dot{Q}_{\text{in}} = \dot{m}(h_7 - h_6) = (100 \text{ kg/s})(3900 - 898) \text{ kJ/kg} = 300,200 \text{ kW}$$

The thermal efficiency is then

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{174,700 \text{ kW}}{300,200 \text{ kW}} = 0.418 = \mathbf{41.8\%}$$

10-114 A Rankine steam cycle modified for reheat, two closed feedwater heaters and a process heater is considered. The $T-s$ diagram for the ideal cycle is to be sketched. The fraction of mass, w , that is extracted for the closed feedwater heater is to be determined. Also, the mass flow rate through the boiler, the rate of process heat supplied, and the utilization efficiency of this cogeneration plant are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 20 \text{ kPa} = 251.4 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.00102 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{pl,in}} &= v_1(P_2 - P_1) \\ &= (0.00102 \text{ m}^3/\text{kg})(5000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.1 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{pl,in}} = 251.4 + 5.1 = 256.5 \text{ kJ/kg}$$

$$h_{13} = h_{12} = h_f @ 245 \text{ kPa} = 533 \text{ kJ/kg}$$

$$h_4 = h_{15} = h_{14} = h_f @ 1400 \text{ kPa} = 830 \text{ kJ/kg}$$

$$h_3 = h_{16} = h_f @ 150 \text{ kPa} = 467 \text{ kJ/kg}$$

An energy balance on the closed feedwater heater gives

$$1h_2 + wh_{10} + zh_{13} + yh_{15} = 1h_3 + (y + z + w)h_{16}$$

where w is the fraction of steam extracted from the low-pressure turbine. Solving for z ,

$$\begin{aligned} w &= \frac{(h_3 - h_2) + (y + z)h_{16} - zh_{13} - yh_{15}}{h_{10} - h_{16}} \\ &= \frac{(467 - 256.5) + (0.1160 + 0.15)(467) - (0.15)(533) - (0.1160)(830)}{3023 - 467} \\ &= \mathbf{0.0620} \end{aligned}$$

(c) The work output from the turbines is

$$\begin{aligned} w_{T,\text{out}} &= h_5 - yh_6 - (1-y)h_7 + (1-y)h_8 - zh_9 - wh_{10} - (1-y-z-w)h_{11} \\ &= 3894 - (0.1160)(3400) - (1-0.1160)(3349) \\ &\quad + (1-0.1160)(3692) - (0.15)(3154) - (0.0620)(3023) - (1-0.1160-0.15-0.0620)(2620) \\ &= 1381.6 \text{ kJ/kg} \end{aligned}$$

The net work output from the cycle is

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 1381.6 - 5.1 = 1376.5 \text{ kJ/kg}$$

The mass flow rate through the boiler is

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{300,000 \text{ kW}}{1376.5 \text{ kJ/kg}} = \mathbf{217.9 \text{ kg/s}}$$

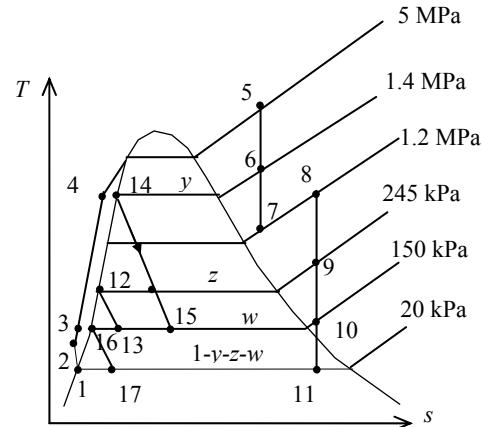

The rate of heat input in the boiler is

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}(h_5 - h_4) + (1-y)\dot{m}(h_8 - h_7) \\ &= (217.9 \text{ kg/s})(3894 - 830) \text{ kJ/kg} + (1-0.1160)(217.9 \text{ kg/s})(3692 - 3349) \text{ kJ/kg} \\ &= 733,700 \text{ kW} \end{aligned}$$

The rate of process heat and the utilization efficiency of this cogeneration plant are

$$\dot{Q}_{\text{process}} = z\dot{m}(h_9 - h_{12}) = (0.15)(217.9 \text{ kg/s})(3154 - 533) \text{ kJ/kg} = \mathbf{85,670 \text{ kW}}$$

$$\epsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{(300,000 + 85,670) \text{ kW}}{733,700 \text{ kW}} = 0.526 = \mathbf{52.6\%}$$

10-115 The effect of the condenser pressure on the performance a simple ideal Rankine cycle is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-119 It is to be demonstrated that the thermal efficiency of a combined gas-steam power plant η_{cc} can be expressed as $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$ where $\eta_g = W_g / Q_{in}$ and $\eta_s = W_s / Q_{g,out}$ are the thermal efficiencies of the gas and steam cycles, respectively, and the efficiency of a combined cycle is to be obtained.

Analysis The thermal efficiencies of gas, steam, and combined cycles can be expressed as

$$\eta_{cc} = \frac{W_{total}}{Q_{in}} = 1 - \frac{Q_{out}}{Q_{in}}$$

$$\eta_g = \frac{W_g}{Q_{in}} = 1 - \frac{Q_{g,out}}{Q_{in}}$$

$$\eta_s = \frac{W_s}{Q_{g,out}} = 1 - \frac{Q_{out}}{Q_{g,out}}$$

where Q_{in} is the heat supplied to the gas cycle, where Q_{out} is the heat rejected by the steam cycle, and where $Q_{g,out}$ is the heat rejected from the gas cycle and supplied to the steam cycle.

Using the relations above, the expression $\eta_g + \eta_s - \eta_g \eta_s$ can be expressed as

$$\begin{aligned}\eta_g + \eta_s - \eta_g \eta_s &= \left(1 - \frac{Q_{g,out}}{Q_{in}}\right) + \left(1 - \frac{Q_{out}}{Q_{g,out}}\right) - \left(1 - \frac{Q_{g,out}}{Q_{in}}\right)\left(1 - \frac{Q_{out}}{Q_{g,out}}\right) \\ &= 1 - \frac{Q_{g,out}}{Q_{in}} + 1 - \frac{Q_{out}}{Q_{g,out}} - 1 + \frac{Q_{g,out}}{Q_{in}} + \frac{Q_{out}}{Q_{g,out}} - \frac{Q_{out}}{Q_{in}} \\ &= 1 - \frac{Q_{out}}{Q_{in}} \\ &= \eta_{cc}\end{aligned}$$

Therefore, the proof is complete. Using the relation above, the thermal efficiency of the given combined cycle is determined to be

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = 0.4 + 0.30 - 0.40 \times 0.30 = \mathbf{0.58}$$

10-120 The thermal efficiency of a combined gas-steam power plant η_{cc} can be expressed in terms of the thermal efficiencies of the gas and the steam turbine cycles as $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$. It is to be shown that the value of η_{cc} is greater than either of η_g or η_s .

Analysis By factoring out terms, the relation $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$ can be expressed as

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = \eta_g + \underbrace{\eta_s(1 - \eta_g)}_{\substack{\text{Positive since} \\ \eta_g < 1}} > \eta_g$$

$$\text{or } \eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = \eta_s + \underbrace{\eta_g(1 - \eta_s)}_{\substack{\text{Positive since} \\ \eta_s < 1}} > \eta_s$$

Thus we conclude that the combined cycle is more efficient than either of the gas turbine or steam turbine cycles alone.

10-121 It is to be shown that the exergy destruction associated with a simple ideal Rankine cycle can be expressed as $x_{\text{destroyed}} = q_{\text{in}} (\eta_{\text{th,Carnot}} - \eta_{\text{th}})$, where η_{th} is efficiency of the Rankine cycle and $\eta_{\text{th,Carnot}}$ is the efficiency of the Carnot cycle operating between the same temperature limits.

Analysis The exergy destruction associated with a cycle is given on a unit mass basis as

$$x_{\text{destroyed}} = T_0 \sum \frac{q_R}{T_R}$$

where the direction of q_{in} is determined with respect to the reservoir (positive if to the reservoir and negative if from the reservoir). For a cycle that involves heat transfer only with a source at T_H and a sink at T_0 , the irreversibility becomes

$$\begin{aligned} x_{\text{destroyed}} &= T_0 \left(\frac{q_{\text{out}}}{T_0} - \frac{q_{\text{in}}}{T_H} \right) = q_{\text{out}} - \frac{T_0}{T_H} q_{\text{in}} = q_{\text{in}} \left(\frac{q_{\text{out}}}{q_{\text{in}}} - \frac{T_0}{T_H} \right) \\ &= q_{\text{in}} [(1 - \eta_{\text{th}}) - (1 - \eta_{\text{th,C}})] = q_{\text{in}} (\eta_{\text{th,C}} - \eta_{\text{th}}) \end{aligned}$$

Fundamentals of Engineering (FE) Exam Problems

10-122 Consider a simple ideal Rankine cycle. If the condenser pressure is lowered while keeping turbine inlet state the same, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the cycle efficiency will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the pump work input will decrease.

Answer (b) the amount of heat rejected will decrease.

10-123 Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the steam is superheated to a higher temperature, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the cycle efficiency will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the amount of heat input will decrease.

Answer (d) the moisture content at turbine exit will decrease.

10-124 Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures . If the cycle is modified with reheating, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the pump work input will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the amount of heat input will decrease.

Answer (d) the moisture content at turbine exit will decrease.

10-125 Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures . If the cycle is modified with regeneration that involves one open feed water heater, (select the correct statement per unit mass of steam flowing through the boiler)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will increase.
- (c) the cycle thermal efficiency will decrease.
- (d) the quality of steam at turbine exit will decrease.
- (e) the amount of heat input will increase.

Answer (a) the turbine work output will decrease.

10-126 Consider a steady-flow Carnot cycle with water as the working fluid executed under the saturation dome between the pressure limits of 3 MPa and 10 kPa. Water changes from saturated liquid to saturated vapor during the heat addition process. The net work output of this cycle is

- (a) 666 kJ/kg (b) 888 kJ/kg (c) 1040 kJ/kg (d) 1130 kJ/kg (e) 1440 kJ/kg

Answer (a) 666 kJ/kg

```

10-134 Consider a cogeneration power plant modified with regeneration. Steam enters the turbine at 6 MPa and 450°C at a rate of 20 kg/s and expands to a pressure of 0.4 MPa. At this pressure, 60% of the steam is extracted from the turbine, and the remainder expands to a pressure of 10 kPa. Part of the extracted steam is used to heat feedwater in an open feedwater heater. The rest of the extracted steam is used for process heating and leaves the process heater as a saturated liquid at 0.4 MPa. It is subsequently mixed with the feedwater leaving the feedwater heater, and the mixture is pumped to the boiler pressure. The steam in the condenser is cooled and condensed by the cooling water from a nearby river, which enters the adiabatic condenser at a rate of 463 kg/s.

1. The total power output of the turbine is

- (a) 17.0 MW (b) 8.4 MW (c) 12.2 MW (d) 20.0 MW (e) 3.4 MW

Answer (a) 17.0 MW

2. The temperature rise of the cooling water from the river in the condenser is

- (a) 8.0°C (b) 5.2°C (c) 9.6°C (d) 12.9°C (e) 16.2°C

Answer (a) 8.0°C

3. The mass flow rate of steam through the process heater is

- (a) 1.6 kg/s (b) 3.8 kg/s (c) 5.2 kg/s (d) 7.6 kg/s (e) 10.4 kg/s

Answer (e) 10.4 kg/s

4. The rate of heat supply from the process heater per unit mass of steam passing through it is

- (a) 246 kJ/kg (b) 893 kJ/kg (c) 1344 kJ/kg (d) 1891 kJ/kg (e) 2060 kJ/kg

Answer (e) 2060 kJ/kg

5. The rate of heat transfer to the steam in the boiler is

- (a) 26.0 MJ/s (b) 53.8 MJ/s (c) 39.5 MJ/s (d) 62.8 MJ/s (e) 125.4 MJ/s

Answer (b) 53.8 MJ/s

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

Note: The solution given below also evaluates all enthalpies given on the figure.

The Reversed Carnot Cycle

11-1C The reversed Carnot cycle serves as a standard against which actual refrigeration cycles can be compared. Also, the COP of the reversed Carnot cycle provides the upper limit for the COP of a refrigeration cycle operating between the specified temperature limits.

11-2C Because the compression process involves the compression of a liquid-vapor mixture which requires a compressor that will handle two phases, and the expansion process involves the expansion of high-moisture content refrigerant.

11-3 A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The coefficient of performance, the amount of heat absorbed from the refrigerated space, and the net work input are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = 40^\circ\text{C} = 313\text{ K}$ and $T_L = T_{\text{sat}} @ 100\text{ kPa} = -26.37^\circ\text{C} = 246.6\text{ K}$, the COP of this Carnot refrigerator is determined from

$$\text{COP}_{R,C} = \frac{1}{T_H/T_L - 1} = \frac{1}{(313\text{ K})/(246.6\text{ K}) - 1} = 3.72$$

(b) From the refrigerant tables (Table A-11),

$$h_3 = h_g @ 40^\circ\text{C} = 271.27\text{ kJ/kg}$$

$$h_4 = h_f @ 40^\circ\text{C} = 108.26\text{ kJ/kg}$$

Thus,

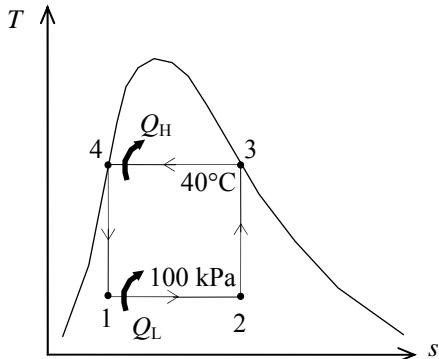

$$q_H = h_3 - h_4 = 271.27 - 108.26 = 163.0\text{ kJ/kg}$$

and

$$\frac{q_H}{q_L} = \frac{T_H}{T_L} \longrightarrow q_L = \frac{T_L}{T_H} q_H = \left(\frac{246.6\text{ K}}{313\text{ K}} \right) (163.0\text{ kJ/kg}) = 128.4\text{ kJ/kg}$$

(c) The net work input is determined from

$$w_{\text{net}} = q_H - q_L = 163.0 - 128.4 = 34.6\text{ kJ/kg}$$

11-4E A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The coefficient of performance, the quality at the beginning of the heat-absorption process, and the net work input are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = T_{\text{sat} @ 90 \text{ psia}} = 72.78^\circ\text{F} = 532.8 \text{ R}$ and $T_L = T_{\text{sat} @ 30 \text{ psia}} = 15.37^\circ\text{F} = 475.4 \text{ R}$.

$$\text{COP}_{\text{R,C}} = \frac{1}{T_H / T_L - 1} = \frac{1}{(532.8 \text{ R}) / (475.4 \text{ R}) - 1} = \mathbf{8.28}$$

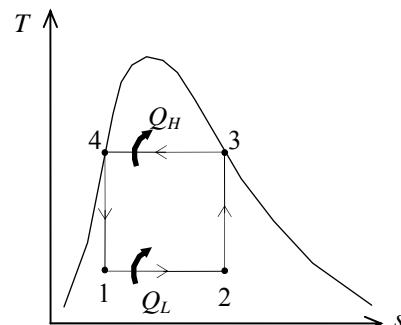

(b) Process 4-1 is isentropic, and thus

$$\begin{aligned}s_1 &= s_4 = (s_f + x_4 s_{fg})_{@ 90 \text{ psia}} = 0.07481 + (0.05)(0.14525) \\ &= 0.08207 \text{ Btu/lbm}\cdot\text{R}\end{aligned}$$

$$x_1 = \left(\frac{s_1 - s_f}{s_{fg}} \right)_{@ 30 \text{ psia}} = \frac{0.08207 - 0.03793}{0.18589} = \mathbf{0.2374}$$

(c) Remembering that on a T - s diagram the area enclosed represents the net work, and $s_3 = s_g @ 90 \text{ psia} = 0.22006 \text{ Btu/lbm}\cdot\text{R}$,

$$w_{\text{net,in}} = (T_H - T_L)(s_3 - s_4) = (72.78 - 15.37)(0.22006 - 0.08207) \text{ Btu/lbm}\cdot\text{R} = \mathbf{7.92 \text{ Btu/lbm}}$$

Ideal and Actual Vapor-Compression Refrigeration Cycles

11-5C Yes; the throttling process is an internally irreversible process.

11-6C To make the ideal vapor-compression refrigeration cycle more closely approximate the actual cycle.

11-7C No. Assuming the water is maintained at 10°C in the evaporator, the evaporator pressure will be the saturation pressure corresponding to this temperature, which is 1.2 kPa. It is not practical to design refrigeration or air-conditioning devices that involve such extremely low pressures.

11-8C Allowing a temperature difference of 10°C for effective heat transfer, the condensation temperature of the refrigerant should be 25°C. The saturation pressure corresponding to 25°C is 0.67 MPa. Therefore, the recommended pressure would be 0.7 MPa.

11-9C The area enclosed by the cyclic curve on a *T-s* diagram represents the net work input for the reversed Carnot cycle, but not so for the ideal vapor-compression refrigeration cycle. This is because the latter cycle involves an irreversible process for which the process path is not known.

11-10C The cycle that involves saturated liquid at 30°C will have a higher COP because, judging from the *T-s* diagram, it will require a smaller work input for the same refrigeration capacity.

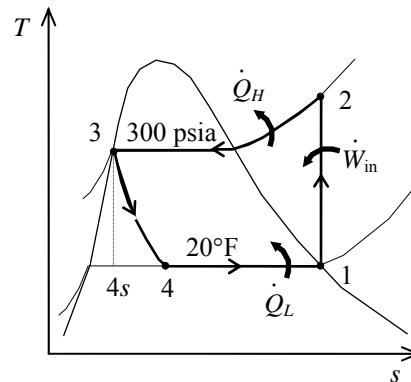

11-11C The minimum temperature that the refrigerant can be cooled to before throttling is the temperature of the sink (the cooling medium) since heat is transferred from the refrigerant to the cooling medium.

11-12E A refrigerator operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The increase in the COP if the throttling process were replaced by an isentropic expansion is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\begin{aligned} T_1 &= 20^{\circ}\text{F} \quad h_1 = h_g @ 20^{\circ}\text{F} = 105.98 \text{ Btu/lbm} \\ \text{sat. vapor} \quad s_1 &= s_g @ 20^{\circ}\text{F} = 0.22341 \text{ Btu/lbm}\cdot\text{R} \\ P_2 &= 300 \text{ psia} \quad h_2 = 125.68 \text{ Btu/lbm} \\ s_2 = s_1 & \\ P_3 &= 300 \text{ psia} \quad h_3 = h_f @ 300 \text{ psia} = 66.339 \text{ Btu/lbm} \\ \text{sat. liquid} \quad s_3 &= s_f @ 300 \text{ psia} = 0.12715 \text{ Btu/lbm}\cdot\text{R} \\ h_4 &\approx h_3 = 66.339 \text{ Btu/lbm} \quad (\text{throttling}) \\ T_4 &= 20^{\circ}\text{F} \quad h_{4s} = 59.80 \text{ Btu/lbm} \quad (\text{isentropic expansion}) \\ s_4 = s_3 & \end{aligned}$$

The COP of the refrigerator for the throttling case is

$$\text{COP}_R = \frac{q_L}{w_{in}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{105.98 - 66.339}{125.68 - 105.98} = \mathbf{2.012}$$

The COP of the refrigerator for the isentropic expansion case is

$$\text{COP}_R = \frac{q_L}{w_{in}} = \frac{h_1 - h_{4s}}{h_2 - h_1} = \frac{105.98 - 59.80}{125.68 - 105.98} = \mathbf{2.344}$$

The increase in the COP by isentropic expansion is **16.5%**.

11-13 An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP and the power requirement are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 4^\circ\text{C} = 252.77 \text{ kJ/kg} \\ s_1 = s_g @ 4^\circ\text{C} = 0.92927 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = 1 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 275.29 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1 \text{ MPa} = 107.32 \text{ kJ/kg}$$

$$h_4 \equiv h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is

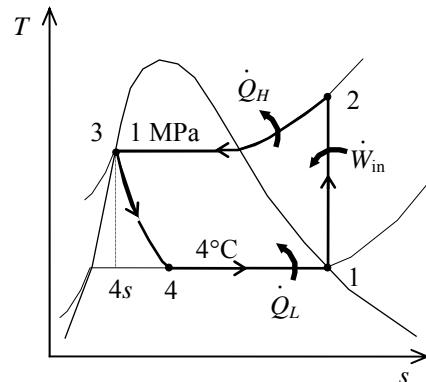

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{400 \text{ kJ/s}}{(252.77 - 107.32) \text{ kJ/kg}} = 2.750 \text{ kg/s}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (2.750 \text{ kg/s})(275.29 - 252.77) \text{ kJ/kg} = \mathbf{61.93 \text{ kW}}$$

The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{400 \text{ kW}}{61.93 \text{ kW}} = \mathbf{6.46}$$

11-14 An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the rate of heat rejection to the environment, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\begin{aligned} P_1 = 120 \text{ kPa} \\ \text{sat. vapor} \end{aligned} \left\{ \begin{array}{l} h_1 = h_g @ 120 \text{ kPa} = 236.97 \text{ kJ/kg} \\ s_1 = s_g @ 120 \text{ kPa} = 0.94779 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\begin{aligned} P_2 = 0.7 \text{ MPa} \\ s_2 = s_1 \end{aligned} \left\{ \begin{array}{l} h_2 = 273.50 \text{ kJ/kg} (T_2 = 34.95^\circ\text{C}) \end{array} \right.$$

$$\begin{aligned} P_3 = 0.7 \text{ MPa} \\ \text{sat. liquid} \end{aligned} \left\{ \begin{array}{l} h_3 = h_f @ 0.7 \text{ MPa} = 88.82 \text{ kJ/kg} \end{array} \right.$$

$$h_4 \approx h_3 = 88.82 \text{ kJ/kg} \text{ (throttling)}$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.05 \text{ kg/s})(236.97 - 88.82) \text{ kJ/kg} = \mathbf{7.41 \text{ kW}}$$

and

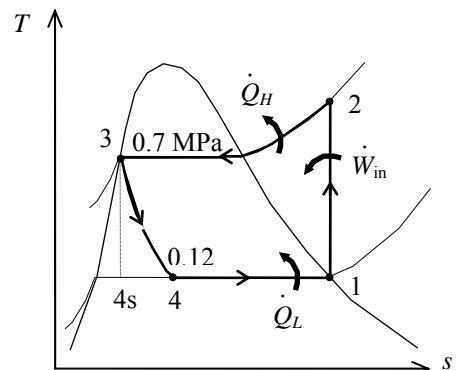

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.05 \text{ kg/s})(273.50 - 236.97) \text{ kJ/kg} = \mathbf{1.83 \text{ kW}}$$

(b) The rate of heat rejection to the environment is determined from

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{\text{in}} = 7.41 + 1.83 = \mathbf{9.23 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{7.41 \text{ kW}}{1.83 \text{ kW}} = \mathbf{4.06}$$

11-15 An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the rate of heat rejection to the environment, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\begin{aligned} P_1 = 120 \text{ kPa} \\ \text{sat. vapor} \end{aligned} \left\{ \begin{array}{l} h_1 = h_g @ 120 \text{ kPa} = 236.97 \text{ kJ/kg} \\ s_1 = s_g @ 120 \text{ kPa} = 0.94779 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\begin{aligned} P_2 = 0.9 \text{ MPa} \\ s_2 = s_1 \end{aligned} \left\{ \begin{array}{l} h_2 = 278.93 \text{ kJ/kg} (T_2 = 44.45^\circ\text{C}) \end{array} \right.$$

$$\begin{aligned} P_3 = 0.9 \text{ MPa} \\ \text{sat. liquid} \end{aligned} \left\{ \begin{array}{l} h_3 = h_f @ 0.9 \text{ MPa} = 101.61 \text{ kJ/kg} \end{array} \right.$$

$$h_4 \approx h_3 = 101.61 \text{ kJ/kg} \text{ (throttling)}$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.05 \text{ kg/s})(236.97 - 101.61) \text{ kJ/kg} = \mathbf{6.77 \text{ kW}}$$

and

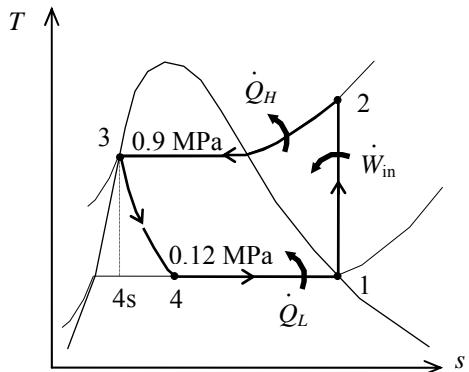

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.05 \text{ kg/s})(278.93 - 236.97) \text{ kJ/kg} = \mathbf{2.10 \text{ kW}}$$

(b) The rate of heat rejection to the environment is determined from

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{\text{in}} = 6.77 + 2.10 = \mathbf{8.87 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{6.77 \text{ kW}}{2.10 \text{ kW}} = \mathbf{3.23}$$

11-16 An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The throttling valve in the cycle is replaced by an isentropic turbine. The percentage increase in the COP and in the rate of heat removal from the refrigerated space due to this replacement are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis If the throttling valve in the previous problem is replaced by an isentropic turbine, we would have

$$s_{4s} = s_3 = s_f @ 0.7 \text{ MPa} = 0.33230 \text{ kJ/kg}\cdot\text{K}$$

and the enthalpy at the turbine exit would be

$$x_{4s} = \left(\frac{s_{4s} - s_f}{s_{fg}} \right) @ 120 \text{ kPa} = \frac{0.33230 - 0.09275}{0.85503} = 0.2802$$

$$h_{4s} = (h_f + x_{4s} h_{fg}) @ 120 \text{ kPa} = 22.49 + (0.2802)(214.48) = 82.58 \text{ kJ/kg}$$

Then,

$$\dot{Q}_L = \dot{m}(h_1 - h_{4s}) = (0.05 \text{ kg/s})(236.97 - 82.58) \text{ kJ/kg} = 7.72 \text{ kW}$$

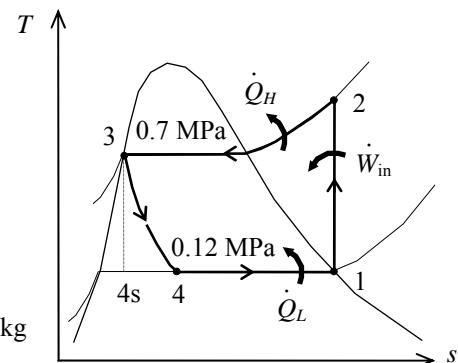

and

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{7.72 \text{ kW}}{1.83 \text{ kW}} = 4.23$$

Then the percentage increase in \dot{Q} and COP becomes

$$\text{Increase in } \dot{Q}_L = \frac{\Delta \dot{Q}_L}{\dot{Q}_L} = \frac{7.72 - 7.41}{7.41} = 4.2\%$$

$$\text{Increase in } \text{COP}_R = \frac{\Delta \text{COP}_R}{\text{COP}_R} = \frac{4.23 - 4.06}{4.06} = 4.2\%$$

11-17 A refrigerator with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the isentropic efficiency of the compressor, and the COP of the refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant tables (Tables A-12 and A-13),

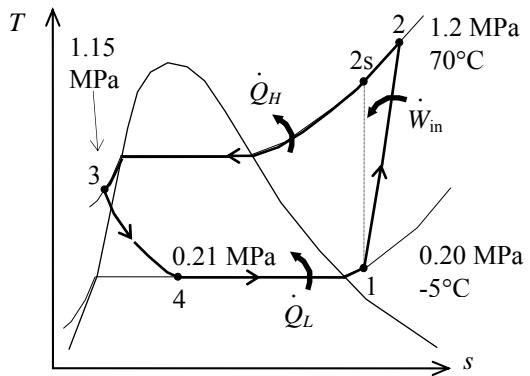

$$\begin{aligned} P_1 &= 0.20 \text{ MPa} & h_1 &= 248.80 \text{ kJ/kg} \\ T_1 &= -5^\circ\text{C} & s_1 &= 0.95407 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} P_2 &= 1.2 \text{ MPa} & h_2 &= 300.61 \text{ kJ/kg} \\ T_2 &= 70^\circ\text{C} & s_2 &= s_1 \end{aligned}$$

$$\begin{aligned} P_{2s} &= 1.2 \text{ MPa} & h_{2s} &= 287.21 \text{ kJ/kg} \\ s_{2s} &= s_1 & & \end{aligned}$$

$$\begin{aligned} P_3 &= 1.15 \text{ MPa} & h_3 &= h_f @ 44^\circ\text{C} = 114.28 \text{ kJ/kg} \\ T_3 &= 44^\circ\text{C} & s_3 &= s_1 \end{aligned}$$

$$h_4 \cong h_3 = 114.28 \text{ kJ/kg} \text{ (throttling)}$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.07 \text{ kg/s})(248.80 - 114.28) \text{ kJ/kg} = \mathbf{9.42 \text{ kW}}$$

and

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.07 \text{ kg/s})(300.61 - 248.80) \text{ kJ/kg} = \mathbf{3.63 \text{ kW}}$$

(b) The isentropic efficiency of the compressor is determined from

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{287.21 - 248.80}{300.61 - 248.80} = 0.741 = \mathbf{74.1\%}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{9.42 \text{ kW}}{3.63 \text{ kW}} = \mathbf{2.60}$$

11-18E An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The mass flow rate of the refrigerant and the power requirement are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} T_1 = 5^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 50^\circ\text{F} = 103.82 \text{ Btu/lbm} \\ s_1 = s_g @ 5^\circ\text{F} = 0.22485 \text{ Btu/lbm} \cdot \text{R} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = 180 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 121.99 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 180 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 180 \text{ psia} = 51.50 \text{ Btu/lbm}$$

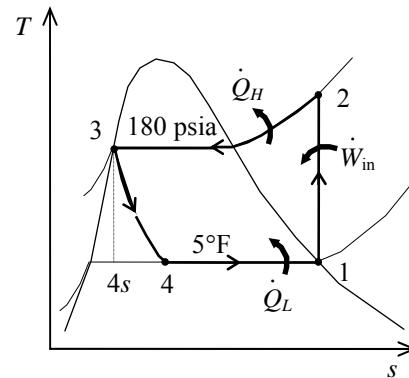

$$h_4 \cong h_3 = 51.50 \text{ Btu/lbm} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{45,000 \text{ Btu/h}}{(103.82 - 51.50) \text{ Btu/lbm}} = \mathbf{860.1 \text{ lbm/h}}$$

The power requirement is

$$\dot{W}_{in} = \dot{m}(h_2 - h_1) = (860.1 \text{ lbm/h})(121.99 - 103.82) \text{ Btu/lbm} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{4.582 \text{ kW}}$$

11-19E Problem 11-18E is to be repeated if ammonia is used as the refrigerant.

Analysis The problem is solved using EES, and the solution is given below.

11-20 A commercial refrigerator with refrigerant-134a as the working fluid is considered. The quality of the refrigerant at the evaporator inlet, the refrigeration load, the COP of the refrigerator, and the theoretical maximum refrigeration load for the same power input to the compressor are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} P_1 &= 60 \text{ kPa} \\ T_1 &= -34^\circ\text{C} \quad h_1 = 230.03 \text{ kJ/kg} \\ P_2 &= 1200 \text{ kPa} \\ T_2 &= 65^\circ\text{C} \quad h_2 = 295.16 \text{ kJ/kg} \\ P_3 &= 1200 \text{ kPa} \\ T_3 &= 42^\circ\text{C} \quad h_3 = 111.23 \text{ kJ/kg} \\ h_4 &= h_3 = 111.23 \text{ kJ/kg} \\ P_4 &= 60 \text{ kPa} \\ h_4 &= 111.23 \text{ kJ/kg} \quad x_4 = \mathbf{0.4795} \end{aligned}$$

Using saturated liquid enthalpy at the given temperature, for water we have (Table A-4)

$$h_{w1} = h_f @ 18^\circ\text{C} = 75.47 \text{ kJ/kg}$$

$$h_{w2} = h_f @ 26^\circ\text{C} = 108.94 \text{ kJ/kg}$$

(b) The mass flow rate of the refrigerant may be determined from an energy balance on the compressor

$$\begin{aligned} \dot{m}_R(h_2 - h_3) &= \dot{m}_w(h_{w2} - h_{w1}) \\ \dot{m}_R(295.16 - 111.23) \text{ kJ/kg} &= (0.25 \text{ kg/s})(108.94 - 75.47) \text{ kJ/kg} \\ \longrightarrow \dot{m}_R &= 0.0455 \text{ kg/s} \end{aligned}$$

The waste heat transferred from the refrigerant, the compressor power input, and the refrigeration load are

$$\dot{Q}_H = \dot{m}_R(h_2 - h_3) = (0.0455 \text{ kg/s})(295.16 - 111.23) \text{ kJ/kg} = 8.367 \text{ kW}$$

$$\dot{W}_{in} = \dot{m}_R(h_2 - h_1) - \dot{Q}_{in} = (0.0455 \text{ kg/s})(295.16 - 230.03) \text{ kJ/kg} - 0.450 \text{ kW} = 2.513 \text{ kW}$$

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{in} - \dot{Q}_{in} = 8.367 - 2.513 - 0.450 = \mathbf{5.404 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition

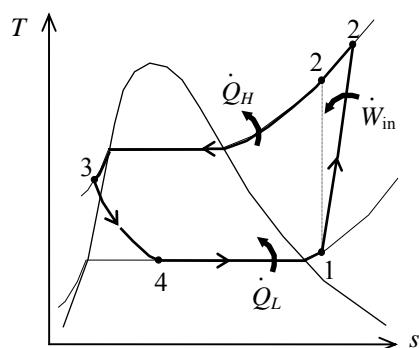

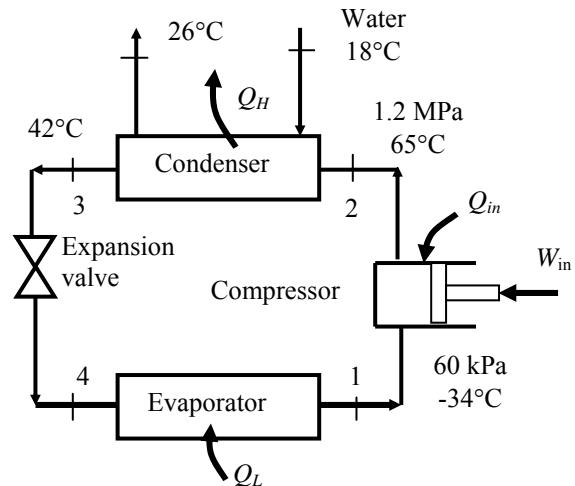

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{5.404}{2.513} = \mathbf{2.15}$$

(d) The reversible COP of the refrigerator for the same temperature limits is

$$\text{COP}_{max} = \frac{1}{T_H/T_L - 1} = \frac{1}{(18 + 273)/(-30 + 273) - 1} = 5.063$$

Then, the maximum refrigeration load becomes

$$\dot{Q}_{L,max} = \text{COP}_{max} \dot{W}_{in} = (5.063)(2.513 \text{ kW}) = \mathbf{12.72 \text{ kW}}$$

11-21 A refrigerator with refrigerant-134a as the working fluid is considered. The power input to the compressor, the rate of heat removal from the refrigerated space, and the pressure drop and the rate of heat gain in the line between the evaporator and the compressor are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant tables (Tables A-12 and A-13),

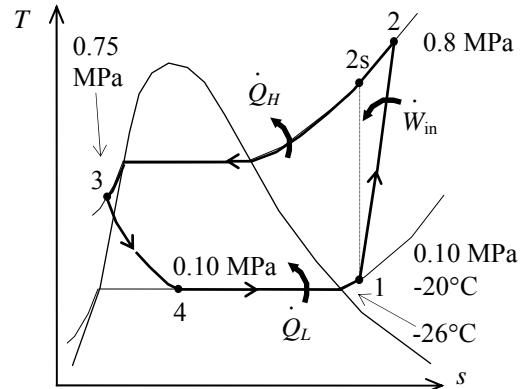

$$\begin{aligned} P_1 &= 100 \text{ kPa} & h_1 &= 239.50 \text{ kJ/kg} \\ T_1 &= -20^\circ\text{C} & s_1 &= 0.97207 \text{ kJ/kg} \cdot \text{K} \\ v_1 &= 0.19841 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} P_2 &= 0.8 \text{ MPa} & h_{2s} &= 284.07 \text{ kJ/kg} \\ s_{2s} &= s_1 \end{aligned}$$

$$\begin{aligned} P_3 &= 0.75 \text{ MPa} & h_3 &\equiv h_f @ 26^\circ\text{C} = 87.83 \text{ kJ/kg} \\ T_3 &= 26^\circ\text{C} \end{aligned}$$

$$h_4 \cong h_3 = 87.83 \text{ kJ/kg} \text{ (throttling)}$$

$$\begin{aligned} T_5 &= -26^\circ\text{C} & P_5 &= 0.10173 \text{ MPa} \\ \text{sat. vapor} & & h_5 &= 234.68 \text{ kJ/kg} \end{aligned}$$

Then the mass flow rate of the refrigerant and the power input becomes

$$\dot{m} = \frac{\dot{V}_1}{v_1} = \frac{0.5/60 \text{ m}^3/\text{s}}{0.19841 \text{ m}^3/\text{kg}} = 0.0420 \text{ kg/s}$$

$$\dot{W}_{in} = \dot{m}(h_{2s} - h_1)/\eta_C = (0.0420 \text{ kg/s})(284.07 - 239.50) \text{ kJ/kg}/(0.78) = \mathbf{2.40 \text{ kW}}$$

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}(h_5 - h_4) = (0.0420 \text{ kg/s})(234.68 - 87.83) \text{ kJ/kg} = \mathbf{6.17 \text{ kW}}$$

(c) The pressure drop and the heat gain in the line between the evaporator and the compressor are

$$\Delta P = P_5 - P_1 = 101.73 - 100 = \mathbf{1.73}$$

and

$$\dot{Q}_{gain} = \dot{m}(h_1 - h_5) = (0.0420 \text{ kg/s})(239.50 - 234.68) \text{ kJ/kg} = \mathbf{0.203 \text{ kW}}$$

11-22 Problem 11-21 is reconsidered. The effects of the compressor isentropic efficiency and the compressor inlet volume flow rate on the power input and the rate of refrigeration are to be investigated.

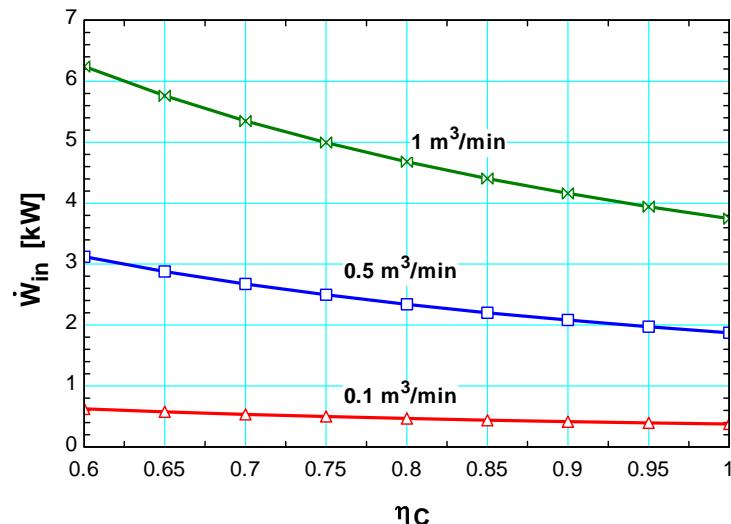

Analysis The problem is solved using EES, and the solution is given below.

11-23 A refrigerator uses refrigerant-134a as the working fluid and operates on the ideal vapor-compression refrigeration cycle except for the compression process. The mass flow rate of the refrigerant, the condenser pressure, and the COP of the refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) (b) From the refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} P_4 &= 120 \text{ kPa} \\ x_4 &= 0.30 \quad \left. \begin{aligned} h_4 &= 86.83 \text{ kJ/kg} \\ h_3 &= h_4 \end{aligned} \right\} \\ h_3 &= 86.83 \text{ kJ/kg} \\ x_3 &= 0 \text{ (sat. liq.)} \quad \left. \begin{aligned} P_3 &= 671.8 \text{ kPa} \\ P_2 &= P_3 \end{aligned} \right\} \\ P_2 &= 671.8 \text{ kPa} \\ T_2 &= 60^\circ\text{C} \quad \left. \begin{aligned} h_2 &= 298.87 \text{ kJ/kg} \\ P_1 &= P_4 = 120 \text{ kPa} \end{aligned} \right\} \\ x_1 &= 1 \text{ (sat. vap.)} \quad \left. \begin{aligned} h_1 &= 236.97 \text{ kJ/kg} \\ x=0.3 & \end{aligned} \right\} \end{aligned}$$

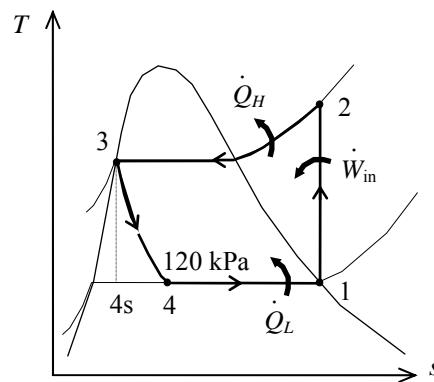

The mass flow rate of the refrigerant is determined from

$$\dot{m} = \frac{\dot{W}_{in}}{h_2 - h_1} = \frac{0.45 \text{ kW}}{(298.87 - 236.97) \text{ kJ/kg}} = \mathbf{0.00727 \text{ kg/s}}$$

(c) The refrigeration load and the COP are

$$\begin{aligned} \dot{Q}_L &= \dot{m}(h_1 - h_4) \\ &= (0.0727 \text{ kg/s})(236.97 - 86.83) \text{ kJ/kg} \\ &= 1.091 \text{ kW} \end{aligned}$$

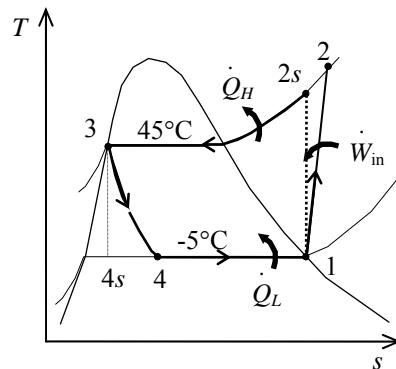

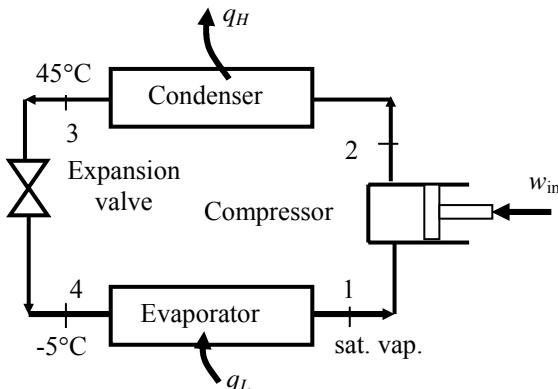

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{1.091 \text{ kW}}{0.45 \text{ kW}} = \mathbf{2.43}$$

11-24 A vapor-compression refrigeration cycle with refrigerant-22 as the working fluid is considered. The hardware and the $T-s$ diagram for this air conditioner are to be sketched. The heat absorbed by the refrigerant, the work input to the compressor and the heat rejected in the condenser are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In this normal vapor-compression refrigeration cycle, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

(b) The properties as given in the problem statement are

$$h_4 = h_3 = h_f @ 45^\circ\text{C} = 101 \text{ kJ/kg}$$

$$h_1 = h_g @ -5^\circ\text{C} = 248.1 \text{ kJ/kg}.$$

The heat absorbed by the refrigerant in the evaporator is

$$q_L = h_1 - h_4 = 248.1 - 101 = \mathbf{147.1 \text{ kJ/kg}}$$

(c) The COP of the air conditioner is

$$\text{COP}_R = \text{SEER} \left(\frac{1 \text{ W}}{3.412 \text{ Btu/h}} \right) = \left(16 \frac{\text{Btu/h}}{\text{W}} \right) \left(\frac{1 \text{ W}}{3.412 \text{ Btu/h}} \right) = 4.689$$

The work input to the compressor is

$$\text{COP}_R = \frac{q_L}{w_{in}} \longrightarrow w_{in} = \frac{q_L}{\text{COP}_R} = \frac{147.1 \text{ kJ/kg}}{4.689} = \mathbf{31.4 \text{ kJ/kg}}$$

The enthalpy at the compressor exit is

$$w_{in} = h_2 - h_1 \longrightarrow h_2 = h_1 + w_{in} = 248.1 \text{ kJ/kg} + 31.4 \text{ kJ/kg} = 279.5 \text{ kJ/kg}$$

The heat rejected from the refrigerant in the condenser is then

$$q_H = h_2 - h_3 = 279.5 - 101 = \mathbf{178.5 \text{ kJ/kg}}$$

11-25 A vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The amount of cooling, the work input, and the COP are to be determined. Also, the same parameters are to be determined if the cycle operated on the ideal vapor-compression refrigeration cycle between the same temperature limits.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

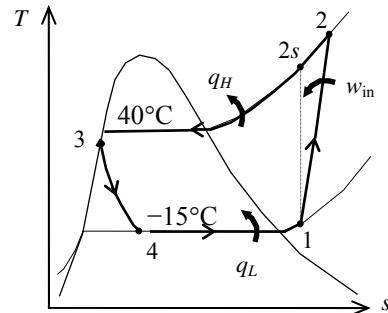

Analysis (a) The expansion process through the expansion valve is isenthalpic: $h_4 = h_3$. Then,

$$q_L = h_1 - h_4 = 402.49 - 243.19 = \mathbf{159.3 \text{ kJ/kg}}$$

$$q_H = h_2 - h_3 = 454.00 - 243.19 = 210.8 \text{ kJ/kg}$$

$$w_{\text{in}} = h_2 - h_1 = 454.00 - 402.49 = \mathbf{51.51 \text{ kJ/kg}}$$

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{159.3 \text{ kJ/kg}}{51.51 \text{ kJ/kg}} = \mathbf{3.093}$$

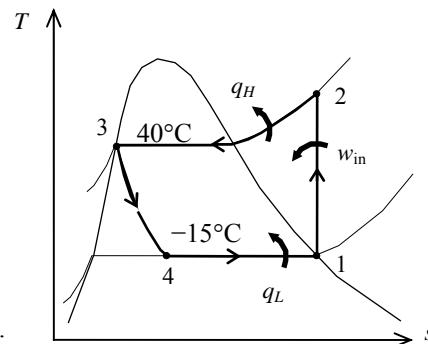

(c) Ideal vapor-compression refrigeration cycle solution:

$$q_L = h_1 - h_4 = 399.04 - 249.80 = \mathbf{149.2 \text{ kJ/kg}}$$

$$q_H = h_2 - h_3 = 440.71 - 249.80 = 190.9 \text{ kJ/kg}$$

$$w_{\text{in}} = h_2 - h_1 = 440.71 - 399.04 = \mathbf{41.67 \text{ kJ/kg}}$$

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{149.2 \text{ kJ/kg}}{41.67 \text{ kJ/kg}} = \mathbf{3.582}$$

Discussion In the ideal operation, the refrigeration load decreases by 6.3% and the work input by 19.1% while the COP increases by 15.8%.

11-26 A vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The rate of cooling, the power input, and the COP are to be determined. Also, the same parameters are to be determined if the cycle operated on the ideal vapor-compression refrigeration cycle between the same pressure limits.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant-134a tables (Tables A-11 through A-13)

$$T_{\text{sat}@200 \text{ kPa}} = -10.1^\circ\text{C}$$

$$\begin{aligned} P_1 &= 200 \text{ kPa} & h_1 &= 253.05 \text{ kJ/kg} \\ T_1 &= -10.1 + 10.1 = 0^\circ\text{C} & s_1 &= 0.9698 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} P_2 &= 1400 \text{ kPa} & h_{2s} &= 295.90 \text{ kJ/kg} \\ s_1 &= s_1 & s_1 &= s_1 \end{aligned}$$

$$T_{\text{sat}@1400 \text{ kPa}} = 52.4^\circ\text{C}$$

$$\begin{aligned} P_3 &= 1400 \text{ kPa} & h_3 &\equiv h_{f@48^\circ\text{C}} = 120.39 \text{ kJ/kg} \\ T_3 &= 52.4 - 4.4 = 48^\circ\text{C} & s_3 &= 0.9377 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$h_4 = h_3 = 120.39 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

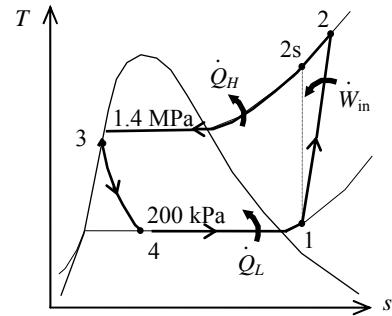

$$0.88 = \frac{295.90 - 253.05}{h_2 - 253.05} \rightarrow h_2 = 301.74 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.025 \text{ kg/s})(253.05 - 120.39) = \mathbf{3.317 \text{ kW}}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.025 \text{ kg/s})(301.74 - 120.39) = \mathbf{4.534 \text{ kW}}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.025 \text{ kg/s})(301.74 - 253.05) = \mathbf{1.217 \text{ kW}}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{3.317 \text{ kW}}{1.217 \text{ kW}} = \mathbf{2.725}$$

(b) Ideal vapor-compression refrigeration cycle solution

From the refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} P_1 &= 200 \text{ kPa} & h_1 &= 244.46 \text{ kJ/kg} \\ x_1 &= 1 & s_1 &= 0.9377 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} P_2 &= 1400 \text{ kPa} & h_2 &= 285.08 \text{ kJ/kg} \\ s_1 &= s_1 & s_1 &= s_1 \end{aligned}$$

$$\begin{aligned} P_3 &= 1400 \text{ kPa} & h_3 &= 127.22 \text{ kJ/kg} \\ x_3 &= 0 & x_3 &= 0 \end{aligned}$$

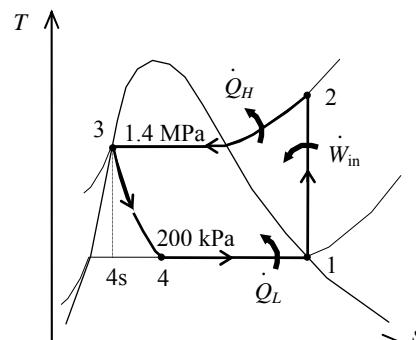

$$h_4 = h_3 = 127.22 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.025 \text{ kg/s})(244.46 - 127.22) = \mathbf{3.931 \text{ kW}}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.025 \text{ kg/s})(285.08 - 127.22) = \mathbf{3.947 \text{ kW}}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.025 \text{ kg/s})(285.08 - 244.46) = \mathbf{1.016 \text{ kW}}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{3.931 \text{ kW}}{1.016 \text{ kW}} = \mathbf{2.886}$$

Discussion The cooling load increases by 18.5% while the COP increases by 5.9% when the cycle operates on the ideal vapor-compression cycle.

Second-Law Analysis of Vapor-Compression Refrigeration Cycles

11-27C The second-law efficiency of a refrigerator operating on the vapor-compression refrigeration cycle is defined as

$$\eta_{II,R} = \frac{\dot{X}_{\dot{Q}_L}}{\dot{W}} = \frac{\dot{W}_{min}}{\dot{W}} = 1 - \frac{\dot{X}_{dest,total}}{\dot{W}}$$

where $\dot{X}_{\dot{Q}_L}$ is the exergy of the heat transferred from the low-temperature medium and it is expressed as

$$\dot{X}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right).$$

$\dot{X}_{dest,total}$ is the total exergy destruction in the cycle and \dot{W} is the actual power input to the cycle. The second-law efficiency can also be expressed as the ratio of the actual COP to the Carnot COP:

$$\eta_{II,R} = \frac{COP_R}{COP_{Carnot}}$$

11-28C The second-law efficiency of a heat pump operating on the a vapor-compression refrigeration cycle is defined as

$$\eta_{II,HP} = \frac{\dot{Ex}_{\dot{Q}_H}}{\dot{W}} = \frac{\dot{W}_{min}}{\dot{W}} = 1 - \frac{\dot{Ex}_{dest,total}}{\dot{W}}$$

Substituting

$$\dot{W} = \frac{\dot{Q}_H}{COP_{HP}} \quad \text{and} \quad \dot{Ex}_{\dot{Q}_H} = \dot{Q}_H \left(1 - \frac{T_0}{T_H} \right)$$

into the second-law efficiency equation

$$\eta_{II,HP} = \frac{\dot{Ex}_{\dot{Q}_H}}{\dot{W}} = \frac{\dot{Q}_H \left(1 - \frac{T_0}{T_H} \right)}{\frac{\dot{Q}_H}{COP_{HP}}} = \dot{Q}_H \left(1 - \frac{T_0}{T_H} \right) \frac{COP_{HP}}{\dot{Q}_H} = \frac{COP_{HP}}{\frac{T_H}{T_H - T_L}} = \frac{COP_{HP}}{COP_{Carnot}}$$

since $T_0 = T_L$.

11-29C In an isentropic compressor, $s_2 = s_1$ and $h_{2s} = h_2$. Applying these to the two efficiency definitions, we obtain

$$\eta_{s, \text{Comp}} = \frac{w_{\text{isen}}}{w} = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{h_2 - h_1}{h_2 - h_1} = 1 = 100\%$$

$$\eta_{II, \text{Comp}} = \frac{w_{\text{rev}}}{w} = \frac{h_2 - h_1 - T_0(s_2 - s_1)}{h_2 - h_1} = \frac{h_2 - h_1}{h_2 - h_1} = 1 = 100\%$$

Thus, the isentropic efficiency and the exergy efficiency of an isentropic compressor are both 100%.

The exergy efficiency of a compressor is not necessarily equal to its isentropic efficiency. The two definitions are different as shown in the above equations. In the calculation of isentropic efficiency, the exit enthalpy is found at the hypothetical exit state (at the exit pressure and the inlet entropy) while the exergy efficiency involves the actual exit state. The two efficiencies are usually close but different. In the special case of an isentropic compressor, the two efficiencies become equal to each other as proven above.

11-30 A vapor-compression refrigeration system is used to keep a space at a low temperature. The power input, the COP and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The power input is

$$\dot{W}_{\text{in}} = \dot{Q}_H - \dot{Q}_L = 6000 - 3500 = 2500 \text{ kJ/h} = (2500 \text{ kJ/h}) \left(\frac{1 \text{ kW}}{3600 \text{ kJ/h}} \right) = \mathbf{0.6944 \text{ kW}}$$

The COP is

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(3500 / 3600) \text{ kW}}{0.6944 \text{ kW}} = \mathbf{1.4}$$

The COP of the Carnot cycle operating between the space and the ambient is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{250 \text{ K}}{(298 - 250) \text{ K}} = 5.208$$

The second-law efficiency is then

$$\eta_{II} = \frac{\text{COP}_R}{\text{COP}_{\text{Carnot}}} = \frac{1.4}{5.208} = 0.2688 = \mathbf{26.9\%}$$

11-31 A refrigerator is used to cool bananas at a specified rate. The rate of heat absorbed from the bananas, the COP, The minimum power input, the second-law efficiency and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The rate of heat absorbed from the bananas is

$$\dot{Q}_L = \dot{m}c_p(T_1 - T_2) = (1140 \text{ kg/h})(3.35 \text{ kJ/kg} \cdot ^\circ\text{C})(28 - 12)^\circ\text{C} = \mathbf{61,100 \text{ kJ/h}}$$

The COP is

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(61,100 / 3600) \text{ kW}}{8.6 \text{ kW}} = \frac{16.97 \text{ kW}}{8.6 \text{ kW}} = \mathbf{1.97}$$

(b) The minimum power input is equal to the exergy of the heat transferred from the low-temperature medium:

$$\dot{Ex}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L}\right) = -(16.97 \text{ kW}) \left(1 - \frac{28 + 273}{20 + 273}\right) = \mathbf{0.463 \text{ kW}}$$

where the dead state temperature is taken as the inlet temperature of the eggplants ($T_0 = 28^\circ\text{C}$) and the temperature of the low-temperature medium is taken as the average temperature of bananas $T = (12+28)/2 = 20^\circ\text{C}$.

(c) The second-law efficiency of the cycle is

$$\eta_{II} = \frac{\dot{Ex}_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{0.463}{8.6} = 0.0539 = \mathbf{5.39\%}$$

The exergy destruction is the difference between the exergy expended (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{Ex}_{\text{dest}} = \dot{W}_{\text{in}} - \dot{Ex}_{\dot{Q}_L} = 8.6 - 0.463 = \mathbf{8.14 \text{ kW}}$$

11-32 A vapor-compression refrigeration cycle is used to keep a space at a low temperature. The power input, the mass flow rate of water in the condenser, the second-law efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The power input is

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}} = \frac{(24,000 \text{ Btu/h}) \left(\frac{1 \text{ kW}}{3412 \text{ Btu/h}} \right)}{2.05} = \frac{7.034 \text{ kW}}{2.05} = \mathbf{3.431 \text{ kW}}$$

(b) From an energy balance on the cycle,

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{\text{in}} = 7.034 + 3.431 = 10.46 \text{ kW}$$

The mass flow rate of the water is then determined from

$$\dot{Q}_H = \dot{m} c_{pw} \Delta T_w \longrightarrow \dot{m} = \frac{\dot{Q}_H}{c_{pw} \Delta T_w} = \frac{10.46 \text{ kW}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(12^\circ\text{C})} = \mathbf{0.2086 \text{ kg/s}}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$\dot{Ex}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(7.034 \text{ kW}) \left(1 - \frac{20 + 273}{0 + 273} \right) = 0.5153 \text{ kW}$$

The second-law efficiency of the cycle is

$$\eta_{II} = \frac{\dot{Ex}_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{0.5153}{3.431} = 0.1502 = \mathbf{15.0\%}$$

The exergy destruction is the difference between the exergy supplied (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{Ex}_{\text{dest}} = \dot{W}_{\text{in}} - \dot{Ex}_{\dot{Q}_L} = 3.431 - 0.5153 = \mathbf{2.916 \text{ kW}}$$

Alternative Solution

The exergy efficiency can also be determined as follows:

$$\text{COP}_{R,\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{0 + 273}{20 - 0} = 13.65$$

$$\eta_{II} = \frac{\text{COP}}{\text{COP}_{R,\text{Carnot}}} = \frac{2.05}{13.65} = 0.1502 = 15.0\%$$

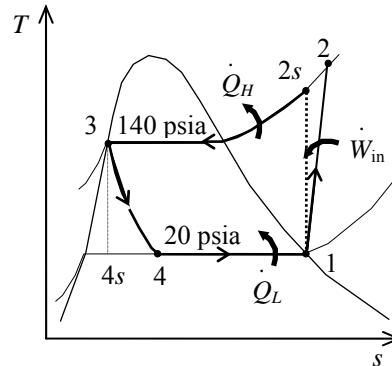

The result is identical as expected.

11-33E A vapor-compression refrigeration cycle is used to keep a space at a low temperature. The mass flow rate of R-134a, the COP, The exergy destruction in each component and the exergy efficiency of the compressor, the second-law efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11E through A-13E)

$$\begin{aligned} P_1 &= 20 \text{ psia} & h_1 &= 102.73 \text{ Btu/lbm} \\ x_1 &= 1 & s_1 &= 0.2257 \text{ Btu/lbm} \cdot \text{R} \\ P_2 &= 140 \text{ psia} & h_2 &= 131.36 \text{ Btu/lbm} \\ T_2 &= 160^\circ\text{F} & s_2 &= 0.2444 \text{ Btu/lbm} \cdot \text{R} \\ P_3 &= 140 \text{ psia} & h_3 &= 45.30 \text{ Btu/lbm} \\ x_3 &= 0 & s_3 &= 0.0921 \text{ Btu/lbm} \cdot \text{R} \\ h_4 &= h_3 = 45.30 \text{ Btu/lbm} \\ P_4 &= 20 \text{ psia} & s_4 &= 0.1001 \text{ Btu/lbm} \cdot \text{R} \\ h_4 &= 45.30 \text{ Btu/lbm} \end{aligned}$$

The energy interactions in each component and the mass flow rate of R-134a are

$$w_{in} = h_2 - h_1 = 131.36 - 102.73 = 28.63 \text{ Btu/lbm}$$

$$q_H = h_2 - h_3 = 131.36 - 45.30 = 86.06 \text{ Btu/lbm}$$

$$q_L = q_H - w_{in} = 86.06 - 28.63 = 57.43 \text{ Btu/lbm}$$

$$\dot{m} = \frac{\dot{Q}_L}{q_L} = \frac{(45,000 / 3600) \text{ Btu/s}}{57.43 \text{ Btu/lbm}} = \mathbf{0.2177 \text{ lbm/s}}$$

The COP is

$$\text{COP} = \frac{q_L}{w_{in}} = \frac{57.43 \text{ Btu/lbm}}{28.63 \text{ Btu/lbm}} = \mathbf{2.006}$$

(b) The exergy destruction in each component of the cycle is determined as follows:

Compressor:

$$s_{gen,1-2} = s_2 - s_1 = 0.2444 - 0.2257 = 0.01874 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{Ex}_{dest,1-2} = \dot{m} T_0 s_{gen,1-2} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.01874 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{2.203 \text{ Btu/s}}$$

Condenser:

$$s_{gen,2-3} = s_3 - s_2 + \frac{q_H}{T_H} = (0.0921 - 0.2444) \text{ Btu/lbm} \cdot \text{R} + \frac{86.06 \text{ Btu/lbm}}{540 \text{ R}} = 0.007073 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{Ex}_{dest,2-3} = \dot{m} T_0 s_{gen,2-3} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.007073 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{0.8313 \text{ Btu/s}}$$

Expansion valve:

$$s_{gen,3-4} = s_4 - s_3 = 0.1001 - 0.0921 = 0.007962 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{Ex}_{dest,3-4} = \dot{m} T_0 s_{gen,3-4} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.007962 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{0.9359 \text{ Btu/s}}$$

Evaporator:

$$s_{gen,4-1} = s_1 - s_4 - \frac{q_L}{T_L} = (0.2257 - 0.1001) \text{ Btu/lbm} \cdot \text{R} - \frac{57.43 \text{ Btu/lbm}}{470 \text{ R}} = 0.003400 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{Ex}_{dest,4-1} = \dot{m} T_0 s_{gen,4-1} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.003400 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{0.3996 \text{ Btu/s}}$$

The power input and the exergy efficiency of the compressor is determined from

$$\dot{W}_{\text{in}} = \dot{m}w_{\text{in}} = (0.2177 \text{ lbm/s})(28.63 \text{ Btu/lbm}) = 6.232 \text{ Btu/s}$$

$$\eta_{\text{II}} = 1 - \frac{\dot{E}x_{\text{dest},1-2}}{\dot{W}_{\text{in}}} = 1 - \frac{2.203 \text{ Btu/s}}{6.232 \text{ Btu/s}} = 0.6465 = \mathbf{64.7\%}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$\dot{E}x_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(45000 / 3600 \text{ Btu/s}) \left(1 - \frac{540}{470} \right) = 1.862 \text{ Btu/s}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{E}x_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{1.862 \text{ Btu/s}}{6.232 \text{ Btu/s}} = 0.2987 = \mathbf{29.9\%}$$

The total exergy destruction in the cycle is the difference between the exergy supplied (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{E}x_{\text{dest,total}} = \dot{W}_{\text{in}} - \dot{E}x_{\dot{Q}_L} = 6.232 - 1.862 = \mathbf{4.370 \text{ Btu/s}}$$

The total exergy destruction can also be determined by adding exergy destructions in each component:

$$\begin{aligned} \dot{E}x_{\text{dest,total}} &= \dot{E}x_{\text{dest},1-2} + \dot{E}x_{\text{dest},2-3} + \dot{E}x_{\text{dest},3-4} + \dot{E}x_{\text{dest},4-1} \\ &= 2.203 + 0.8313 + 0.9359 + 0.3996 \\ &= 4.370 \text{ Btu/s} \end{aligned}$$

The result is the same as expected.

11-34 A vapor-compression refrigeration cycle is used to keep a space at a low temperature. The mass flow rate of R-134a, the COP, The exergy destruction in each component and the exergy efficiency of the compressor, the second-law efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11 through A-13)

$$\begin{aligned} P_2 &= 1.2 \text{ MPa} \quad h_2 = 278.27 \text{ kJ/kg} \\ T_2 &= 50^\circ\text{C} \quad s_2 = 0.9267 \text{ kJ/kg} \cdot \text{K} \\ P_3 &= 1.2 \text{ MPa} \quad h_3 = 117.77 \text{ kJ/kg} \\ x_3 &= 0 \quad s_3 = 0.4244 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The rate of heat transferred to the water is the energy change of the water from inlet to exit

$$\dot{Q}_H = \dot{m}_w c_p (T_{w,2} - T_{w,1}) = (0.15 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(28 - 20)^\circ\text{C} = 5.016 \text{ kW}$$

The energy decrease of the refrigerant is equal to the energy increase of the water in the condenser. That is,

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) \longrightarrow \dot{m}_R = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{5.016 \text{ kW}}{(278.27 - 117.77) \text{ kJ/kg}} = 0.03125 \text{ kg/s}$$

The refrigeration load is

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{in} = 5.016 - 2.2 = 2.816 \text{ kW} = (2.816 \text{ kW}) \left(\frac{3412 \text{ Btu/h}}{1 \text{ kW}} \right) = \mathbf{9610 \text{ Btu/h}}$$

The COP of the refrigerator is determined from its definition,

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{2.816 \text{ kW}}{2.2 \text{ kW}} = \mathbf{1.28}$$

(b) The COP of a reversible refrigerator operating between the same temperature limits is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{-12 + 273}{(20 + 273) - (-12 + 273)} = 8.156$$

The minimum power input to the compressor for the same refrigeration load would be

$$\dot{W}_{in,\min} = \frac{\dot{Q}_L}{\text{COP}_{\text{Carnot}}} = \frac{2.816 \text{ kW}}{8.156} = 0.3453 \text{ kW}$$

The second-law efficiency of the cycle is

$$\eta_{II} = \frac{\dot{W}_{in,\min}}{\dot{W}_{in}} = \frac{0.3453}{2.2} = 0.1569 = \mathbf{15.7\%}$$

The total exergy destruction in the cycle is the difference between the actual and the minimum power inputs:

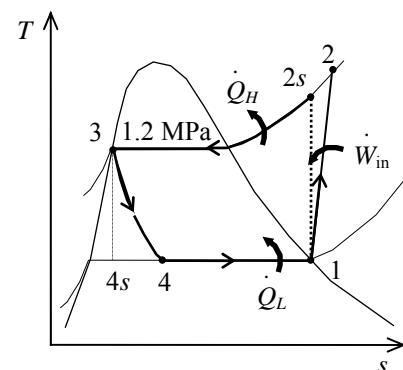

$$\dot{Ex}_{\text{dest},\text{total}} = \dot{W}_{in} - \dot{W}_{in,\min} = 2.2 - 0.3453 = \mathbf{1.85 \text{ kW}}$$

(c) The entropy generation in the condenser is

$$\begin{aligned} \dot{S}_{\text{gen,cond}} &= \dot{m}_w c_p \ln\left(\frac{T_{w,2}}{T_{w,1}}\right) + \dot{m}_R (s_3 - s_2) \\ &= (0.15 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C}) \ln\left(\frac{28 + 273}{20 + 273}\right) + (0.03125 \text{ kg/s})(0.4004 - 0.9267) \text{ kJ/kg} \cdot \text{K} \\ &= 0.001191 \text{ kW/K} \end{aligned}$$

The exergy destruction in the condenser is

$$\dot{Ex}_{\text{dest,cond}} = T_0 \dot{S}_{\text{gen,cond}} = (293 \text{ K})(0.001191 \text{ kW/K}) = \mathbf{0.349 \text{ kW}}$$

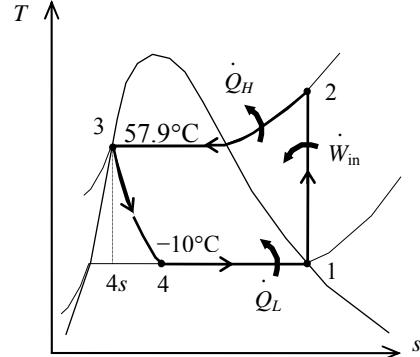

11-35 An ideal vapor-compression refrigeration cycle is used to keep a space at a low temperature. The cooling load, the COP, the exergy destruction in each component, the total exergy destruction, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11 through A-13)

$$\begin{aligned} T_1 &= -10^\circ\text{C} \quad h_1 = 244.51 \text{ kJ/kg} \\ x_1 &= 1 \quad s_1 = 0.9377 \text{ kJ/kg} \cdot \text{K} \\ P_2 &= P_{\text{sat}}@57.9^\circ\text{C} = 1600 \text{ kPa} \quad h_2 = 287.85 \text{ kJ/kg} \\ s_2 &= s_1 \\ P_3 &= 1600 \text{ kPa} \quad h_3 = 135.93 \text{ kJ/kg} \\ x_3 &= 0 \quad s_3 = 0.4791 \text{ kJ/kg} \cdot \text{K} \\ h_4 &= h_3 = 135.93 \text{ kJ/kg} \\ T_4 &= -10^\circ\text{C} \quad s_4 = 0.5251 \text{ kJ/kg} \cdot \text{K} \\ h_4 &= 135.93 \text{ kJ/kg} \end{aligned}$$

The energy interactions in the components and the COP are

$$q_L = h_1 - h_4 = 244.51 - 135.93 = \mathbf{108.6 \text{ kJ/kg}}$$

$$q_H = h_2 - h_3 = 287.85 - 135.93 = 151.9 \text{ kJ/kg}$$

$$w_{\text{in}} = h_2 - h_1 = 287.85 - 244.51 = 43.33 \text{ kJ/kg}$$

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{108.6 \text{ kJ/kg}}{43.33 \text{ kJ/kg}} = \mathbf{2.506}$$

(b) The exergy destruction in each component of the cycle is determined as follows

Compressor:

$$s_{\text{gen},1-2} = s_2 - s_1 = 0$$

$$Ex_{\text{dest},1-2} = T_0 s_{\text{gen},1-2} = 0$$

Condenser:

$$s_{\text{gen},2-3} = s_3 - s_2 + \frac{q_H}{T_H} = (0.4791 - 0.9377) \text{ kJ/kg} \cdot \text{K} + \frac{151.9 \text{ kJ/kg}}{298 \text{ K}} = 0.05124 \text{ kJ/kg} \cdot \text{K}$$

$$Ex_{\text{dest},2-3} = T_0 s_{\text{gen},2-3} = (298 \text{ K})(0.05124 \text{ kJ/kg} \cdot \text{K}) = \mathbf{15.27 \text{ kJ/kg}}$$

Expansion valve:

$$s_{\text{gen},3-4} = s_4 - s_3 = 0.5251 - 0.4791 = 0.04595 \text{ kJ/kg} \cdot \text{K}$$

$$Ex_{\text{dest},3-4} = T_0 s_{\text{gen},3-4} = (298 \text{ K})(0.04595 \text{ kJ/kg} \cdot \text{K}) = \mathbf{13.69 \text{ kJ/kg}}$$

Evaporator:

$$s_{\text{gen},4-1} = s_1 - s_4 - \frac{q_L}{T_L} = (0.9377 - 0.5251) \text{ kJ/kg} \cdot \text{K} - \frac{108.6 \text{ kJ/kg}}{278 \text{ K}} = 0.02201 \text{ kJ/kg} \cdot \text{K}$$

$$Ex_{\text{dest},4-1} = T_0 s_{\text{gen},4-1} = (298 \text{ K})(0.02201 \text{ kJ/kg} \cdot \text{K}) = \mathbf{6.56 \text{ kJ/kg}}$$

The total exergy destruction can be determined by adding exergy destructions in each component:

$$\begin{aligned} \dot{Ex}_{\text{dest},\text{total}} &= \dot{Ex}_{\text{dest},1-2} + \dot{Ex}_{\text{dest},2-3} + \dot{Ex}_{\text{dest},3-4} + \dot{Ex}_{\text{dest},4-1} \\ &= 0 + 15.27 + 13.69 + 6.56 = \mathbf{35.52 \text{ kJ/kg}} \end{aligned}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$Ex_{q_L} = -q_L \left(1 - \frac{T_0}{T_L}\right) = -(108.6 \text{ kJ/kg}) \left(1 - \frac{298}{278}\right) = 7.812 \text{ kJ/kg}$$

The second-law efficiency of the cycle is

$$\eta_{II} = \frac{Ex_{q_L}}{w_{in}} = \frac{7.812}{43.33} = 0.1803 = \mathbf{18.0\%}$$

The total exergy destruction in the cycle can also be determined from

$$Ex_{dest,total} = w_{in} - Ex_{q_L} = 43.33 - 7.812 = 35.52 \text{ kJ/kg}$$

The result is identical as expected.

The second-law efficiency of the compressor is determined from

$$\eta_{II,Comp} = \frac{\dot{X}_{recovered}}{\dot{X}_{expended}} = \frac{\dot{W}_{rev}}{\dot{W}_{act,in}} = \frac{\dot{m}[h_2 - h_1 - T_0(s_2 - s_1)]}{\dot{m}(h_2 - h_1)}$$

since the compression through the compressor is isentropic ($s_2 = s_1$), the second-law efficiency is

$$\eta_{II,Comp} = 1 = \mathbf{100\%}$$

The second-law efficiency of the evaporator is determined from

$$\eta_{II,Evap} = \frac{\dot{X}_{recovered}}{\dot{X}_{expended}} = \frac{\dot{Q}_L(T_0 - T_L)/T_L}{\dot{m}[h_4 - h_1 - T_0(s_4 - s_1)]} = 1 - \frac{\dot{X}_{dest,4-1}}{\dot{X}_4 - \dot{X}_1}$$

where

$$\begin{aligned} x_4 - x_1 &= h_4 - h_1 - T_0(s_4 - s_1) \\ &= (135.93 - 244.51) \text{ kJ/kg} - (298 \text{ K})(0.5251 - 0.9377) \text{ kJ/kg} \cdot \text{K} \\ &= 14.37 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$\eta_{II,Evap} = 1 - \frac{x_{dest,4-1}}{x_4 - x_1} = 1 - \frac{6.56 \text{ kJ/kg}}{14.37 \text{ kJ/kg}} = 0.544 = \mathbf{54.4\%}$$

11-36 An ideal vapor-compression refrigeration cycle uses ammonia as the refrigerant. The volume flow rate at the compressor inlet, the power input, the COP, the second-law efficiency and the total exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) The properties of ammonia are given in problem statement. An energy balance on the condenser gives

$$q_H = h_1 - h_4 = 1439.3 - 437.4 = 1361 \text{ kJ/kg}$$

$$\dot{m} = \frac{\dot{Q}_H}{q_H} = \frac{18 \text{ kW}}{1361 \text{ kJ/kg}} = 0.01323 \text{ kg/s}$$

The volume flow rate is determined from

$$\begin{aligned}\dot{V}_1 &= \dot{m}v_1 = (0.01323 \text{ kg/s})(0.5946 \text{ m}^3/\text{kg}) \\ &= 0.007865 \text{ m}^3/\text{s} = \mathbf{7.87 \text{ L/s}}\end{aligned}$$

(b) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.01323 \text{ kg/s})(1798.3 - 1439.3) \text{ kJ/kg} = \mathbf{4.75 \text{ kW}}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.01323 \text{ kg/s})(1439.3 - 437.4) \text{ kJ/kg} = 13.25 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{13.25 \text{ kW}}{4.75 \text{ kW}} = \mathbf{2.79}$$

(c) The exergy of the heat transferred from the low-temperature medium is

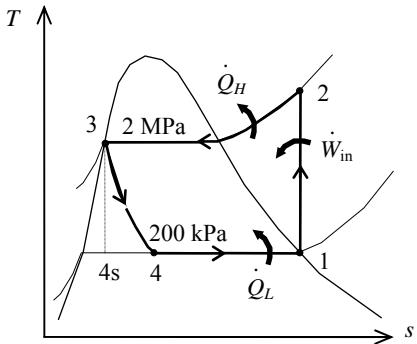

$$\dot{Ex}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(13.25 \text{ kW}) \left(1 - \frac{300}{264} \right) = 1.81 \text{ kW}$$

The second-law efficiency of the cycle is

$$\eta_{II} = \frac{\dot{Ex}_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{1.81}{4.75} = 0.381 = \mathbf{38.1\%}$$

The total exergy destruction in the cycle is the difference between the exergy supplied (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{Ex}_{\text{dest,total}} = \dot{W}_{\text{in}} - \dot{Ex}_{\dot{Q}_L} = 4.75 - 1.81 = \mathbf{2.94 \text{ kW}}$$

11-37 Prob. 11-36 is reconsidered. Using EES software, the problem is to be repeated ammonia, R-134a and R-22 is used as a refrigerant and the effects of evaporator and condenser pressures on the COP, the second-law efficiency and the total exergy destruction are to be investigated.

Analysis The equations as written in EES are

No unit problems were detected.

Calculation time = .0 sec

Now, we investigate the effects of evaporating and condenser pressures on the COP, the second-law efficiency and the total exergy destruction. The results are given by tables and figures.

Selecting the Right Refrigerant

11-38C The desirable characteristics of a refrigerant are to have an evaporator pressure which is above the atmospheric pressure, and a condenser pressure which corresponds to a saturation temperature above the temperature of the cooling medium. Other desirable characteristics of a refrigerant include being nontoxic, noncorrosive, nonflammable, chemically stable, having a high enthalpy of vaporization (minimizes the mass flow rate) and, of course, being available at low cost.

11-39C The minimum pressure that the refrigerant needs to be compressed to is the saturation pressure of the refrigerant at 30°C, which is **0.771 MPa**. At lower pressures, the refrigerant will have to condense at temperatures lower than the temperature of the surroundings, which cannot happen.

11-40C Allowing a temperature difference of 10°C for effective heat transfer, the evaporation temperature of the refrigerant should be -20°C. The saturation pressure corresponding to -20°C is 0.133 MPa. Therefore, the recommended pressure would be 0.12 MPa.

11-41 A refrigerator that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. Reasonable pressures for the evaporator and the condenser are to be selected.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis Allowing a temperature difference of 10°C for effective heat transfer, the evaporation and condensation temperatures of the refrigerant should be -20°C and 35°C, respectively. The saturation pressures corresponding to these temperatures are 0.133 MPa and 0.888 MPa. Therefore, the recommended evaporator and condenser pressures are **0.133 MPa** and **0.888 MPa**, respectively.

11-42 A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. Reasonable pressures for the evaporator and the condenser are to be selected.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis Allowing a temperature difference of 10°C for effective heat transfer, the evaporation and condensation temperatures of the refrigerant should be 4°C and 36°C, respectively. The saturation pressures corresponding to these temperatures are 338 kPa and 912 kPa. Therefore, the recommended evaporator and condenser pressures are **338 kPa** and **912 kPa**, respectively.

Heat Pump Systems

11-43C A heat pump system is more cost effective in Miami because of the low heating loads and high cooling loads at that location.

11-44C A water-source heat pump extracts heat from water instead of air. Water-source heat pumps have higher COPs than the air-source systems because the temperature of water is higher than the temperature of air in winter.

11-45E A heat pump operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP of the heat pump is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} T_1 = 40^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 40^\circ\text{F} = 108.78 \text{ Btu/lbm} \\ s_1 = s_g @ 40^\circ\text{F} = 0.22189 \text{ kJ/kg}\cdot\text{K} \end{array}$$

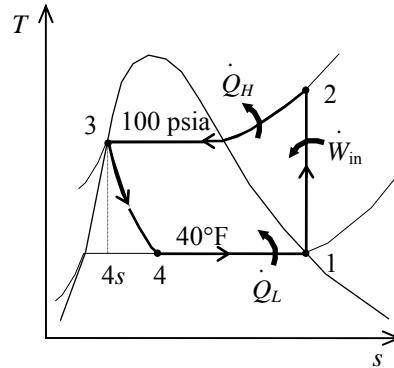

$$\left. \begin{array}{l} P_2 = 100 \text{ psia} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_2 = 114.98 \text{ Btu/lbm} \end{array}$$

$$\left. \begin{array}{l} P_3 = 100 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 100 \text{ psia} = 37.869 \text{ Btu/lbm} \end{array}$$

$$h_4 \cong h_3 = 37.869 \text{ Btu/lbm} \quad (\text{throttling})$$

The COP of the heat pump is determined from its definition,

$$\text{COP}_{\text{HP}} = \frac{\dot{Q}_H}{W_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{114.98 - 37.869}{114.98 - 108.78} = \mathbf{12.43}$$

11-46 A heat pump operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP and the rate of heat supplied to the evaporator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 200 \text{ kPa} = 244.46 \text{ kJ/kg} \\ s_1 = s_g @ 200 \text{ kPa} = 0.93773 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = 1000 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} \left. \begin{array}{l} h_2 = 277.98 \text{ kJ/kg} \end{array} \right.$$

$$\left. \begin{array}{l} P_3 = 1000 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} \left. \begin{array}{l} h_3 = h_f @ 1000 \text{ kPa} = 107.32 \text{ kJ/kg} \end{array} \right.$$

$$h_4 \cong h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is determined from

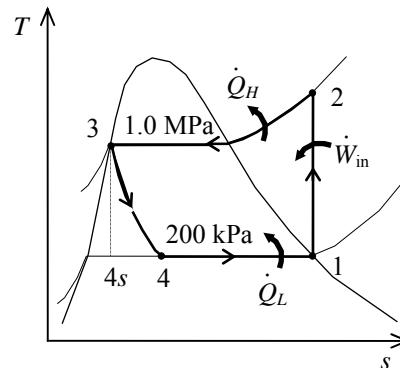

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) \longrightarrow \dot{m} = \frac{\dot{W}_{\text{in}}}{h_2 - h_1} = \frac{6 \text{ kJ/s}}{(277.98 - 244.46) \text{ kJ/kg}} = 0.179 \text{ kg/s}$$

Then the rate of heat supplied to the evaporator is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.179 \text{ kg/s})(244.46 - 107.32) \text{ kJ/kg} = \mathbf{24.5 \text{ kW}}$$

The COP of the heat pump is determined from its definition,

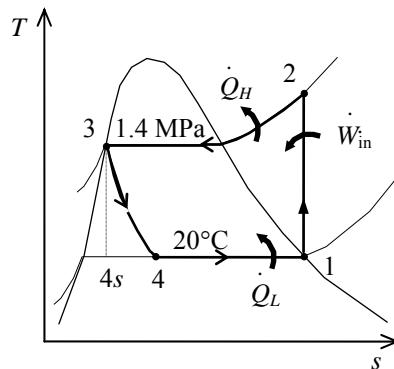

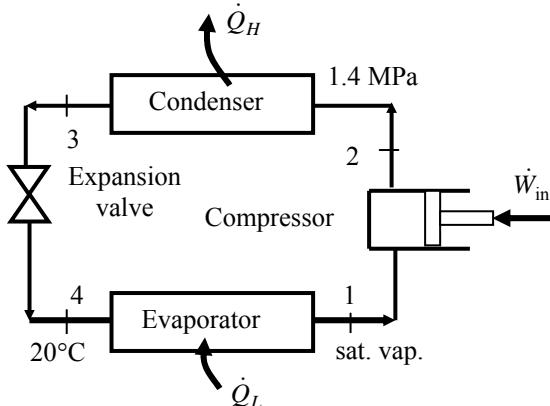

$$\text{COP}_{\text{HP}} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{277.98 - 107.32}{277.98 - 244.46} = \mathbf{5.09}$$

11-47 A heat pump operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The rate of heat transfer to the heated space and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

(b) The properties as given in the problem statement are

$$h_4 = h_f @ 1400 \text{ kPa} = 127.2 \text{ kJ/kg}$$

$$h_1 = h_g @ 20^\circ\text{C} = 261.6 \text{ kJ/kg}$$

The enthalpy at the compressor exit is

$$w_{\text{in}} = h_2 - h_1 \longrightarrow h_2 = h_1 + w_{\text{in}} = 261.6 \text{ kJ/kg} + 20 \text{ kJ/kg} = 281.6 \text{ kJ/kg}$$

The mass flow rate through the cycle is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{2.7 \text{ kJ/s}}{(261.6 - 127.2) \text{ kJ/kg}} = 0.02009 \text{ kg/s}$$

The rate of heat transfer to the heated space is

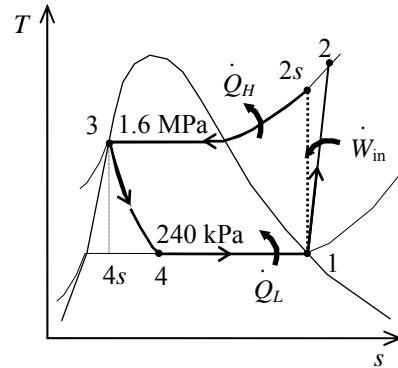

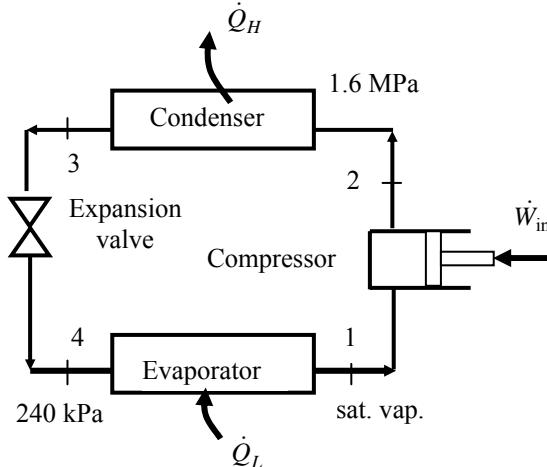

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.02009 \text{ kg/s})(281.6 - 127.2) \text{ kJ/kg} = \mathbf{3.10 \text{ kW}}$$

(c) The COP of the heat pump is

$$\text{COP}_{\text{HP}} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{\dot{Q}_H}{\dot{m}w_{\text{in}}} = \frac{3.10 \text{ kW}}{(0.02009 \text{ kg/s})(20 \text{ kJ/kg})} = \mathbf{7.72}$$

11-48 A heat pump vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The hardware and the *T-s* diagram for this heat pump are to be sketched. The power input and the COP are to be determined.

Analysis (a) In a normal vapor-compression refrigeration cycle, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

(b) The properties as given in the problem statement are

$$h_4 = h_3 = h_f @ 1600 \text{ kPa} = 134 \text{ kJ/kg}$$

$$h_1 = h_g @ 240 \text{ kPa} = 244 \text{ kJ/kg}$$

$$h_{2s} = 285 \text{ kJ/kg}$$

From the definition of isentropic efficiency for a compressor,

$$\eta_{\text{Comp}} = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_{\text{Comp}}} = 244 + \frac{285 - 244}{0.85} = 292.2 \text{ kJ/kg}$$

Then the work input to the compressor is

$$w_{\text{in}} = h_2 - h_1 = 292.2 - 244 = 48.2 \text{ kJ/kg}$$

The mass flow rate through the cycle is

$$\dot{Q}_H = \dot{m}(h_2 - h_3) \longrightarrow \dot{m} = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{(2 \text{ ton}) \left(\frac{211/60 \text{ kJ/s}}{1 \text{ ton}} \right)}{(292.2 - 134) \text{ kJ/kg}} = 0.04446 \text{ kg/s}$$

Then the power input to the compressor is

$$\dot{W}_{\text{in}} = \dot{m} w_{\text{in}} = (0.04446 \text{ kg/s})(48.2 \text{ kJ/kg}) = \mathbf{2.14 \text{ kW}}$$

The COP of the heat pump is

$$\text{COP}_{\text{HP}} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{(2 \text{ ton}) \left(\frac{211/60 \text{ kJ/s}}{1 \text{ ton}} \right)}{2.14 \text{ kW}} = \mathbf{3.29}$$

11-49 A geothermal heat pump is considered. The degrees of subcooling done on the refrigerant in the condenser, the mass flow rate of the refrigerant, the heating load, the COP of the heat pump, the minimum power input are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} T_4 &= 20^\circ\text{C} \quad P_4 = 572.1 \text{ kPa} \\ x_4 &= 0.23 \quad h_4 = 121.24 \text{ kJ/kg} \\ h_3 &= h_4 \\ P_1 &= 572.1 \text{ kPa} \quad h_1 = 261.59 \text{ kJ/kg} \\ x_1 &= 1(\text{sat. vap.}) \quad s_1 = 0.9223 \text{ kJ/kg} \\ P_2 &= 1400 \text{ kPa} \quad h_2 = 280.00 \text{ kJ/kg} \\ s_2 &= s_1 \end{aligned}$$

From the steam tables (Table A-4)

$$\begin{aligned} h_{w1} &= h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg} \\ h_{w2} &= h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg} \end{aligned}$$

The saturation temperature at the condenser pressure of 1400 kPa and the actual temperature at the condenser outlet are

$$\begin{aligned} T_{\text{sat}} @ 1400 \text{ kPa} &= 52.40^\circ\text{C} \\ P_3 &= 1400 \text{ kPa} \quad h_3 = 121.24 \text{ kJ/kg} \\ h_3 &= 121.24 \text{ kJ/kg} \end{aligned} \quad \left. \begin{array}{l} T_3 = 48.59^\circ\text{C} \text{ (from EES)} \end{array} \right\}$$

Then, the degrees of subcooling is

$$\Delta T_{\text{subcool}} = T_{\text{sat}} - T_3 = 52.40 - 48.59 = \mathbf{3.81^\circ\text{C}}$$

(b) The rate of heat absorbed from the geothermal water in the evaporator is

$$\dot{Q}_L = \dot{m}_w (h_{w1} - h_{w2}) = (0.065 \text{ kg/s})(209.34 - 167.53) \text{ kJ/kg} = 2.718 \text{ kW}$$

This heat is absorbed by the refrigerant in the evaporator

$$\dot{m}_R = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{2.718 \text{ kW}}{(261.59 - 121.24) \text{ kJ/kg}} = \mathbf{0.01936 \text{ kg/s}}$$

(c) The power input to the compressor, the heating load and the COP are

$$\dot{W}_{\text{in}} = \dot{m}_R (h_2 - h_1) + \dot{Q}_{\text{out}} = (0.01936 \text{ kg/s})(280.00 - 261.59) \text{ kJ/kg} = 0.6564 \text{ kW}$$

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = (0.01936 \text{ kg/s})(280.00 - 121.24) \text{ kJ/kg} = \mathbf{3.074 \text{ kW}}$$

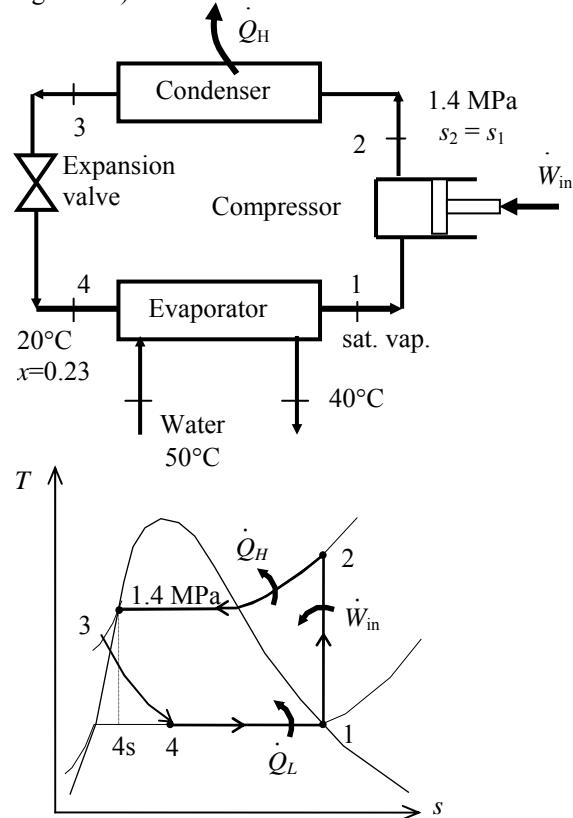

$$\text{COP} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{3.074 \text{ kW}}{0.6564 \text{ kW}} = \mathbf{4.68}$$

(d) The reversible COP of the cycle is

$$\text{COP}_{\text{rev}} = \frac{1}{1 - T_L/T_H} = \frac{1}{1 - (25 + 273)/(50 + 273)} = 12.92$$

The corresponding minimum power input is

$$\dot{W}_{\text{in,min}} = \frac{\dot{Q}_H}{\text{COP}_{\text{rev}}} = \frac{3.074 \text{ kW}}{12.92} = \mathbf{0.238 \text{ kW}}$$

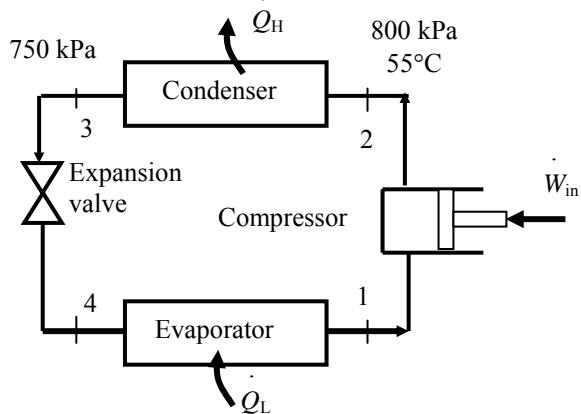

11-50 An actual heat pump cycle with R-134a as the refrigerant is considered. The isentropic efficiency of the compressor, the rate of heat supplied to the heated room, the COP of the heat pump, and the COP and the rate of heat supplied to the heated room if this heat pump operated on the ideal vapor-compression cycle between the same pressure limits are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of refrigerant-134a are (Tables A-11 through A-13)

$$\begin{aligned} P_2 &= 800 \text{ kPa} \\ T_2 &= 55^\circ\text{C} \quad h_2 = 291.76 \text{ kJ/kg} \\ T_3 &= T_{\text{sat}@750 \text{ kPa}} = 29.06^\circ\text{C} \\ P_3 &= 750 \text{ kPa} \\ T_3 &= (29.06 - 3)^\circ\text{C} \quad h_3 = 87.91 \text{ kJ/kg} \\ h_4 &= h_3 = 87.91 \text{ kJ/kg} \\ T_{\text{sat}@200 \text{ kPa}} &= -10.09^\circ\text{C} \\ P_1 &= 200 \text{ kPa} \quad h_1 = 247.87 \text{ kJ/kg} \\ T_1 &= (-10.09 + 4)^\circ\text{C} \quad s_1 = 0.9506 \text{ kJ/kg} \\ P_2 &= 800 \text{ kPa} \\ s_2 &= s_1 \quad h_{2s} = 277.26 \end{aligned}$$

The isentropic efficiency of the compressor is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{277.26 - 247.87}{291.76 - 247.87} = \mathbf{0.670}$$

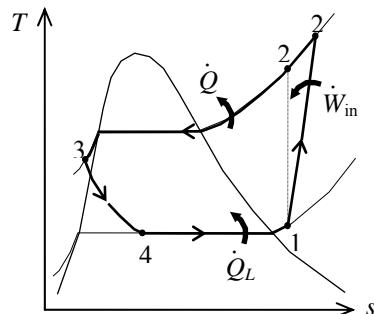

(b) The rate of heat supplied to the room is

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.018 \text{ kg/s})(291.76 - 87.91) \text{ kJ/kg} = \mathbf{3.67 \text{ kW}}$$

(c) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.018 \text{ kg/s})(291.76 - 247.87) \text{ kJ/kg} = 0.790 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{3.67}{0.790} = \mathbf{4.64}$$

(d) The ideal vapor-compression cycle analysis of the cycle is as follows:

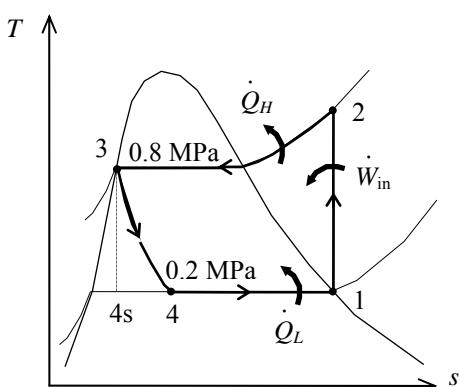

$$\begin{aligned} h_1 &= h_g @ 200 \text{ kPa} = 244.46 \text{ kJ/kg} \\ s_1 &= s_g @ 200 \text{ kPa} = 0.9377 \text{ kJ/kg.K} \end{aligned}$$

$$\begin{aligned} P_2 &= 800 \text{ kPa} \\ s_2 &= s_1 \quad h_2 = 273.25 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} h_3 &= h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg} \\ h_4 &= h_3 \end{aligned}$$

$$\text{COP} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{273.25 - 95.47}{273.25 - 244.46} = \mathbf{6.18}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.018 \text{ kg/s})(273.25 - 95.47) \text{ kJ/kg} = \mathbf{3.20 \text{ kW}}$$

Innovative Refrigeration Systems

11-51C Performing the refrigeration in stages is called cascade refrigeration. In cascade refrigeration, two or more refrigeration cycles operate in series. Cascade refrigerators are more complex and expensive, but they have higher COP's, they can incorporate two or more different refrigerants, and they can achieve much lower temperatures.

11-52C Cascade refrigeration systems have higher COPs than the ordinary refrigeration systems operating between the same pressure limits.

11-53C The saturation pressure of refrigerant-134a at -32°C is 77 kPa, which is below the atmospheric pressure. In reality a pressure below this value should be used. Therefore, a cascade refrigeration system with a different refrigerant at the bottoming cycle is recommended in this case.

11-54C We would favor the two-stage compression refrigeration system with a flash chamber since it is simpler, cheaper, and has better heat transfer characteristics.

11-55C Yes, by expanding the refrigerant in stages in several throttling devices.

11-56C To take advantage of the cooling effect by throttling from high pressures to low pressures.

11-57 A two-stage compression refrigeration system with refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the rate of heat removed from the refrigerated space, and the COP are to be determined.

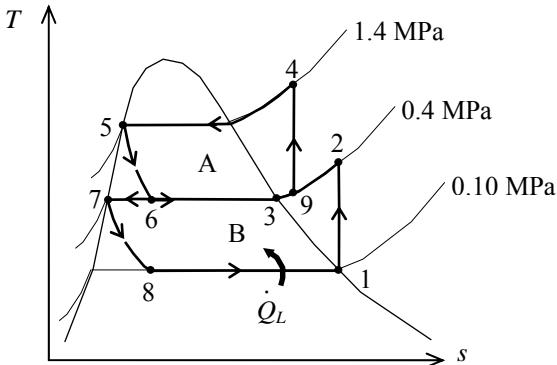

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flash chamber is adiabatic.

Analysis (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$\begin{aligned} h_1 &= 234.44 \text{ kJ/kg}, \quad h_2 = 262.68 \text{ kJ/kg} \\ h_3 &= 255.55 \text{ kJ/kg}, \\ h_5 &= 127.22 \text{ kJ/kg}, \quad h_6 = 127.22 \text{ kJ/kg} \\ h_7 &= 63.94 \text{ kJ/kg}, \quad h_8 = 63.94 \text{ kJ/kg} \end{aligned}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{127.22 - 63.94}{191.62} = \mathbf{0.3303}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{sh0 (steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ (1)h_9 &= x_6 h_3 + (1 - x_6)h_2 \\ h_9 &= (0.3303)(255.55) + (1 - 0.3303)(262.68) = 260.33 \text{ kJ/kg} \\ P_9 &= 0.4 \text{ MPa} \\ h_9 &= 260.33 \text{ kJ/kg} \end{aligned} \quad \left. \begin{array}{l} s_9 = 0.9437 \text{ kJ/kg} \cdot \text{K} \end{array} \right\}$$

also,

$$\begin{aligned} P_4 &= 1.4 \text{ MPa} \\ s_4 &= s_9 = 0.9437 \text{ kJ/kg} \cdot \text{K} \end{aligned} \quad \left. \begin{array}{l} h_4 = 287.07 \text{ kJ/kg} \end{array} \right\}$$

Then the rate of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$\dot{m}_B = (1 - x_6) \dot{m}_A = (1 - 0.3303)(0.25 \text{ kg/s}) = 0.1674 \text{ kg/s}$$

$$\dot{Q}_L = \dot{m}_B (h_1 - h_8) = (0.1674 \text{ kg/s})(234.44 - 63.94) \text{ kJ/kg} = \mathbf{28.55 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{W}_{\text{compI,in}} + \dot{W}_{\text{compII,in}} = \dot{m}_A (h_4 - h_9) + \dot{m}_B (h_2 - h_1) \\ &= (0.25 \text{ kg/s})(287.07 - 260.33) \text{ kJ/kg} + (0.1674 \text{ kg/s})(262.68 - 234.44) \text{ kJ/kg} \\ &= 11.41 \text{ kW} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{28.55 \text{ kW}}{11.41 \text{ kW}} = \mathbf{2.50}$$

11-58 A two-stage compression refrigeration system with refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the rate of heat removed from the refrigerated space, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flash chamber is adiabatic.

Analysis (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$\begin{aligned} h_1 &= 234.44 \text{ kJ/kg}, & h_2 &= 271.40 \text{ kJ/kg} \\ h_3 &= 262.40 \text{ kJ/kg}, \\ h_5 &= 127.22 \text{ kJ/kg}, & h_6 &= 127.22 \text{ kJ/kg} \\ h_7 &= 81.51 \text{ kJ/kg}, & h_8 &= 81.51 \text{ kJ/kg} \end{aligned}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{127.22 - 81.51}{180.90} = \mathbf{0.2527}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ (1)h_9 &= x_6 h_3 + (1 - x_6) h_2 \\ h_9 &= (0.2527)(262.40) + (1 - 0.2527)(271.40) = 269.13 \text{ kJ/kg} \\ P_9 &= 0.6 \text{ MPa} \\ h_9 &= 269.13 \text{ kJ/kg} \quad \left. \begin{array}{l} s_9 = 0.9443 \text{ kJ/kg} \cdot \text{K} \\ \end{array} \right\} \end{aligned}$$

also,

$$\begin{aligned} P_4 &= 1.4 \text{ MPa} \\ s_4 &= s_9 = 0.9443 \text{ kJ/kg} \cdot \text{K} \end{aligned} \quad \left. \begin{array}{l} h_4 = 287.28 \text{ kJ/kg} \\ \end{array} \right\}$$

Then the rate of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

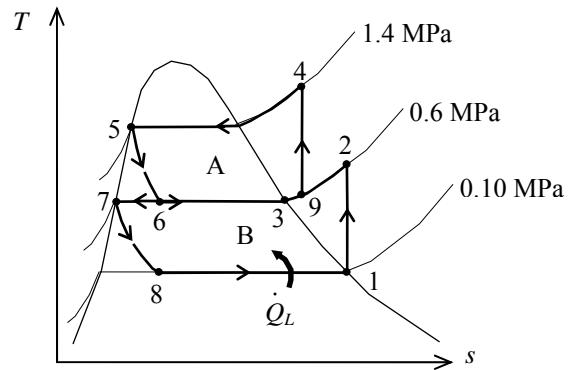

$$\dot{m}_B = (1 - x_6) \dot{m}_A = (1 - 0.2527)(0.25 \text{ kg/s}) = 0.1868 \text{ kg/s}$$

$$\dot{Q}_L = \dot{m}_B (h_1 - h_8) = (0.1868 \text{ kg/s})(234.44 - 81.51) \text{ kJ/kg} = \mathbf{28.57 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{W}_{\text{compI,in}} + \dot{W}_{\text{compII,in}} = \dot{m}_A (h_4 - h_9) + \dot{m}_B (h_2 - h_1) \\ &= (0.25 \text{ kg/s})(287.28 - 269.13) \text{ kJ/kg} + (0.1868 \text{ kg/s})(271.40 - 234.44) \text{ kJ/kg} \\ &= 11.44 \text{ kW} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{28.57 \text{ kW}}{11.44 \text{ kW}} = \mathbf{2.50}$$

11-59 Problem 11-57 is reconsidered. The effects of the various refrigerants in EES data bank for compressor efficiencies of 80, 90, and 100 percent is to be investigated.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

11-60 A two-stage cascade refrigeration cycle is considered. The mass flow rate of the refrigerant through the upper cycle, the rate of heat removal from the refrigerated space, and the COP of the refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties are to be obtained from the refrigerant tables (Tables A-11 through A-13):

$$h_1 = h_g @ 200 \text{ kPa} = 244.46 \text{ kJ/kg}$$

$$s_1 = s_g @ 200 \text{ kPa} = 0.9377 \text{ kJ/kg.K}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 263.30 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{263.30 - 244.46}{h_2 - 244.46} \longrightarrow h_2 = 268.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 500 \text{ kPa} = 73.33 \text{ kJ/kg}$$

$$h_4 = h_3 = 73.33 \text{ kJ/kg}$$

$$h_5 = h_g @ 400 \text{ kPa} = 255.55 \text{ kJ/kg}$$

$$s_5 = s_g @ 400 \text{ kPa} = 0.9269 \text{ kJ/kg.K}$$

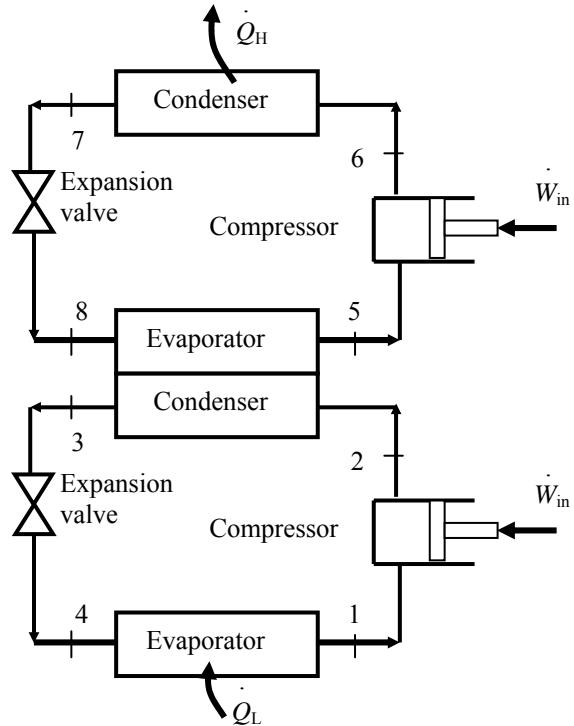

$$\left. \begin{array}{l} P_6 = 1200 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} h_{6s} = 278.33 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5}$$

$$0.80 = \frac{278.33 - 255.55}{h_6 - 255.55} \longrightarrow h_6 = 284.02 \text{ kJ/kg}$$

$$h_7 = h_f @ 1200 \text{ kPa} = 117.77 \text{ kJ/kg}$$

$$h_8 = h_7 = 117.77 \text{ kJ/kg}$$

The mass flow rate of the refrigerant through the upper cycle is determined from an energy balance on the heat exchanger

$$\dot{m}_A (h_5 - h_8) = \dot{m}_B (h_2 - h_3)$$

$$\dot{m}_A (255.55 - 117.77) \text{ kJ/kg} = (0.15 \text{ kg/s})(268.01 - 73.33) \text{ kJ/kg} \longrightarrow \dot{m}_A = \mathbf{0.212 \text{ kg/s}}$$

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}_B (h_1 - h_4) = (0.15 \text{ kg/s})(244.46 - 73.33) \text{ kJ/kg} = \mathbf{25.67 \text{ kW}}$$

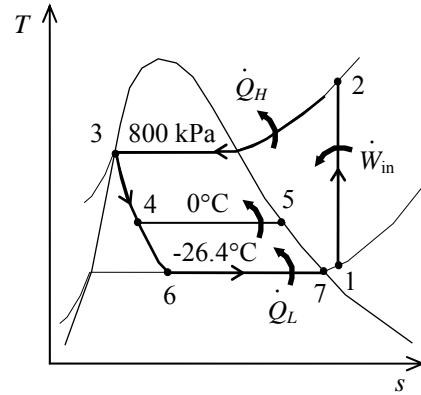

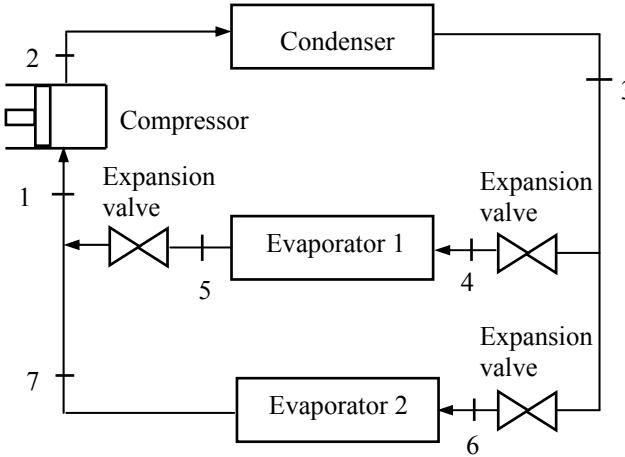

(c) The power input and the COP are

$$\begin{aligned} \dot{W}_{in} &= \dot{m}_A (h_6 - h_5) + \dot{m}_B (h_2 - h_1) \\ &= (0.15 \text{ kg/s})(284.02 - 255.55) \text{ kJ/kg} + (0.212 \text{ kg/s})(268.01 - 244.46) \text{ kJ/kg} = 9.566 \text{ kW} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{25.67}{9.566} = \mathbf{2.68}$$

11-61 A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The cooling rate of the high-temperature evaporator, the power required by the compressor, and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$h_4 = h_6 \approx h_3 = 95.47 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 0^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 0^\circ\text{C} = 250.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = -26.4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ -26.4^\circ\text{C} = 234.44 \text{ kJ/kg}$$

The mass flow rate through the low-temperature evaporator is found by

$$\dot{Q}_L = \dot{m}_2 (h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_L}{h_7 - h_6} = \frac{8 \text{ kJ/s}}{(234.44 - 95.47) \text{ kJ/kg}} = 0.05757 \text{ kg/s}$$

The mass flow rate through the warmer evaporator is then

$$\dot{m}_1 = \dot{m} - \dot{m}_2 = 0.1 - 0.05757 = 0.04243 \text{ kg/s}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = \dot{m} h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}} = \frac{(0.04243)(250.45) + (0.05757)(234.44)}{0.1} = 241.23 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = P_{\text{sat} @ -26.4^\circ\text{C}} \approx 100 \text{ kPa} \\ h_1 = 241.23 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9789 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 286.26 \text{ kJ/kg}$$

The cooling rate of the high-temperature evaporator is

$$\dot{Q}_L = \dot{m}_1 (h_5 - h_4) = (0.04243 \text{ kg/s})(250.45 - 95.47) \text{ kJ/kg} = \mathbf{6.58 \text{ kW}}$$

The power input to the compressor is

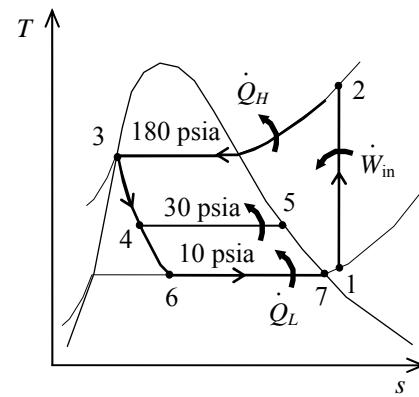

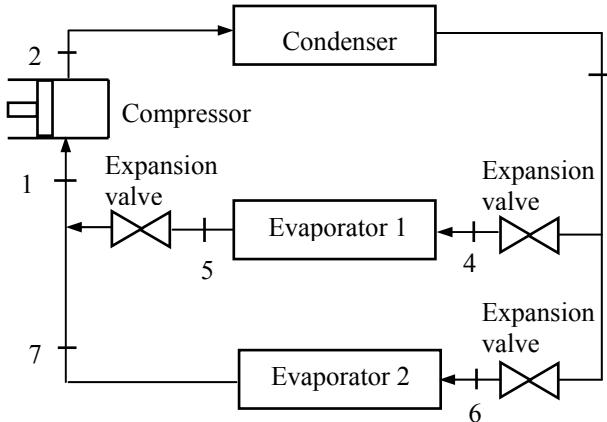

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.1 \text{ kg/s})(286.26 - 241.23) \text{ kJ/kg} = \mathbf{4.50 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(8 + 6.58) \text{ kW}}{4.50 \text{ kW}} = \mathbf{3.24}$$

11-62E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The power required by the compressor and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 180 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 180 \text{ psia} = 51.50 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 51.50 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 30 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 30 \text{ psia} = 105.32 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_7 = 10 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ 10 \text{ psia} = 98.68 \text{ Btu/lbm}$$

The mass flow rates through the high-temperature and low-temperature evaporators are found by

$$\dot{Q}_{L,1} = \dot{m}_1(h_5 - h_4) \longrightarrow \dot{m}_1 = \frac{\dot{Q}_{L,1}}{h_5 - h_4} = \frac{9000 \text{ Btu/h}}{(105.32 - 51.50) \text{ Btu/lbm}} = 167.2 \text{ lbm/h}$$

$$\dot{Q}_{L,2} = \dot{m}_2(h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_{L,2}}{h_7 - h_6} = \frac{24,000 \text{ Btu/h}}{(98.68 - 51.50) \text{ Btu/lbm}} = 508.6 \text{ lbm/h}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = (\dot{m}_1 + \dot{m}_2) h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}_1 + \dot{m}_2} = \frac{(167.2)(105.32) + (508.6)(98.68)}{167.2 + 508.6} = 100.33 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = 10 \text{ psia} \\ h_1 = 100.33 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2333 \text{ Btu/lbm} \cdot R$$

$$\left. \begin{array}{l} P_2 = 180 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 127.05 \text{ Btu/lbm}$$

The power input to the compressor is

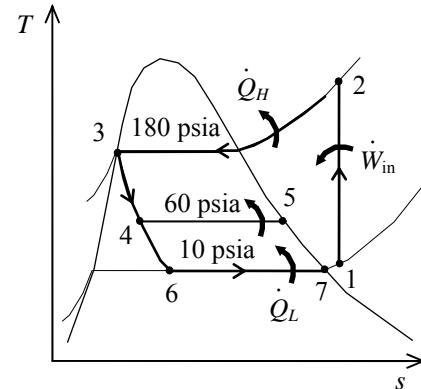

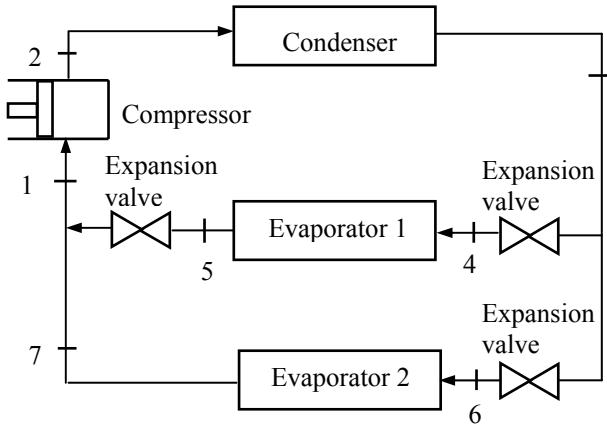

$$\dot{W}_{in} = (\dot{m}_1 + \dot{m}_2)(h_2 - h_1) = (167.2 + 508.6) \text{ lbm/h} (127.05 - 100.33) \text{ Btu/lbm} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = 5.29 \text{ kW}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{(24,000 + 9000) \text{ Btu/h}}{5.29 \text{ kW}} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = 1.83$$

11-63E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The power required by the compressor and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 180 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 180 \text{ psia} = 51.50 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 51.50 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 60 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 60 \text{ psia} = 110.11 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_7 = 10 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ 10 \text{ psia} = 98.68 \text{ Btu/lbm}$$

The mass flow rates through the high-temperature and low-temperature evaporators are found by

$$\dot{Q}_{L,1} = \dot{m}_1(h_5 - h_4) \longrightarrow \dot{m}_1 = \frac{\dot{Q}_{L,1}}{h_5 - h_4} = \frac{30,000 \text{ Btu/h}}{(110.11 - 51.50) \text{ Btu/lbm}} = 511.8 \text{ lbm/h}$$

$$\dot{Q}_{L,2} = \dot{m}_2(h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_{L,2}}{h_7 - h_6} = \frac{24,000 \text{ Btu/h}}{(98.68 - 51.50) \text{ Btu/lbm}} = 508.6 \text{ lbm/h}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = (\dot{m}_1 + \dot{m}_2) h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}_1 + \dot{m}_2} = \frac{(511.8)(110.11) + (508.6)(98.68)}{511.8 + 508.6} = 104.41 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = 10 \text{ psia} \\ h_1 = 104.41 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2423 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 180 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 132.69 \text{ Btu/lbm}$$

The power input to the compressor is

$$\dot{W}_{in} = (\dot{m}_1 + \dot{m}_2)(h_2 - h_1) = (511.8 + 508.6) \text{ lbm/h} (132.69 - 104.41) \text{ Btu/lbm} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = 8.46 \text{ kW}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{(24,000 + 30,000) \text{ Btu/h}}{8.46 \text{ kW}} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = 1.87$$

11-64 A two-stage cascade refrigeration system is considered. Each stage operates on the ideal vapor-compression cycle with upper cycle using water and lower cycle using refrigerant-134a as the working fluids. The mass flow rate of R-134a and water in their respective cycles and the overall COP of this system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The heat exchanger is adiabatic.

Analysis From the water and refrigerant tables (Tables A-4, A-5, A-6, A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 5^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 5^\circ\text{C} = 2510.1 \text{ kJ/kg} \\ s_1 = s_g @ 5^\circ\text{C} = 9.0249 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = 1.6 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \left. \begin{array}{l} h_2 = 5083.4 \text{ kJ/kg} \end{array} \right.$$

$$\left. \begin{array}{l} P_3 = 1.6 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \left. \begin{array}{l} h_3 = h_f @ 1.6 \text{ MPa} = 858.44 \text{ kJ/kg} \end{array} \right.$$

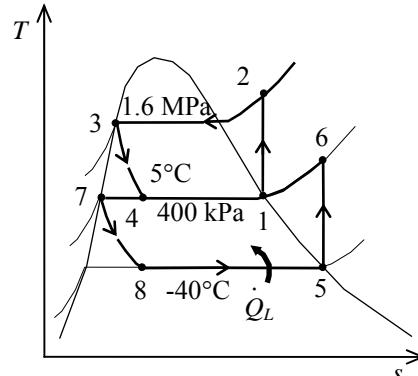

$$h_4 \cong h_3 = 858.44 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = -40^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_5 = h_g @ -40^\circ\text{C} = 225.86 \text{ kJ/kg} \\ s_5 = s_g @ -40^\circ\text{C} = 0.96866 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_6 = 400 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \left. \begin{array}{l} h_6 = 267.59 \text{ kJ/kg} \end{array} \right.$$

$$\left. \begin{array}{l} P_7 = 400 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} \left. \begin{array}{l} h_7 = h_f @ 400 \text{ kPa} = 63.94 \text{ kJ/kg} \end{array} \right.$$

$$h_8 \cong h_7 = 63.94 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of R-134a is determined from

$$\dot{Q}_L = \dot{m}_R (h_5 - h_8) \longrightarrow \dot{m}_R = \frac{\dot{Q}_L}{h_5 - h_8} = \frac{20 \text{ kJ/s}}{(225.86 - 63.94) \text{ kJ/kg}} = \mathbf{0.1235 \text{ kg/s}}$$

An energy balance on the heat exchanger gives the mass flow rate of water

$$\begin{aligned} \dot{m}_R (h_6 - h_7) &= \dot{m}_w (h_1 - h_4) \\ \longrightarrow \dot{m}_w &= \dot{m}_R \frac{h_6 - h_7}{h_1 - h_4} = (0.1235 \text{ kg/s}) \frac{267.59 - 63.94}{2510.1 - 858.44} = \mathbf{0.01523 \text{ kg/s}} \end{aligned}$$

The total power input to the compressors is

$$\begin{aligned} \dot{W}_{in} &= \dot{m}_R (h_6 - h_5) + \dot{m}_w (h_2 - h_1) \\ &= (0.1235 \text{ kg/s})(267.59 - 225.86) \text{ kJ/kg} + (0.01523 \text{ kg/s})(5083.4 - 2510.1) \text{ kJ/kg} \\ &= 44.35 \text{ kJ/s} \end{aligned}$$

The COP of this refrigeration system is determined from its definition,

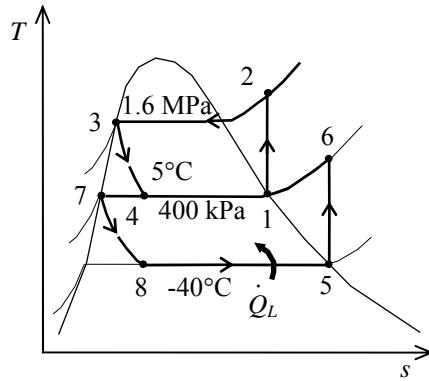

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{20 \text{ kJ/s}}{44.35 \text{ kJ/s}} = \mathbf{0.451}$$

11-65 A two-stage vapor-compression refrigeration system with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Prob. 11-55 and the water and refrigerant tables (Tables A-4, A-5, A-6, A-11, A-12, and A-13),

$$\begin{aligned}s_1 &= s_2 = 9.0249 \text{ kJ/kg} \cdot \text{K} \\s_3 &= 2.3435 \text{ kJ/kg} \cdot \text{K} \\s_4 &= 3.0869 \text{ kJ/kg} \cdot \text{K} \\s_5 &= s_6 = 0.96866 \text{ kJ/kg} \cdot \text{K} \\s_7 &= 0.24757 \text{ kJ/kg} \cdot \text{K} \\s_8 &= 0.27423 \text{ kJ/kg} \cdot \text{K} \\\dot{m}_R &= 0.1235 \text{ kg/s} \\\dot{m}_w &= 0.01523 \text{ kg/s} \\q_L &= h_5 - h_8 = 161.92 \text{ kJ/kg} \\q_H &= h_2 - h_3 = 4225.0 \text{ kJ/kg} \\T_L &= -30^\circ\text{C} = 243 \text{ K} \\T_H &= 30^\circ\text{C} = 303 \text{ K} \\T_0 &= 30^\circ\text{C} = 303 \text{ K}\end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$\dot{X}_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned}\dot{X}_{\text{destroyed},23} &= \dot{m}_w T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) \\&= (0.01523)(303 \text{ K}) \left(2.3435 - 9.0249 + \frac{4225.0}{303} \right) = 33.52 \text{ kJ/s} \\\dot{X}_{\text{destroyed},34} &= \dot{m}_w T_0 (s_4 - s_3) = (0.01523)(303)(3.0869 - 2.3435) = 3.43 \text{ kJ/s} \\\dot{X}_{\text{destroyed},78} &= \dot{m}_R T_0 (s_8 - s_7) = (0.1235)(303)(0.27423 - 0.24757) = 0.996 \text{ kJ/s} \\\dot{X}_{\text{destroyed},85} &= \dot{m}_R T_0 \left(s_5 - s_8 - \frac{q_L}{T_L} \right) \\&= (0.1235)(303) \left(0.96866 - 0.27423 - \frac{161.92}{243} \right) = 1.05 \text{ kJ/s} \\\dot{X}_{\text{destroyed,heat exch}} &= T_0 [\dot{m}_w (s_1 - s_4) + \dot{m}_R (s_7 - s_6)] \\&= (303) [(0.01523)(9.0249 - 3.0869) + (0.1235)(0.24757 - 0.96866)] = 0.417 \text{ kJ/s}\end{aligned}$$

For isentropic processes, the exergy destruction is zero:

$$\dot{X}_{\text{destroyed},12} = 0$$

$$\dot{X}_{\text{destroyed},56} = 0$$

Note that heat is absorbed from a reservoir at -30°C (243 K) and rejected to a reservoir at 30°C (303 K), which is also taken as the dead state temperature. Alternatively, one may use the standard 25°C (298 K) as the dead state temperature, and perform the calculations accordingly. The greatest exergy destruction occurs in the condenser.

11-66 A two-stage cascade refrigeration cycle with a flash chamber with refrigerant-134a as the working fluid is considered. The mass flow rate of the refrigerant through the high-pressure compressor, the rate of refrigeration, the COP are to be determined. Also, the rate of refrigeration and the COP are to be determined if this refrigerator operated on a single-stage vapor-compression cycle under similar conditions.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant-134a tables (Tables A-11 through A-13)

$$h_1 = h_{g@-10^\circ\text{C}} = 244.51 \text{ kJ/kg}$$

$$s_1 = s_{g@-10^\circ\text{C}} = 0.9377 \text{ kJ/kg.K}$$

$$\left. \begin{array}{l} P_2 = 450 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 261.07 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.86 = \frac{261.07 - 244.51}{h_2 - 244.51} \longrightarrow h_2 = 263.76 \text{ kJ/kg}$$

$$h_3 = h_{g@450 \text{ kPa}} = 257.53 \text{ kJ/kg}$$

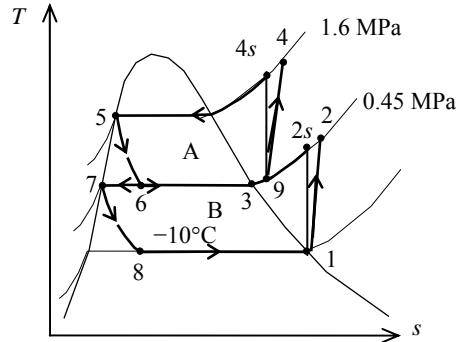

$$h_5 = h_{f@1600 \text{ kPa}} = 135.93 \text{ kJ/kg}$$

$$h_6 = h_5 = 135.93 \text{ kJ/kg}$$

$$h_7 = h_{f@450 \text{ kPa}} = 68.81 \text{ kJ/kg}$$

$$h_8 = h_7 = 68.81 \text{ kJ/kg}$$

$$\left. \begin{array}{l} h_6 = 135.93 \text{ kJ/kg} \\ P_6 = 450 \text{ kPa} \end{array} \right\} x_6 = 0.3557$$

The mass flow rate of the refrigerant through the high pressure compressor is determined from a mass balance on the flash chamber

$$\dot{m} = \frac{\dot{m}_7}{1 - x_6} = \frac{0.11 \text{ kg/s}}{1 - 0.3557} = \mathbf{0.1707 \text{ kg/s}}$$

Also,

$$\dot{m}_3 = \dot{m} - \dot{m}_7 = 0.1707 - 0.11 = 0.06072 \text{ kg/s}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{m}h_9 = \dot{m}_7h_2 + \dot{m}_3h_3$$

$$(0.1707 \text{ kg/s})h_9 = (0.11 \text{ kg/s})(263.76 \text{ kJ/kg}) + (0.06072 \text{ kg/s})(257.53 \text{ kJ/kg}) \longrightarrow h_9 = 261.54 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_9 = 450 \text{ kPa} \\ h_9 = 261.54 \text{ kJ/kg} \end{array} \right\} s_9 = 0.9393 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 1600 \text{ kPa} \\ s_4 = s_9 \end{array} \right\} h_{4s} = 288.41 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{4s} - h_9}{h_4 - h_9}$$

$$0.86 = \frac{288.41 - 261.54}{h_4 - 261.54} \longrightarrow h_4 = 292.78 \text{ kJ/kg}$$

The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}_7(h_1 - h_8) = (0.11 \text{ kg/s})(244.51 - 68.81) \text{ kJ/kg} = \mathbf{19.33 \text{ kW}}$$

(c) The power input and the COP are

$$\begin{aligned}\dot{W}_{\text{in}} &= \dot{m}_7(h_2 - h_1) + \dot{m}(h_4 - h_9) \\ &= (0.11 \text{ kg/s})(263.76 - 244.51) \text{ kJ/kg} + (0.1707 \text{ kg/s})(292.78 - 261.54) \text{ kJ/kg} = 7.45 \text{ kW}\end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{19.33}{7.45} = \mathbf{2.59}$$

(d) If this refrigerator operated on a single-stage cycle between the same pressure limits, we would have

$$h_1 = h_{g@-10^\circ\text{C}} = 244.51 \text{ kJ/kg}$$

$$s_1 = s_{g@-10^\circ\text{C}} = 0.9377 \text{ kJ/kg.K}$$

$$\left. \begin{array}{l} P_2 = 1600 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 287.85 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.86 = \frac{287.85 - 244.51}{h_2 - 244.51} \rightarrow h_2 = 294.90 \text{ kJ/kg}$$

$$h_3 = h_{f@1600 \text{ kPa}} = 135.93 \text{ kJ/kg}$$

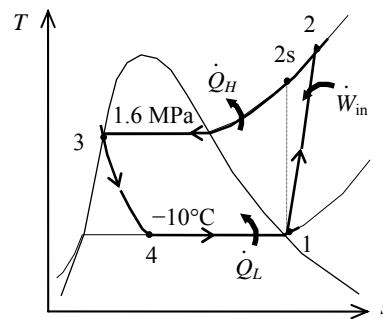

$$h_4 = h_3 = 135.93 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.1707 \text{ kg/s})(244.51 - 135.93) \text{ kJ/kg} = \mathbf{18.54 \text{ kW}}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.1707 \text{ kg/s})(294.90 - 244.51) \text{ kJ/kg} = 8.60 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{18.54}{8.60} = \mathbf{2.16}$$

Discussion The cooling load decreases by 4.1% while the COP decreases by 16.6% when the cycle operates on the single-stage vapor-compression cycle.

Gas Refrigeration Cycles

11-67C The ideal gas refrigeration cycle is identical to the Brayton cycle, except it operates in the reversed direction.

11-68C In the ideal gas refrigeration cycle, the heat absorption and the heat rejection processes occur at constant pressure instead of at constant temperature.

11-69C The reversed Stirling cycle is identical to the Stirling cycle, except it operates in the reversed direction. Remembering that the Stirling cycle is a totally reversible cycle, the reversed Stirling cycle is also totally reversible, and thus its COP is

$$\text{COP}_{R,\text{Stirling}} = \frac{1}{T_H / T_L - 1}$$

11-70C In aircraft cooling, the atmospheric air is compressed by a compressor, cooled by the surrounding air, and expanded in a turbine. The cool air leaving the turbine is then directly routed to the cabin.

11-71C No; because $h = h(T)$ for ideal gases, and the temperature of air will not drop during a throttling ($h_1 = h_2$) process.

11-72C By regeneration.

11-73 An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

Analysis (a) We assume both the turbine and the compressor to be isentropic, the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 280 \text{ K} \longrightarrow h_1 = 280.13 \text{ kJ/kg}$$

$$P_{r_1} = 1.0889$$

$$T_3 = 310 \text{ K} \longrightarrow h_3 = 310.24 \text{ kJ/kg}$$

$$P_{r_3} = 1.5546$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left(\frac{160}{35} \right) (1.0889) = 4.978 \longrightarrow T_2 = 431.5 \text{ K}$$

$$h_2 = 432.96 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{35}{160} \right) (1.5546) = 0.3401 \longrightarrow T_4 = 200.6 \text{ K}$$

$$h_4 = 200.57 \text{ kJ/kg}$$

Then the rate of refrigeration is

$$\dot{Q}_L = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.2 \text{ kg/s})(280.13 - 200.57) \text{ kJ/kg} = \mathbf{15.9 \text{ kW}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net,in}} = \dot{W}_{\text{comp,in}} - \dot{W}_{\text{turb,out}}$$

where

$$\dot{W}_{\text{comp,in}} = \dot{m}(h_2 - h_1) = (0.2 \text{ kg/s})(432.96 - 280.13) \text{ kJ/kg} = 30.57 \text{ kW}$$

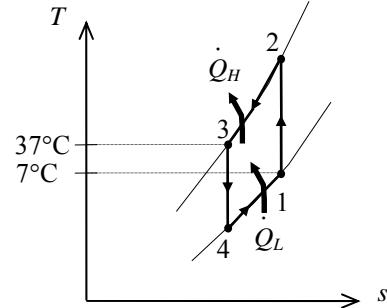

$$\dot{W}_{\text{turb,out}} = \dot{m}(h_3 - h_4) = (0.2 \text{ kg/s})(310.24 - 200.57) \text{ kJ/kg} = 21.93 \text{ kW}$$

Thus,

$$\dot{W}_{\text{net,in}} = 30.57 - 21.93 = \mathbf{8.64 \text{ kW}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{15.9 \text{ kW}}{8.64 \text{ kW}} = \mathbf{1.84}$$

11-74 An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Analysis (a) We assume the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 280 \text{ K} \longrightarrow h_1 = 280.13 \text{ kJ/kg}$$

$$P_{r_1} = 1.0889$$

$$T_3 = 310 \text{ K} \longrightarrow h_3 = 310.24 \text{ kJ/kg}$$

$$P_{r_3} = 1.5546$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left(\frac{160}{35} \right) (1.0889) = 4.978 \longrightarrow T_{2s} = 431.5 \text{ K}$$

$$h_{2s} = 432.96 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{35}{160} \right) (1.5546) = 0.3401 \longrightarrow T_{4s} = 200.6 \text{ K}$$

$$h_{4s} = 200.57 \text{ kJ/kg}$$

Also,

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

$$= 310.24 - (0.85)(310.24 - 200.57)$$

$$= 217.02 \text{ kJ/kg}$$

Then the rate of refrigeration is

$$\dot{Q}_L = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.2 \text{ kg/s})(280.13 - 217.02) \text{ kJ/kg} = \mathbf{12.6 \text{ kW}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net,in}} = \dot{W}_{\text{comp,in}} - \dot{W}_{\text{turb,out}}$$

where

$$\dot{W}_{\text{comp,in}} = \dot{m}(h_2 - h_1) = \dot{m}(h_{2s} - h_1) / \eta_C$$

$$= (0.2 \text{ kg/s})[(432.96 - 280.13) \text{ kJ/kg}] / (0.80) = 38.21 \text{ kW}$$

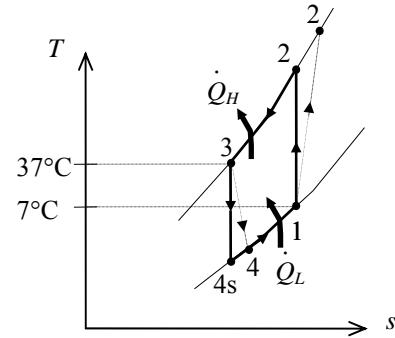

$$\dot{W}_{\text{turb,out}} = \dot{m}(h_3 - h_4) = (0.2 \text{ kg/s})(310.24 - 217.02) \text{ kJ/kg} = 18.64 \text{ kW}$$

Thus,

$$\dot{W}_{\text{net,in}} = 38.21 - 18.64 = \mathbf{19.6 \text{ kW}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{12.6 \text{ kW}}{19.6 \text{ kW}} = \mathbf{0.643}$$

11-75 Problem 11-74 is reconsidered. The effects of compressor and turbine isentropic efficiencies on the rate of refrigeration, the net power input, and the COP are to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

11-76 A gas refrigeration cycle with helium as the working fluid is considered. The minimum temperature in the cycle, the COP, and the mass flow rate of the helium are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Helium is an ideal gas with constant specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of helium are $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis (a) From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (263\text{K}) (3)^{0.667/1.667} = 408.2\text{K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (323\text{K}) \left(\frac{1}{3} \right)^{0.667/1.667} = 208.1\text{K}$$

and

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta_T (T_3 - T_{4s}) = 323 - (0.80)(323 - 208.1) = \mathbf{231.1 \text{ K}} = T_{\min}$$

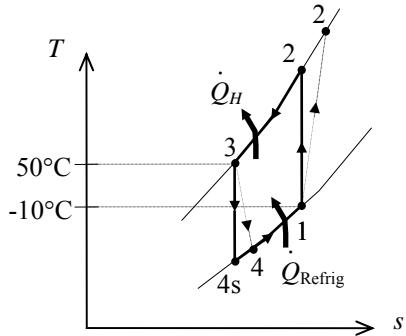

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 263 + (408.2 - 263) / (0.80) = 444.5 \text{ K}$$

(b) The COP of this gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{263 - 231.1}{(444.5 - 263) - (323 - 231.1)} = \mathbf{0.356} \end{aligned}$$

(c) The mass flow rate of helium is determined from

$$\dot{m} = \frac{\dot{Q}_{\text{refrig}}}{q_L} = \frac{\dot{Q}_{\text{refrig}}}{h_1 - h_4} = \frac{\dot{Q}_{\text{refrig}}}{c_p(T_1 - T_4)} = \frac{18 \text{ kJ/s}}{(5.1926 \text{ kJ/kg}\cdot\text{K})(263 - 231.1) \text{ K}} = \mathbf{0.109 \text{ kg/s}}$$

11-77E An ideal gas refrigeration cycle with air as the working fluid has a compression ratio of 4. The COP of the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

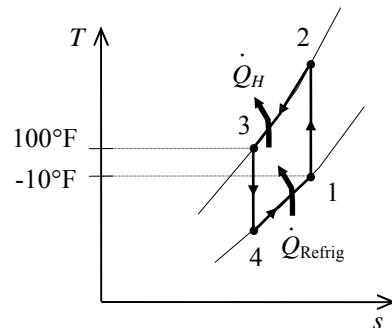

Analysis From the isentropic relations,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (450 \text{ R}) (4)^{0.4/1.4} = 668.7 \text{ R}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (560 \text{ R}) \left(\frac{1}{4} \right)^{0.4/1.4} = 376.8 \text{ R}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{450 - 376.8}{(668.7 - 450) - (560 - 376.8)} \\ &= \mathbf{2.06} \end{aligned}$$

11-78E An gas refrigeration cycle with air as the working fluid has a compression ratio of 4. The COP of the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are

$c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (450 \text{ R})(4)^{0.4/1.4} = 668.7 \text{ R}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (560 \text{ R}) \left(\frac{6 \text{ psia}}{19 \text{ psia}} \right)^{0.4/1.4} = 402.9 \text{ R}$$

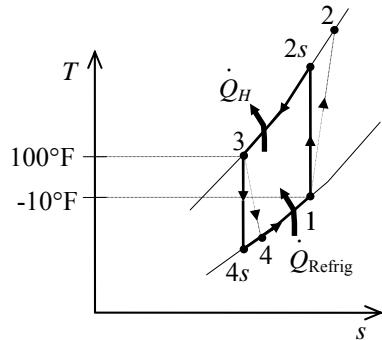

and

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta_T (T_3 - T_{4s}) = 560 - (0.94)(560 - 402.9) = 412.3 \text{ R}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 450 + (668.7 - 450) / (0.87) = 701.4 \text{ R}$$

The COP of this gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{450 - 412.3}{(701.4 - 450) - (560 - 412.3)} \\ &= \mathbf{0.364} \end{aligned}$$

11-79 An ideal gas refrigeration cycle with air as the working fluid is considered. The minimum pressure ratio for this system to operate properly is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air is an ideal gas with constant specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are

$$c_p = 1.005 \text{ kJ/kg}\cdot\text{K} \text{ and } k = 1.4 \text{ (Table A-2a).}$$

Analysis An energy balance on process 4-1 gives

$$q_{\text{Refrig}} = c_p (T_1 - T_4)$$

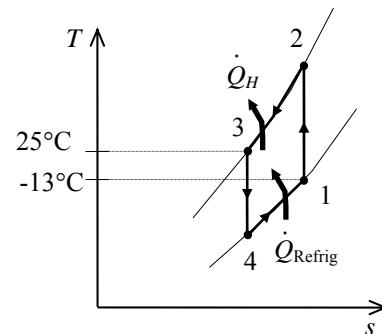

$$T_4 = T_1 - \frac{q_{\text{Refrig}}}{c_p} = 260 \text{ K} - \frac{36 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 224.2 \text{ K}$$

The minimum temperature at the turbine inlet would be the same as that to which the heat is rejected. That is,

$$T_3 = 298 \text{ K}$$

Then the minimum pressure ratio is determined from the isentropic relation to be

$$\frac{P_3}{P_4} = \left(\frac{T_3}{T_4} \right)^{k/(k-1)} = \left(\frac{298 \text{ K}}{224.2 \text{ K}} \right)^{1.4/0.4} = \mathbf{2.71}$$

11-80 A regenerative gas refrigeration cycle using air as the working fluid is considered. The effectiveness of the regenerator, the rate of heat removal from the refrigerated space, the COP of the cycle, and the refrigeration load and the COP if this system operated on the simple gas refrigeration cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (273.2 \text{ K}) (5)^{0.4/1.4} = 432.4 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.80 = \frac{432.4 - 273.2}{T_2 - 273.2} \rightarrow T_2 = 472.5 \text{ K}$$

The temperature at state 4 can be determined by solving the following two equations simultaneously:

$$T_{5s} = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = T_4 \left(\frac{1}{5} \right)^{0.4/1.4}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \rightarrow 0.85 = \frac{T_4 - 193.2}{T_4 - T_{5s}}$$

Using EES, we obtain $T_4 = 281.3 \text{ K}$.

An energy balance on the regenerator may be written as

$$\dot{m}c_p(T_3 - T_4) = \dot{m}c_p(T_1 - T_6) \rightarrow T_3 - T_4 = T_1 - T_6$$

or,

$$T_6 = T_1 - T_3 + T_4 = 273.2 - 308.2 + 281.3 = 246.3 \text{ K}$$

The effectiveness of the regenerator is

$$\varepsilon_{\text{regen}} = \frac{h_3 - h_4}{h_3 - h_6} = \frac{T_3 - T_4}{T_3 - T_6} = \frac{308.2 - 281.3}{308.2 - 246.3} = \mathbf{0.434}$$

(b) The refrigeration load is

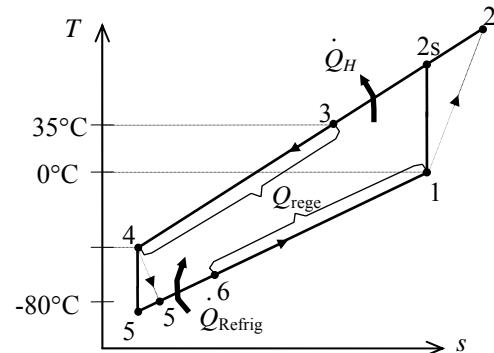

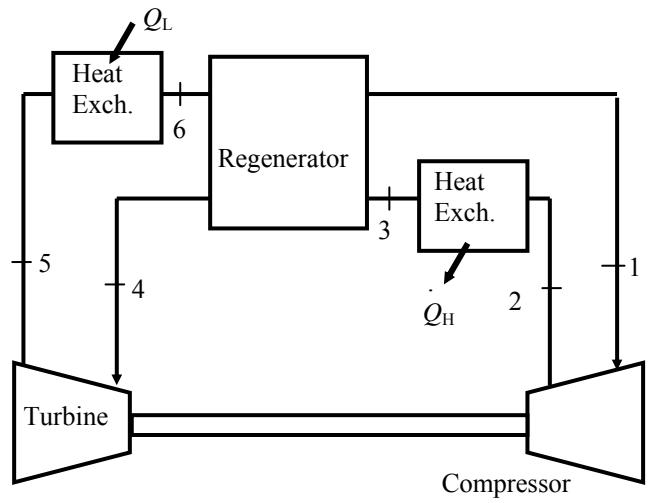

$$\dot{Q}_L = \dot{m}c_p(T_6 - T_5) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(246.3 - 193.2) \text{ K} = \mathbf{21.36 \text{ kW}}$$

(c) The turbine and compressor powers and the COP of the cycle are

$$\dot{W}_{C,\text{in}} = \dot{m}c_p(T_2 - T_1) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(472.5 - 273.2) \text{ K} = 80.13 \text{ kW}$$

$$\dot{W}_{T,\text{out}} = \dot{m}c_p(T_4 - T_5) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(281.3 - 193.2) \text{ K} = 35.43 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{\dot{Q}_L}{\dot{W}_{C,\text{in}} - \dot{W}_{T,\text{out}}} = \frac{21.36}{80.13 - 35.43} = \mathbf{0.478}$$

(d) The simple gas refrigeration cycle analysis is as follows:

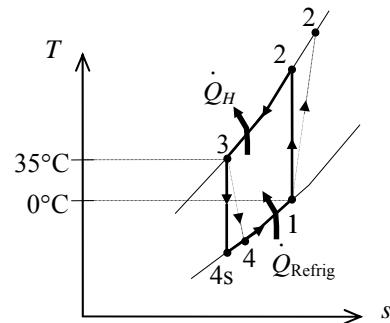

$$T_{4s} = T_3 \left(\frac{1}{r} \right)^{(k-1)/k} = (308.2 \text{ K}) \left(\frac{1}{5} \right)^{0.4/1.4} = 194.6 \text{ K}$$

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow 0.85 = \frac{308.2 - T_4}{308.2 - 194.6} \longrightarrow T_4 = 211.6 \text{ K}$$

$$\begin{aligned}\dot{Q}_L &= \dot{m}c_p(T_1 - T_4) \\ &= (0.4 \text{ kg/s})(1.005 \text{ kJ/kg.K})(273.2 - 211.6) \text{ kJ/kg} \\ &= \mathbf{24.74 \text{ kW}}\end{aligned}$$

$$\begin{aligned}\dot{W}_{\text{net,in}} &= \dot{m}c_p(T_2 - T_1) - \dot{m}c_p(T_3 - T_4) \\ &= (0.4 \text{ kg/s})(1.005 \text{ kJ/kg.K})[(472.5 - 273.2) - (308.2 - 211.6)] \text{ kJ/kg} \\ &= 41.32 \text{ kW}\end{aligned}$$

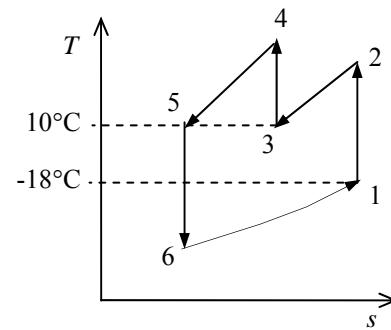

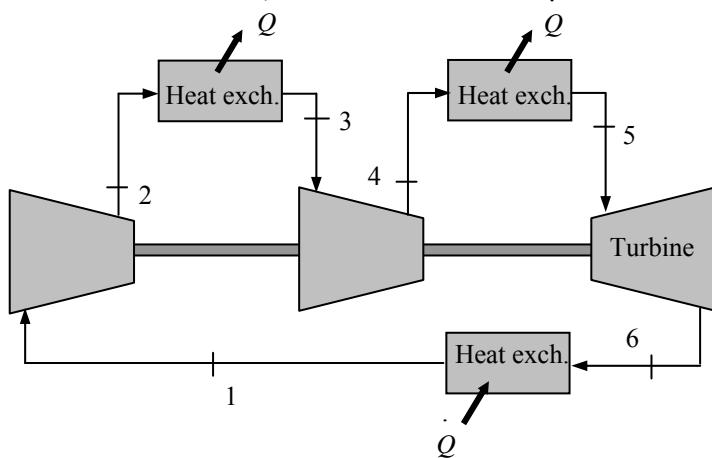

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{24.74}{41.32} = \mathbf{0.599}$$

11-81 An ideal gas refrigeration cycle with two stages of compression with intercooling using air as the working fluid is considered. The COP of this system and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis From the isentropic relations,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (255 \text{ K}) (4)^{0.4/1.4} = 378.9 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (283 \text{ K}) (4)^{0.4/1.4} = 420.5 \text{ K}$$

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (283 \text{ K}) \left(\frac{1}{16} \right)^{0.4/1.4} = 128.2 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_6}{(h_2 - h_1) + (h_4 - h_3) - (h_5 - h_6)} \\ &= \frac{T_1 - T_6}{(T_2 - T_1) + (T_4 - T_3) - (T_5 - T_6)} \\ &= \frac{255 - 128.2}{(378.9 - 255) + (420.5 - 283) - (283 - 128.2)} = \mathbf{1.19} \end{aligned}$$

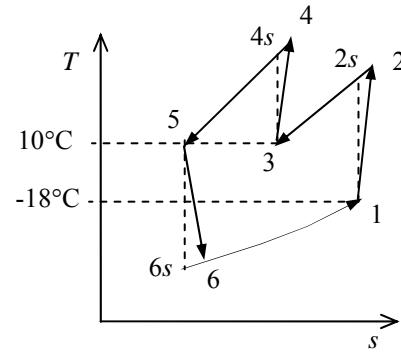

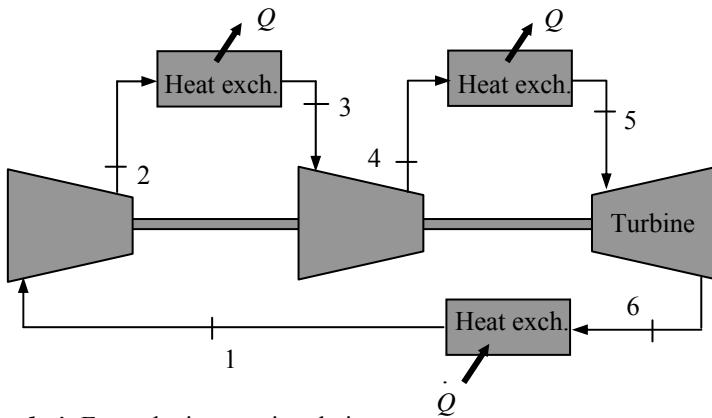

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_6) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_6)} = \frac{(75,000 / 3600) \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot\text{K})(255 - 128.2) \text{ K}} = \mathbf{0.163 \text{ kg/s}}$$

11-82 A gas refrigeration cycle with two stages of compression with intercooling using air as the working fluid is considered. The COP of this system and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (255 \text{ K}) (4)^{0.4/1.4} = 378.9 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (283 \text{ K}) (4)^{0.4/1.4} = 420.5 \text{ K}$$

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (283 \text{ K}) \left(\frac{1}{16} \right)^{0.4/1.4} = 128.2 \text{ K}$$

and

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 255 + (378.9 - 255) / 0.85 = 400.8 \text{ K}$$

$$\eta_C = \frac{h_{4s} - h_3}{h_4 - h_3} = \frac{T_{4s} - T_3}{T_4 - T_3} \longrightarrow T_4 = T_3 + (T_{4s} - T_3) / \eta_C = 283 + (420.5 - 283) / 0.85 = 444.8 \text{ K}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} = \frac{T_5 - T_6}{T_5 - T_{6s}} \longrightarrow T_6 = T_5 - \eta_T (T_5 - T_{6s}) = 283 - (0.95)(283 - 128.2) = 135.9 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_6}{(h_2 - h_1) + (h_4 - h_3) - (h_5 - h_6)} \\ &= \frac{T_1 - T_6}{(T_2 - T_1) + (T_4 - T_3) - (T_5 - T_6)} \\ &= \frac{255 - 135.9}{(400.8 - 255) + (444.8 - 283) - (283 - 135.9)} = \mathbf{0.742} \end{aligned}$$

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_6) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_6)} = \frac{(75,000 / 3600) \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot\text{K})(255 - 135.9) \text{ K}} = \mathbf{0.174 \text{ kg/s}}$$

11-83 A regenerative gas refrigeration cycle with argon as the working fluid is considered. To determine the COP, the minimum power input, the second-law efficiency, and the total exergy destruction in the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Properties The properties of argon are $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$.

Analysis (a) From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (243 \text{ K}) (5)^{0.667/1.667} = 462.7 \text{ K}$$

$$T_{5s} = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (235 \text{ K}) \left(\frac{1}{5} \right)^{0.667/1.667} = 123.4 \text{ K}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} = \frac{T_4 - T_5}{T_4 - T_{5s}}$$

$$\longrightarrow T_5 = T_4 - \eta_T (T_4 - T_{5s}) = 235 - (0.82)(235 - 123.4) = 143.5 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$\longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 243 + (462.7 - 243) / 0.82 = 510.9 \text{ K}$$

From an energy balance on the regenerator,

$$\dot{m}c_p(T_3 - T_4) = \dot{m}c_p(T_1 - T_6) \longrightarrow T_3 - T_4 = T_1 - T_6$$

or

$$T_6 = T_1 - T_3 + T_4 = 243 - 288 + 235 = 190 \text{ K}$$

$$\dot{Q}_L = \dot{m}c_p(T_6 - T_5) = (0.08 \text{ kg/s})(0.5203 \text{ kJ/kg}\cdot\text{K})(190 - 143.5) \text{ K} = \mathbf{1.935 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m}c_p[(T_2 - T_1) - (T_4 - T_5)] \\ &= (0.08 \text{ kg/s})(0.5203 \text{ kJ/kg}\cdot\text{K})[(510.9 - 243) - (235 - 143.5)] \text{ K} = 7.343 \text{ kW} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net}}} = \frac{1.935}{7.343} = \mathbf{0.2636}$$

(b) The exergy of the heat transferred from the low-temperature medium is

$$\dot{Ex}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(1.935 \text{ kW}) \left(1 - \frac{273}{228} \right) = 0.382 \text{ kW}$$

This is the minimum power input:

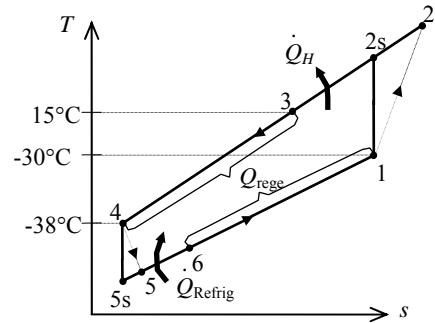

$$\dot{W}_{\min} = \dot{Ex}_{\dot{Q}_L} = \mathbf{0.382 \text{ kW}}$$

The second-law efficiency of the cycle is

$$\eta_{II} = \frac{\dot{Ex}_{\dot{Q}_L}}{\dot{W}_{\text{net}}} = \frac{0.382}{7.343} = 0.05202 = \mathbf{5.2\%}$$

The total exergy destruction in the cycle can be determined from

$$\dot{Ex}_{\text{dest,total}} = \dot{W}_{\text{net}} - \dot{Ex}_{\dot{Q}_L} = 7.343 - 0.382 = \mathbf{6.961 \text{ kW}}$$

Absorption Refrigeration Systems

11-84C In absorption refrigeration, water can be used as the refrigerant in air conditioning applications since the temperature of water never needs to fall below the freezing point.

11-85C Absorption refrigeration is the kind of refrigeration that involves the absorption of the refrigerant during part of the cycle. In absorption refrigeration cycles, the refrigerant is compressed in the liquid phase instead of in the vapor form.

11-86C The main advantage of absorption refrigeration is its being economical in the presence of an inexpensive heat source. Its disadvantages include being expensive, complex, and requiring an external heat source.

11-87C The fluid in the absorber is cooled to maximize the refrigerant content of the liquid; the fluid in the generator is heated to maximize the refrigerant content of the vapor.

11-88C The coefficient of performance of absorption refrigeration systems is defined as

$$\text{COP}_R = \frac{\text{desiredoutput}}{\text{requiredinput}} = \frac{Q_L}{Q_{\text{gen}} + W_{\text{pump,in}}} \approx \frac{Q_L}{Q_{\text{gen}}}$$

11-89C The rectifier separates the water from NH₃ and returns it to the generator. The regenerator transfers some heat from the water-rich solution leaving the generator to the NH₃-rich solution leaving the pump.

11-90 The COP of an absorption refrigeration system that operates at specified conditions is given. It is to be determined whether the given COP value is possible.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\text{max}} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{292 \text{ K}}{368 \text{ K}}\right) \left(\frac{273}{292 - 273}\right) = 2.97$$

which is smaller than 3.1. Thus the claim is **not possible**.

11-91 The conditions at which an absorption refrigeration system operates are specified. The maximum COP this absorption refrigeration system can have is to be determined.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{393 \text{ K}}\right) \left(\frac{273}{298 - 273}\right) = \mathbf{2.64}$$

11-92 The conditions at which an absorption refrigeration system operates are specified. The maximum rate at which this system can remove heat from the refrigerated space is to be determined.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{403 \text{ K}}\right) \left(\frac{243}{298 - 243}\right) = 1.15$$

Thus,

$$\dot{Q}_{L,\max} = \text{COP}_{R,\max} \dot{Q}_{\text{gen}} = (1.15)(5 \times 10^5 \text{ kJ/h}) = \mathbf{5.75 \times 10^5 \text{ kJ/h}}$$

11-93 A reversible absorption refrigerator consists of a reversible heat engine and a reversible refrigerator. The rate at which the steam condenses, the power input to the reversible refrigerator, and the second law efficiency of an actual chiller are to be determined.

Properties The enthalpy of vaporization of water at 150°C is $h_{fg} = 2113.8 \text{ kJ/kg}$ (Table A-4).

Analysis (a) The thermal efficiency of the reversible heat engine is

$$\eta_{\text{th,rev}} = 1 - \frac{T_0}{T_s} = 1 - \frac{(25 + 273.15) \text{ K}}{(150 + 273.15) \text{ K}} = 0.2954$$

The COP of the reversible refrigerator is

$$\text{COP}_{\text{R,rev}} = \frac{T_L}{T_0 - T_L} = \frac{(-15 + 273.15) \text{ K}}{(25 + 273.15) - (-15 + 273.15) \text{ K}} = 6.454$$

The COP of the reversible absorption refrigerator is

$$\text{COP}_{\text{abs,rev}} = \eta_{\text{th,rev}} \text{COP}_{\text{R,rev}} = (0.2954)(6.454) = 1.906$$

The heat input to the reversible heat engine is

$$\dot{Q}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_{\text{abs,rev}}} = \frac{70 \text{ kW}}{1.906} = 36.72 \text{ kW}$$

Then, the rate at which the steam condenses becomes

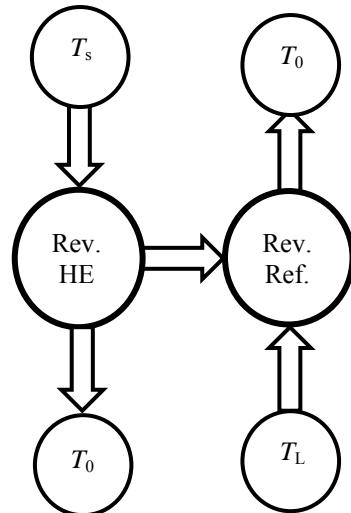

$$\dot{m}_s = \frac{\dot{Q}_{\text{in}}}{h_{fg}} = \frac{36.72 \text{ kJ/s}}{2113.8 \text{ kJ/kg}} = \mathbf{0.0174 \text{ kg/s}}$$

(b) The power input to the refrigerator is equal to the power output from the heat engine

$$\dot{W}_{\text{in,R}} = \dot{W}_{\text{out,HE}} = \eta_{\text{th,rev}} \dot{Q}_{\text{in}} = (0.2954)(36.72 \text{ kW}) = \mathbf{10.9 \text{ kW}}$$

(c) The second-law efficiency of an actual absorption chiller with a COP of 0.8 is

$$\eta_{\text{II}} = \frac{\text{COP}_{\text{actual}}}{\text{COP}_{\text{abs,rev}}} = \frac{0.8}{1.906} = 0.420 = \mathbf{42.0\%}$$

11-94E An ammonia-water absorption refrigeration cycle is considered. The rate of cooling, the COP, and the second-law efficiency of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Properties The properties of ammonia are as given in the problem statement. The specific heat of geothermal water is given to be 1.0 Btu/lbm·°F.

Analysis (a) The rate of cooling provided by the system is

$$\begin{aligned}\dot{Q}_L &= \dot{m}_R (h_1 - h_4) = (0.04 \text{ lbm/s})(619.2 - 190.9) \text{ Btu/lbm} \\ &= 17.13 \text{ Btu/s} = \mathbf{61,700 \text{ Btu/h}}\end{aligned}$$

(b) The rate of heat input to the generator is

$$\dot{Q}_{\text{gen}} = \dot{m}_{\text{geo}} c_p (T_{\text{geo,in}} - T_{\text{geo,out}}) = (0.55 \text{ lbm/s})(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(240 - 200)^\circ\text{F} = 22.0 \text{ Btu/s}$$

Then the COP becomes

$$\text{COP} = \frac{\dot{Q}_L}{\dot{Q}_{\text{gen}}} = \frac{17.13 \text{ Btu/s}}{22.0 \text{ Btu/s}} = \mathbf{0.779}$$

(c) The reversible COP of the system is

$$\text{COP}_{\text{abs,rev}} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L} \right) = \left(1 - \frac{(70 + 460)}{(220 + 460)}\right) \left(\frac{(25 + 460)}{70 - 25} \right) = 2.38$$

The temperature of the heat source is taken as the average temperature of the geothermal water: $(240+200)/2=220^\circ\text{F}$. Then the second-law efficiency becomes

$$\eta_{II} = \frac{\text{COP}}{\text{COP}_{\text{abs,rev}}} = \frac{0.779}{2.38} = 0.328 = \mathbf{32.8\%}$$

Special Topic: Thermoelectric Power Generation and Refrigeration Systems

11-95C The circuit that incorporates both thermal and electrical effects is called a thermoelectric circuit.

11-96C When two wires made from different metals joined at both ends (junctions) forming a closed circuit and one of the joints is heated, a current flows continuously in the circuit. This is called the Seebeck effect. When a small current is passed through the junction of two dissimilar wires, the junction is cooled. This is called the Peltier effect.

11-97C No.

11-98C No.

11-99C Yes.

11-100C When a thermoelectric circuit is broken, the current will cease to flow, and we can measure the voltage generated in the circuit by a voltmeter. The voltage generated is a function of the temperature difference, and the temperature can be measured by simply measuring voltages.

11-101C The performance of thermoelectric refrigerators improves considerably when semiconductors are used instead of metals.

11-102C The efficiency of a thermoelectric generator is limited by the Carnot efficiency because a thermoelectric generator fits into the definition of a heat engine with electrons serving as the working fluid.

11-103E A thermoelectric generator that operates at specified conditions is considered. The maximum thermal efficiency this thermoelectric generator can have is to be determined.

Analysis The maximum thermal efficiency of this thermoelectric generator is the Carnot efficiency,

$$\eta_{\text{th,max}} = \eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{550\text{R}}{800\text{R}} = 31.3\%$$

11-104 A thermoelectric refrigerator that operates at specified conditions is considered. The maximum COP this thermoelectric refrigerator can have and the minimum required power input are to be determined.

Analysis The maximum COP of this thermoelectric refrigerator is the COP of a Carnot refrigerator operating between the same temperature limits,

$$\text{COP}_{\max} = \text{COP}_{R,\text{Carnot}} = \frac{1}{(T_H/T_L) - 1} = \frac{1}{(293\text{ K})/(268\text{ K}) - 1} = \mathbf{10.72}$$

Thus,

$$\dot{W}_{\text{in},\min} = \frac{\dot{Q}_L}{\text{COP}_{\max}} = \frac{130\text{ W}}{10.72} = \mathbf{12.1\text{ W}}$$

11-105 A thermoelectric cooler that operates at specified conditions with a given COP is considered. The required power input to the thermoelectric cooler is to be determined.

Analysis The required power input is determined from the definition of COP_R,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} \quad \longrightarrow \quad \dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_R} = \frac{180\text{ W}}{0.15} = \mathbf{1200\text{ W}}$$

11-106E A thermoelectric cooler that operates at specified conditions with a given COP is considered. The rate of heat removal is to be determined.

Analysis The required power input is determined from the definition of COP_R,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} \longrightarrow \dot{Q}_L = \text{COP}_R \dot{W}_{\text{in}} = (0.18)(1.8\text{ hp}) \left(\frac{42.41\text{ Btu/min}}{1\text{ hp}} \right) = \mathbf{13.7\text{ Btu/min}}$$

11-107 A thermoelectric refrigerator powered by a car battery cools 9 canned drinks in 12 h. The average COP of this refrigerator is to be determined.

Assumptions Heat transfer through the walls of the refrigerator is negligible.

Properties The properties of canned drinks are the same as those of water at room temperature, $\rho = 1 \text{ kg/L}$ and $c_p = 4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$ (Table A-3).

Analysis The cooling rate of the refrigerator is simply the rate of decrease of the energy of the canned drinks,

$$m = \rho V = 9 \times (1 \text{ kg/L})(0.350 \text{ L}) = 3.15 \text{ kg}$$

$$Q_{\text{cooling}} = mc\Delta T = (3.15 \text{ kg})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(25 - 3)^\circ\text{C} = 290 \text{ kJ}$$

$$\dot{Q}_{\text{cooling}} = \frac{Q_{\text{cooling}}}{\Delta t} = \frac{290 \text{ kJ}}{12 \times 3600 \text{ s}} = 0.00671 \text{ kW} = 6.71 \text{ W}$$

The electric power consumed by the refrigerator is

$$\dot{W}_{\text{in}} = \mathbf{VI} = (12 \text{ V})(3 \text{ A}) = 36 \text{ W}$$

Then the COP of the refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{in}}} = \frac{6.71 \text{ W}}{36 \text{ W}} = \mathbf{0.186} \approx 0.20$$

11-108E A thermoelectric cooler is said to cool a 12-oz drink or to heat a cup of coffee in about 15 min. The average rate of heat removal from the drink, the average rate of heat supply to the coffee, and the electric power drawn from the battery of the car are to be determined.

Assumptions Heat transfer through the walls of the refrigerator is negligible.

Properties The properties of canned drinks are the same as those of water at room temperature, $c_p = 1.0 \text{ Btu/lbm} \cdot ^\circ\text{F}$ (Table A-3E).

Analysis (a) The average cooling rate of the refrigerator is simply the rate of decrease of the energy content of the canned drinks,

$$Q_{\text{cooling}} = mc_p\Delta T = (0.771 \text{ lbm})(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(78 - 38)^\circ\text{F} = 30.84 \text{ Btu}$$

$$\dot{Q}_{\text{cooling}} = \frac{Q_{\text{cooling}}}{\Delta t} = \frac{30.84 \text{ Btu}}{15 \times 60 \text{ s}} \left(\frac{1055 \text{ J}}{1 \text{ Btu}} \right) = \mathbf{36.2 \text{ W}}$$

(b) The average heating rate of the refrigerator is simply the rate of increase of the energy content of the canned drinks,

$$Q_{\text{heating}} = mc_p\Delta T = (0.771 \text{ lbm})(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(130 - 75)^\circ\text{F} = 42.4 \text{ Btu}$$

$$\dot{Q}_{\text{heating}} = \frac{Q_{\text{heating}}}{\Delta t} = \frac{42.4 \text{ Btu}}{15 \times 60 \text{ s}} \left(\frac{1055 \text{ J}}{1 \text{ Btu}} \right) = \mathbf{49.7 \text{ W}}$$

(c) The electric power drawn from the car battery during cooling and heating is

$$\dot{W}_{\text{in,cooling}} = \frac{\dot{Q}_{\text{cooling}}}{\text{COP}_{\text{cooling}}} = \frac{36.2 \text{ W}}{0.2} = \mathbf{181 \text{ W}}$$

$$\text{COP}_{\text{heating}} = \text{COP}_{\text{cooling}} + 1 = 0.2 + 1 = 1.2$$

$$\dot{W}_{\text{in,heating}} = \frac{\dot{Q}_{\text{heating}}}{\text{COP}_{\text{heating}}} = \frac{49.7 \text{ W}}{1.2} = \mathbf{41.4 \text{ W}}$$

11-109 The maximum power a thermoelectric generator can produce is to be determined.

Analysis The maximum thermal efficiency this thermoelectric generator can have is

$$\eta_{\text{th,max}} = 1 - \frac{T_L}{T_H} = 1 - \frac{295 \text{ K}}{363 \text{ K}} = 0.1873$$

Thus,

$$\dot{W}_{\text{out,max}} = \eta_{\text{th,max}} \dot{Q}_{\text{in}} = (0.1873)(7 \times 10^6 \text{ kJ/h}) = 1.31 \times 10^6 \text{ kJ/h} = \mathbf{364 \text{ kW}}$$

Review Problems

11-110 A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP, the condenser and evaporator pressures, and the net work input are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) The COP of this refrigeration cycle is determined from

$$\text{COP}_{\text{R,C}} = \frac{1}{(T_H/T_L) - 1} = \frac{1}{(303\text{ K})/(253\text{ K}) - 1} = \mathbf{5.06}$$

(b) The condenser and evaporative pressures are (Table A-11)

$$P_{\text{evap}} = P_{\text{sat}@-20^\circ\text{C}} = \mathbf{132.82\text{ kPa}}$$

$$P_{\text{cond}} = P_{\text{sat}@30^\circ\text{C}} = \mathbf{770.64\text{ kPa}}$$

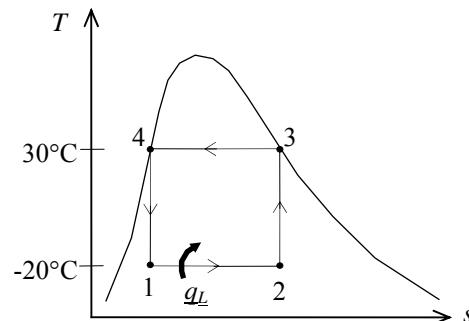

(c) The net work input is determined from

$$h_1 = (h_f + x_1 h_{fg})_{@-20^\circ\text{C}} = 25.49 + (0.15)(212.91) = 57.43 \text{ kJ/kg}$$

$$h_2 = (h_f + x_2 h_{fg})_{@-20^\circ\text{C}} = 25.49 + (0.80)(212.91) = 195.82 \text{ kJ/kg}$$

$$q_L = h_2 - h_1 = 195.82 - 57.43 = 138.4 \text{ kJ/kg}$$

$$w_{\text{net,in}} = \frac{q_L}{\text{COP}_R} = \frac{138.4 \text{ kJ/kg}}{5.06} = \mathbf{27.35 \text{ kJ/kg}}$$

11-111 A room is cooled adequately by a 5000 Btu/h window air-conditioning unit. The rate of heat gain of the room when the air-conditioner is running continuously is to be determined.

Assumptions 1 The heat gain includes heat transfer through the walls and the roof, infiltration heat gain, solar heat gain, internal heat gain, etc. **2** Steady operating conditions exist.

Analysis The rate of heat gain of the room in steady operation is simply equal to the cooling rate of the air-conditioning system,

$$\dot{Q}_{\text{heat gain}} = \dot{Q}_{\text{cooling}} = \mathbf{5,000 \text{ Btu/h}}$$

11-112 A heat pump water heater has a COP of 3.4 and consumes 6 kW when running. It is to be determined if this heat pump can be used to meet the cooling needs of a room by absorbing heat from it.

Assumptions The COP of the heat pump remains constant whether heat is absorbed from the outdoor air or room air.

Analysis The COP of the heat pump is given to be 3.4. Then the COP of the air-conditioning system becomes

$$\text{COP}_{\text{air-cond}} = \text{COP}_{\text{heat pump}} - 1 = 3.4 - 1 = 2.4$$

Then the rate of cooling (heat absorption from the air) becomes

$$\dot{Q}_{\text{cooling}} = \text{COP}_{\text{air-cond}} \dot{W}_{\text{in}} = (3.4)(6 \text{ kW}) = 20.4 \text{ kW} = 51,840 \text{ kJ/h}$$

since 1 kW = 3600 kJ/h. We conclude that this heat pump **can meet** the cooling needs of the room since its cooling rate is greater than the rate of heat gain of the room.

11-113 A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid is used to heat a house. The rate of heat supply to the house, the volume flow rate of the refrigerant at the compressor inlet, and the COP of this heat pump are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\begin{aligned} P_1 = 200 \text{ kPa} & \left. \begin{aligned} h_1 &= h_g @ 200 \text{ kPa} = 244.46 \text{ kJ/kg} \\ s_1 &= s_g @ 200 \text{ kPa} = 0.93773 \text{ kJ/kg} \cdot \text{K} \\ v_1 &= v_g @ 200 \text{ kPa} = 0.099867 \text{ m}^3/\text{kg} \end{aligned} \right\} \\ \text{sat. vapor} \end{aligned}$$

$$\begin{aligned} P_2 = 0.9 \text{ MPa} & \left. \begin{aligned} h_2 &= 275.75 \text{ kJ/kg} \\ s_2 &= s_1 \end{aligned} \right\} \\ \text{sat. liquid} \end{aligned}$$

$$\begin{aligned} P_3 = 0.9 \text{ MPa} & \left. \begin{aligned} h_3 &= h_f @ 0.9 \text{ MPa} = 101.61 \text{ kJ/kg} \\ \text{sat. liquid} \end{aligned} \right\} \end{aligned}$$

$$h_4 \cong h_3 = 101.61 \text{ kJ/kg} \quad (\text{throttling})$$

The rate of heat supply to the house is determined from

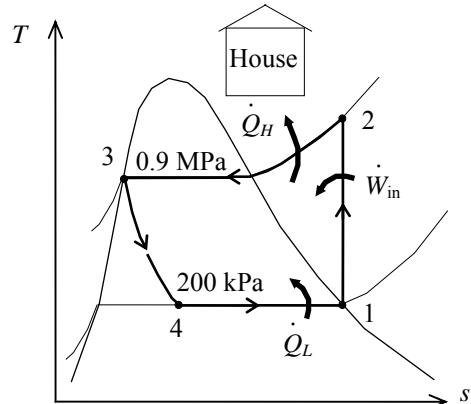

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.32 \text{ kg/s})(275.75 - 101.61) \text{ kJ/kg} = \mathbf{55.73 \text{ kW}}$$

(b) The volume flow rate of the refrigerant at the compressor inlet is

$$\dot{V}_1 = \dot{m}v_1 = (0.32 \text{ kg/s})(0.099867 \text{ m}^3/\text{kg}) = \mathbf{0.0320 \text{ m}^3/\text{s}}$$

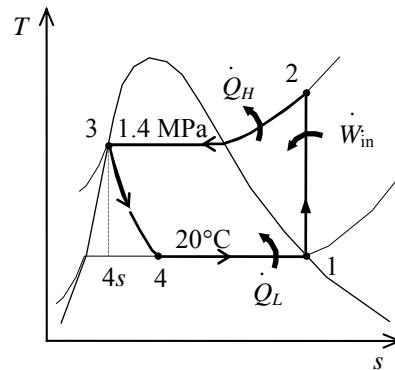

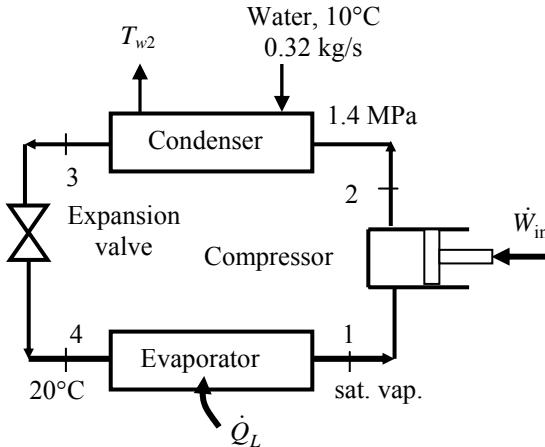

(c) The COP of this heat pump is determined from

$$\text{COP}_R = \frac{q_L}{w_{in}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{275.75 - 101.61}{275.75 - 244.46} = \mathbf{5.57}$$

11-114 A ground-coupled heat pump that operates on the vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The hardware and the *T-s* diagram for this air conditioner are to be sketched. The exit temperature of the water in the condenser and the COP are to be determined.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

(b) The properties as given in the problem statement are

$$h_4 = h_3 = h_f @ 1400 \text{ kPa} = 127.2 \text{ kJ/kg}$$

$$h_1 = h_g @ 20^\circ\text{C} = 261.6 \text{ kJ/kg}.$$

The rate of heat transfer in the condenser is determined from

$$\begin{aligned}\dot{Q}_H - \dot{Q}_L &= \frac{\dot{Q}_L}{\text{COP}_R} = \dot{W}_{\text{in}} \\ \dot{Q}_H &= \dot{Q}_L \left(1 + \frac{1}{\text{COP}_R}\right) = (18 \text{ kW}) \left(1 + \frac{1}{6}\right) = 21 \text{ kW}\end{aligned}$$

An energy balance on the condenser gives

$$\begin{aligned}\dot{Q}_H &= \dot{m}(h_2 - h_3) = \dot{m}_w c_{pw}(T_{2w} - T_{1w}) \\ T_{2w} &= T_{1w} + \frac{\dot{Q}_H}{\dot{m}_w c_{pw}} = 10^\circ\text{C} + \frac{21 \text{ kW}}{(0.32 \text{ kg/s})(4.18 \text{ kJ/kg}^\circ\text{C})} = 25.7^\circ\text{C}\end{aligned}$$

(c) The COP of the heat pump is

$$\text{COP}_{\text{HP}} = \frac{\dot{Q}_H}{\dot{Q}_H - \dot{Q}_L} = \frac{21 \text{ kW}}{21 \text{ kW} - 18 \text{ kW}} = 7$$

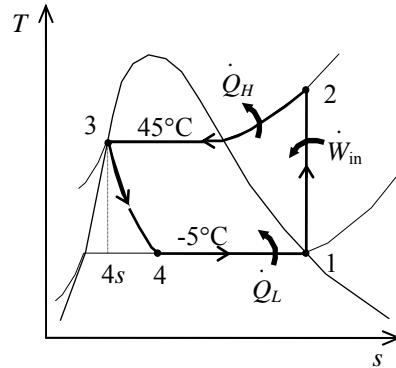

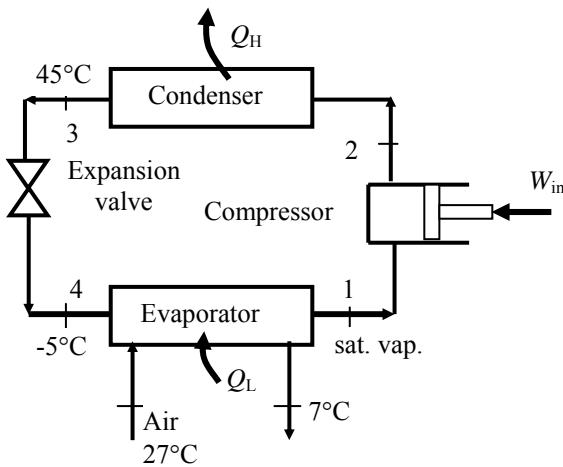

It may also be determined from

$$\text{COP}_{\text{HP}} = \text{COP}_R + 1 = 6 + 1 = 7$$

11-115 An ideal vapor-compression refrigeration cycle with refrigerant-22 as the working fluid is considered. The evaporator is located inside the air handler of building. The hardware and the T-s diagram for this heat pump application are to be sketched. The COP of the unit and the ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant-22 data from the problem statement,

$$\left. \begin{array}{l} T_1 = -5^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_1 = h_g @ -5^\circ\text{C} = 248.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} s_1 = s_g @ -5^\circ\text{C} \\ s_2 = s_1 \end{array} \right\} h_2 = 283.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1728 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1728 \text{ kPa} = 101 \text{ kJ/kg}$$

$$h_4 \equiv h_3 = 101 \text{ kJ/kg} \quad (\text{throttling})$$

(b) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{in}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{248.1 - 101}{283.7 - 248.1} = \mathbf{4.13}$$

(c) An energy balance on the evaporator gives

$$\dot{Q}_L = \dot{m}_R (h_1 - h_4) = \dot{m}_a c_p \Delta T = \frac{\dot{V}_a}{\nu_a} c_p \Delta T$$

Rearranging, we obtain the ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler

$$\begin{aligned} \frac{\dot{V}_a}{\dot{m}_R} &= \frac{h_1 - h_4}{(1/\nu)c_p \Delta T} = \frac{(248.1 - 101) \text{ kJ/kg}}{(1/0.8323 \text{ m}^3/\text{kg})(1.005 \text{ kJ/kg}\cdot\text{K})(20 \text{ K})} \\ &= 6.091 (\text{m}^3 \text{ air/s}) / (\text{kg R22/s}) \\ &= \mathbf{365 (\text{m}^3 \text{ air/min}) / (\text{kg R22/s})} \end{aligned}$$

Note that the specific volume of air is obtained from ideal gas equation taking the pressure of air to be 100 kPa (given) and using the average temperature of air ($17^\circ\text{C} = 290 \text{ K}$) to be $0.8323 \text{ m}^3/\text{kg}$.

11-116 An air conditioner operates on the vapor-compression refrigeration cycle. The rate of cooling provided to the space, the COP, the isentropic efficiency and the exergetic efficiency of the compressor, the exergy destruction in each component of the cycle, the total exergy destruction, the minimum power input, and the second-law efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11 through A-13)

$$T_{\text{sat}@180 \text{ kPa}} = -12.7^\circ\text{C}$$

$$\begin{aligned} P_1 &= 180 \text{ kPa} & h_1 &= 245.14 \text{ kJ/kg} \\ T_1 &= -12.7 + 2.7 = 10^\circ\text{C} & s_1 &= 0.9483 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} P_2 &= 1200 \text{ kPa} & h_{2s} &= 285.32 \text{ kJ/kg} \\ s_1 &= s_1 & s_2 &= 0.9614 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

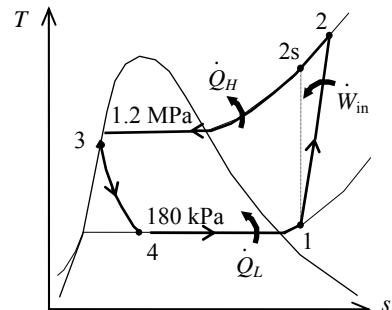

$$\begin{aligned} P_2 &= 1200 \text{ kPa} & h_2 &= 289.64 \text{ kJ/kg} \\ T_2 &= 60^\circ\text{C} & s_2 &= 0.9614 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$T_{\text{sat}@1200 \text{ kPa}} = 46.3^\circ\text{C}$$

$$\begin{aligned} P_3 &= 1200 \text{ kPa} & h_3 &\equiv h_{f@40^\circ\text{C}} = 108.26 \text{ kJ/kg} \\ T_3 &= 46.3 - 6.3 = 40^\circ\text{C} & s_3 &\equiv s_{f@40^\circ\text{C}} = 0.3948 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$h_4 = h_3 = 108.26 \text{ kJ/kg}$$

$$\begin{aligned} P_4 &= 180 \text{ kPa} & s_4 &= 0.4228 \text{ kJ/kg}\cdot\text{K} \\ h_4 &= 108.26 \text{ kJ/kg} & s_4 &= 0.4228 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

The cooling load and the COP are

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.06 \text{ kg/s})(245.14 - 108.26) \text{ kJ/kg} = 8.213 \text{ kW}$$

$$= (8.213 \text{ kW}) \left(\frac{3412 \text{ Btu/h}}{1 \text{ kW}} \right) = \mathbf{28,020 \text{ Btu/h}}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.06 \text{ kg/s})(289.64 - 108.26) \text{ kJ/kg} = 10.88 \text{ kW}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.06 \text{ kg/s})(289.64 - 245.14) \text{ kJ/kg} = 2.670 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{8.213 \text{ kW}}{2.670 \text{ kW}} = \mathbf{3.076}$$

(b) The isentropic efficiency of the compressor is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{285.32 - 245.14}{289.64 - 245.14} = 0.9029 = \mathbf{90.3\%}$$

The reversible power and the exergy efficiency for the compressor are

$$\begin{aligned} \dot{W}_{\text{rev}} &= \dot{m}[(h_2 - h_1) - T_0(s_2 - s_1)] \\ &= (0.06 \text{ kg/s})[(289.64 - 245.14) \text{ kJ/kg} - (310 \text{ K})(0.9614 - 0.9483) \text{ kJ/kg}\cdot\text{K}] \\ &= 2.428 \text{ kW} \end{aligned}$$

$$\eta_{ex,C} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_{\text{in}}} = \frac{2.428 \text{ kW}}{2.670 \text{ kW}} = 0.9091 = \mathbf{90.9\%}$$

(c) The exergy destruction in each component of the cycle is determined as follows

Compressor:

$$\dot{S}_{\text{gen},1-2} = \dot{m}(s_2 - s_1) = (0.06 \text{ kg/s})(0.9614 - 0.9483) \text{ kJ/kg}\cdot\text{K} = 0.0007827 \text{ kW/K}$$

$$\dot{Ex}_{\text{dest},1-2} = T_0 \dot{S}_{\text{gen},1-2} = (310 \text{ K})(0.0007827 \text{ kW/K}) = \mathbf{0.2426 \text{ kW}}$$

Condenser:

$$\dot{S}_{\text{gen},2-3} = \dot{m}(s_3 - s_2) + \frac{\dot{Q}_H}{T_H} = (0.06 \text{ kg/s})(0.3948 - 0.9614) \text{ kJ/kg} \cdot \text{K} + \frac{10.88 \text{ kW}}{310 \text{ K}} = 0.001114 \text{ kW/K}$$

$$\dot{Ex}_{\text{dest},2-3} = T_0 \dot{S}_{\text{gen},2-3} = (310 \text{ K})(0.001114 \text{ kJ/kg} \cdot \text{K}) = \mathbf{0.3452 \text{ kW}}$$

Expansion valve:

$$\dot{S}_{\text{gen},3-4} = \dot{m}(s_4 - s_3) = (0.06 \text{ kg/s})(0.4228 - 0.3948) \text{ kJ/kg} \cdot \text{K} = 0.001678 \text{ kW/K}$$

$$\dot{Ex}_{\text{dest},3-4} = T_0 \dot{S}_{\text{gen},3-4} = (310 \text{ K})(0.001678 \text{ kJ/kg} \cdot \text{K}) = \mathbf{0.5203 \text{ kJ/kg}}$$

Evaporator:

$$\dot{S}_{\text{gen},4-1} = \dot{m}(s_1 - s_4) - \frac{\dot{Q}_L}{T_L} = (0.06 \text{ kg/s})(0.9483 - 0.4228) \text{ kJ/kg} \cdot \text{K} - \frac{8.213 \text{ kW}}{294 \text{ K}} = 0.003597 \text{ kW/K}$$

$$\dot{Ex}_{\text{dest},4-1} = T_0 \dot{S}_{\text{gen},4-1} = (310 \text{ K})(0.003597 \text{ kJ/kg} \cdot \text{K}) = \mathbf{1.115 \text{ kW}}$$

The total exergy destruction can be determined by adding exergy destructions in each component:

$$\begin{aligned}\dot{Ex}_{\text{dest},\text{total}} &= \dot{Ex}_{\text{dest},1-2} + \dot{Ex}_{\text{dest},2-3} + \dot{Ex}_{\text{dest},3-4} + \dot{Ex}_{\text{dest},4-1} \\ &= 0.2426 + 0.3452 + 0.5203 + 1.115 \\ &= \mathbf{2.223 \text{ kW}}\end{aligned}$$

(d) The exergy of the heat transferred from the low-temperature medium is

$$\dot{Ex}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(8.213 \text{ kW}) \left(1 - \frac{310}{294} \right) = 0.4470 \text{ kW}$$

This is the minimum power input to the cycle:

$$\dot{W}_{\text{in,min}} = \dot{Ex}_{\dot{Q}_L} = \mathbf{0.4470 \text{ kW}}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{in,min}}}{\dot{W}_{\text{in}}} = \frac{0.4470}{2.670} = 0.1674 = \mathbf{16.7\%}$$

The total exergy destruction in the cycle can also be determined from

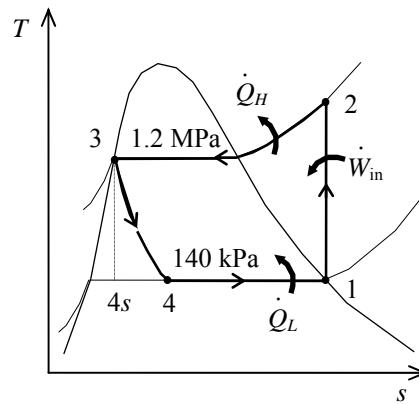

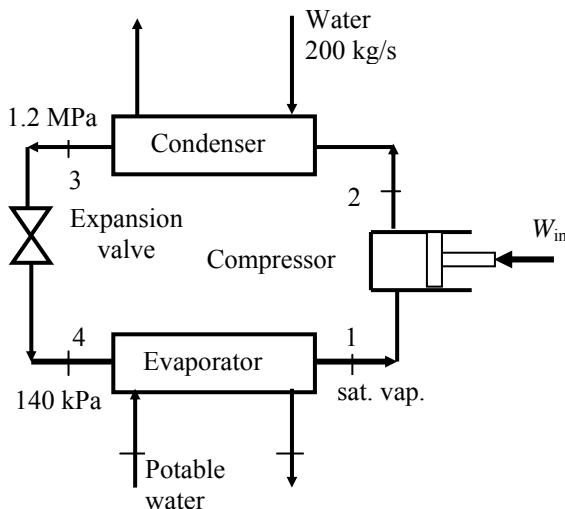

$$\dot{Ex}_{\text{dest},\text{total}} = \dot{W}_{\text{in}} - \dot{Ex}_{\dot{Q}_L} = 2.670 - 0.4470 = 2.223 \text{ kW}$$

The result is the same as expected.

11-117 An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. Cooling water flows through the water jacket surrounding the condenser. To produce ice, potable water is supplied to the chiller section of the refrigeration cycle. The hardware and the T-s diagram for this refrigerant-ice making system are to be sketched. The mass flow rates of the refrigerant and the potable water are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant-134a tables,

$$\left. \begin{array}{l} T_1 = 140 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \quad \left. \begin{array}{l} h_1 = h_g @ 140 \text{ kPa} = 239.16 \text{ kJ/kg} \\ s_1 = s_g @ 140 \text{ kPa} = 0.94456 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} \quad h_2 = 284.07 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1200 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} \quad h_3 = h_f @ 1200 \text{ kPa} = 117.77 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 117.77 \text{ kJ/kg} \quad (\text{throttling})$$

(b) An energy balance on the condenser gives

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = \dot{m}_w c_p \Delta T$$

Solving for the mass flow rate of the refrigerant

$$\dot{m}_R = \frac{\dot{m}_w c_p \Delta T}{h_2 - h_3} = \frac{(200 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot\text{K})(10 \text{ K})}{(284.07 - 117.77) \text{ kJ/kg}} = \mathbf{50.3 \text{ kg/s}}$$

(c) An energy balance on the evaporator gives

$$\dot{Q}_L = \dot{m}_R (h_1 - h_4) = \dot{m}_w h_{if}$$

Solving for the mass flow rate of the potable water

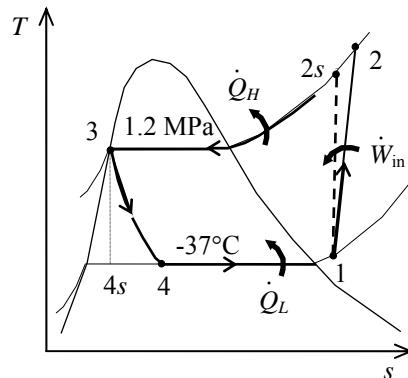

$$\dot{m}_w = \frac{\dot{m}_R (h_1 - h_4)}{h_{if}} = \frac{(50.3 \text{ kg/s})(239.16 - 117.77) \text{ kJ/kg}}{333 \text{ kJ/kg}} = \mathbf{18.3 \text{ kg/s}}$$

11-118 A refrigerator operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy loss is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In this cycle, the refrigerant leaves the condenser as saturated liquid at the condenser pressure. The compression process is not isentropic. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\begin{aligned} P_1 &= P_{\text{sat} @ -37^\circ\text{C}} = 60 \text{ kPa} & h_1 &= 233.09 \text{ kJ/kg} \\ T_1 &= -37 + 7 = -30^\circ\text{C} & s_1 &= 0.9867 \text{ kJ/kg}\cdot\text{K} \\ P_2 &= 1.2 \text{ MPa} & h_{2s} &= 298.11 \text{ kJ/kg} \\ s_2 &= s_1 & & \\ P_3 &= 1.2 \text{ MPa} & h_3 &= h_f @ 1.2 \text{ MPa} = 117.77 \text{ kJ/kg} \\ \text{sat. liquid} & & s_3 &= s_f @ 1.2 \text{ MPa} = 0.42441 \text{ kJ/kg}\cdot\text{K} \\ h_4 &\cong h_3 = 117.77 \text{ kJ/kg} \quad (\text{throttling}) & & \\ T_4 &= -37^\circ\text{C} & x_4 &= 0.5089 \\ h_4 &= 117.77 \text{ kJ/kg} & s_4 &= 0.4988 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 233.09 + \frac{298.11 - 233.09}{0.90} = 305.33 \text{ kJ/kg}$$

and $P_2 = 1.2 \text{ MPa}$

$$h_2 = 305.33 \text{ Btu/lbm} \quad \left. \right\} s_2 = 1.0075 \text{ kJ/kg}\cdot\text{K}$$

The heat added in the evaporator and that rejected in the condenser are

$$q_L = h_1 - h_4 = (233.09 - 117.77) \text{ kJ/kg} = 115.32 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = (305.33 - 117.77) \text{ kJ/kg} = 187.56 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed},12} = T_0 (s_2 - s_1) = (303 \text{ K})(1.0075 - 0.9867) \text{ kJ/kg}\cdot\text{K} = 6.37 \text{ kJ/kg}$$

$$x_{\text{destroyed},23} = T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) = (303 \text{ K}) \left(0.42441 - 1.0075 + \frac{187.56 \text{ kJ/kg}}{303 \text{ K}} \right) = 10.88 \text{ kJ/kg}$$

$$x_{\text{destroyed},34} = T_0 (s_4 - s_3) = (303 \text{ K})(0.4988 - 0.42441) \text{ kJ/kg}\cdot\text{K} = 22.54 \text{ kJ/kg}$$

$$x_{\text{destroyed},41} = T_0 \left(s_1 - s_4 - \frac{q_L}{T_L} \right) = (303 \text{ K}) \left(0.9867 - 0.4988 - \frac{115.3 \text{ kJ/kg}}{(-34 + 273) \text{ K}} \right) = 1.66 \text{ kJ/kg}$$

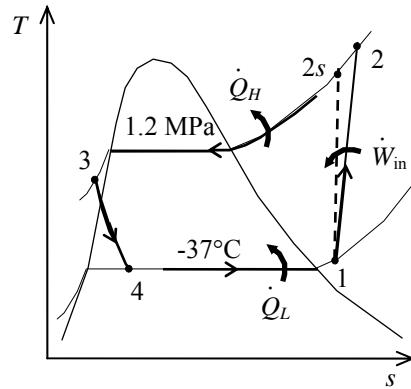

The greatest exergy destruction occurs in the expansion valve. Note that heat is absorbed from fruits at -34°C (239 K) and rejected to the ambient air at 30°C (303 K), which is also taken as the dead state temperature. Alternatively, one may use the standard 25°C (298 K) as the dead state temperature, and perform the calculations accordingly.

11-119 A refrigerator operating on a vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy loss is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\begin{aligned} P_1 &= P_{\text{sat} @ -37^\circ\text{C}} = 60 \text{ kPa} & h_1 &= 233.09 \text{ kJ/kg} \\ T_1 &= -37 + 7 = -30^\circ\text{C} & s_1 &= 0.9867 \text{ kJ/kg} \cdot \text{K} \\ P_2 &= 1.2 \text{ MPa} & h_{2s} &= 298.11 \text{ kJ/kg} \\ s_2 &= s_1 & \\ P_3 &= 1.2 \text{ MPa} & h_3 &\cong h_f @ 40^\circ\text{C} = 108.26 \text{ kJ/kg} \\ T_3 &= T_{\text{sat} @ 1.2 \text{ MPa}} - 6.3 & s_3 &\cong s_f @ 40^\circ\text{C} = 0.39486 \text{ kJ/kg} \cdot \text{K} \\ &= 46.3 - 6.3 = 40^\circ\text{C} & \\ h_4 &\cong h_3 = 108.26 \text{ kJ/kg} \quad (\text{throttling}) & \\ T_4 &= -37^\circ\text{C} & x_4 &= 0.4665 \\ h_4 &= 108.26 \text{ kJ/kg} & s_4 &= 0.4585 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The actual enthalpy at the compressor exit is determined by using the compressor efficiency:

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} = 233.09 + \frac{298.11 - 233.09}{0.90} = 305.33 \text{ kJ/kg}$$

and $\left. \begin{array}{l} P_2 = 1.2 \text{ MPa} \\ h_2 = 305.33 \text{ Btu/lbm} \end{array} \right\} s_2 = 1.0075 \text{ kJ/kg} \cdot \text{K}$

The heat added in the evaporator and that rejected in the condenser are

$$q_L = h_1 - h_4 = (233.09 - 108.26) \text{ kJ/kg} = 124.83 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = (305.33 - 108.26) \text{ kJ/kg} = 197.07 \text{ kJ/kg}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$x_{\text{destroyed},12} = T_0 (s_2 - s_1) = (303 \text{ K})(1.0075 - 0.9867) \text{ kJ/kg} \cdot \text{K} = 6.37 \text{ kJ/kg}$$

$$x_{\text{destroyed},23} = T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) = (303 \text{ K}) \left(0.39486 - 1.0075 + \frac{197.07 \text{ kJ/kg}}{303 \text{ K}} \right) = 11.44 \text{ kJ/kg}$$

$$x_{\text{destroyed},34} = T_0 (s_4 - s_3) = (303 \text{ K})(0.4585 - 0.39486) \text{ kJ/kg} \cdot \text{K} = \mathbf{19.28 \text{ kJ/kg}}$$

$$x_{\text{destroyed},41} = T_0 \left(s_1 - s_4 - \frac{q_L}{T_L} \right) = (303 \text{ K}) \left(0.9867 - 0.4585 - \frac{124.83 \text{ kJ/kg}}{(-34 + 273) \text{ K}} \right) = 1.80 \text{ kJ/kg}$$

The greatest exergy destruction occurs in the expansion valve. Note that heat is absorbed from fruits at -34°C (239 K) and rejected to the ambient air at 30°C (303 K), which is also taken as the dead state temperature. Alternatively, one may use the standard 25°C (298 K) as the dead state temperature, and perform the calculations accordingly.

11-120 A two-stage compression refrigeration system using refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the amount of heat removed from the refrigerated space, the compressor work, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flashing chamber is adiabatic.

Analysis (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables to be (Tables A-11, A-12, and A-13)

$$\begin{aligned} h_1 &= 242.86 \text{ kJ/kg}, & h_2 &= 267.72 \text{ kJ/kg} \\ h_3 &= 262.40 \text{ kJ/kg}, \\ h_5 &= 127.22 \text{ kJ/kg}, & h_6 &= 127.22 \text{ kJ/kg} \\ h_7 &= 81.51 \text{ kJ/kg}, & h_8 &= 81.51 \text{ kJ/kg} \end{aligned}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{127.22 - 81.51}{180.90} = 0.2527$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ (1)h_9 &= x_6 h_3 + (1 - x_6)h_2 \\ h_9 &= (0.2527)(262.40) + (1 - 0.2527)(267.72) = 266.38 \text{ kJ/kg} \\ P_9 &= 0.6 \text{ MPa} \\ h_9 &= 266.38 \text{ kJ/kg} \end{aligned} \left. \begin{array}{l} \\ \\ \end{array} \right\} s_9 = 0.93516 \text{ kJ/kg} \cdot \text{K}$$

Also,

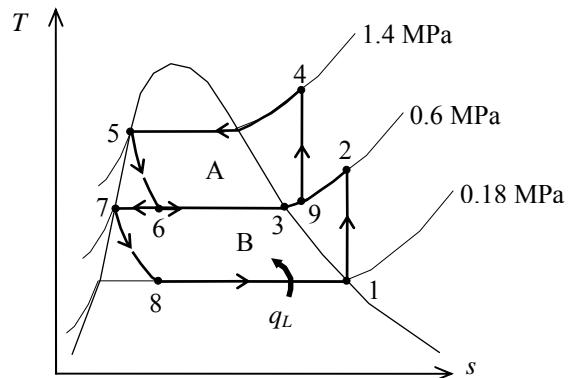

$$\left. \begin{array}{l} P_4 = 1.4 \text{ MPa} \\ s_4 = s_9 = 0.93516 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_4 = 284.23 \text{ kJ/kg}$$

Then the amount of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$\begin{aligned} q_L &= (1 - x_6)(h_1 - h_8) = (1 - 0.2527)(242.86 - 81.51) \text{ kJ/kg} = 120.6 \text{ kJ/kg} \\ w_{\text{in}} &= w_{\text{compl,in}} + w_{\text{complII,in}} = (1 - x_6)(h_2 - h_1) + (1)(h_4 - h_9) \\ &= (1 - 0.2527)(267.72 - 242.86) \text{ kJ/kg} + (284.23 - 266.38) \text{ kJ/kg} = 36.43 \text{ kJ/kg} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{120.6 \text{ kJ/kg}}{36.43 \text{ kJ/kg}} = 3.31$$

11-121E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The cooling load of both evaporators per unit of flow through the compressor and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 160 \text{ psia} = 48.519 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 48.519 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 30^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 30^\circ\text{F} = 107.40 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} T_7 = -29.5^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ -29.5^\circ\text{F} = 98.68 \text{ Btu/lbm}$$

For a unit mass flowing through the compressor, the fraction of mass flowing through Evaporator II is denoted by x and that through Evaporator I is y ($y = 1-x$). From the cooling loads specification,

$$\dot{Q}_{L,\text{evap}1} = 2\dot{Q}_{L,\text{evap}2}$$

$$x(h_5 - h_4) = 2y(h_7 - h_6)$$

where $x = 1 - y$

Combining these results and solving for y gives

$$y = \frac{h_5 - h_4}{2(h_7 - h_6) + (h_5 - h_4)} = \frac{107.40 - 48.519}{2(98.68 - 48.519) + (107.40 - 48.519)} = 0.3698$$

Then, $x = 1 - y = 1 - 0.3698 = 0.6302$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$xh_5 + yh_7 = h_1 \longrightarrow h_1 = \frac{xh_5 + yh_7}{1} = \frac{(0.6302)(107.40) + (0.3698)(98.68)}{1} = 104.18 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = P_{\text{sat} @ -29.5^\circ\text{F}} \cong 10 \text{ psia} \\ h_1 = 104.18 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2418 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 131.14 \text{ Btu/lbm}$$

The cooling load of both evaporators per unit mass through the compressor is

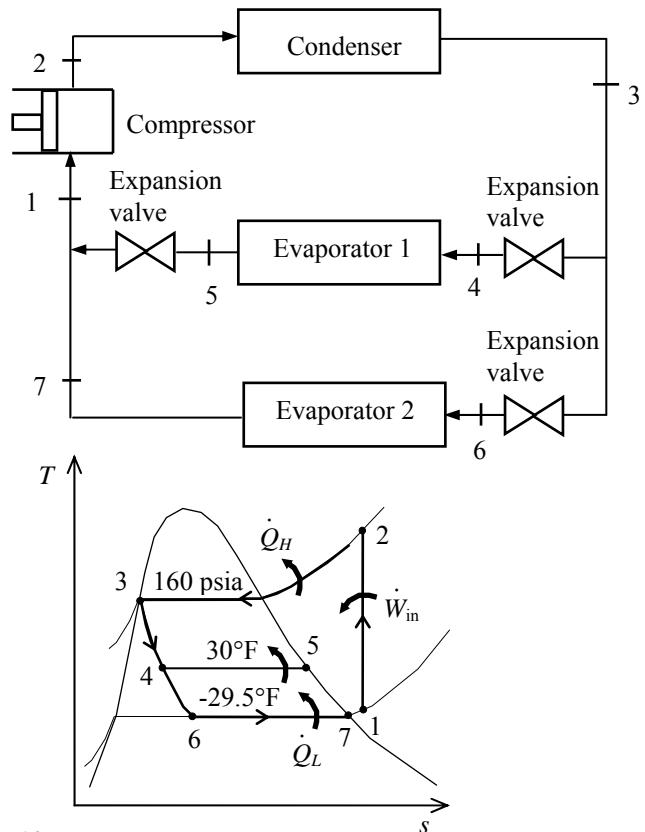

$$\begin{aligned} q_L &= x(h_5 - h_4) + y(h_7 - h_6) \\ &= (0.6302)(107.40 - 48.519) \text{ Btu/lbm} + (0.3698)(98.68 - 48.519) \text{ Btu/lbm} \\ &= \mathbf{55.7 \text{ Btu/lbm}} \end{aligned}$$

The work input to the compressor is

$$w_{\text{in}} = h_2 - h_1 = (131.14 - 104.18) \text{ Btu/lbm} = 27.0 \text{ Btu/lbm}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{55.7 \text{ Btu/lbm}}{27.0 \text{ Btu/lbm}} = \mathbf{2.06}$$

11-122E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Prob. 11-121E and the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\begin{aligned}s_1 &= s_2 = 0.2418 \text{ Btu/lbm} \cdot \text{R} \\s_3 &= 0.09774 \text{ Btu/lbm} \cdot \text{R} \\s_4 &= 0.1024 \text{ Btu/lbm} \cdot \text{R} \\s_5 &= 0.2226 \text{ Btu/lbm} \cdot \text{R} \\s_6 &= 0.1129 \text{ Btu/lbm} \cdot \text{R} \\s_7 &= 0.2295 \text{ Btu/lbm} \cdot \text{R} \\x &= 0.6302 \\y &= 1 - x = 0.3698 \\q_{L,45} &= h_5 - h_4 = 58.88 \text{ Btu/lbm} \\q_{L,67} &= h_7 - h_6 = 50.17 \text{ Btu/lbm} \\q_H &= 82.61 \text{ Btu/lbm}\end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives the exergy destructions per unit mass flowing through the compressor:

$$\begin{aligned}x_{\text{destroyed},23} &= T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) = (540 \text{ R}) \left(0.09774 - 0.2418 + \frac{82.61 \text{ Btu/lbm}}{540 \text{ R}} \right) = 4.82 \text{ Btu/lbm} \\x_{\text{destroyed},346} &= T_0 (xs_4 + ys_6 - s_3) \\&= (540 \text{ R})(0.6302 \times 0.1024 + 0.3698 \times 0.1129 - 0.09774) \text{ Btu/lbm} \cdot \text{R} = 4.60 \text{ Btu/lbm}\end{aligned}$$

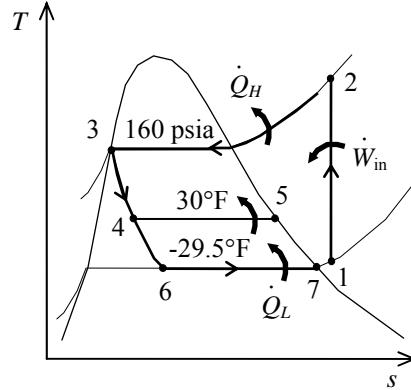

$$\begin{aligned}x_{\text{destroyed},45} &= xT_0 \left(s_5 - s_4 - \frac{q_{L,45}}{T_L} \right) \\&= (0.6302)(540 \text{ R}) \left(0.2226 - 0.1024 - \frac{58.88 \text{ Btu/lbm}}{500 \text{ R}} \right) = 0.84 \text{ Btu/lbm} \\x_{\text{destroyed},67} &= yT_0 \left(s_7 - s_6 - \frac{q_{L,67}}{T_L} \right) \\&= (0.3698)(540 \text{ R}) \left(0.2295 - 0.1129 - \frac{50.17 \text{ Btu/lbm}}{445 \text{ R}} \right) = 0.77 \text{ Btu/lbm}\end{aligned}$$

$$\begin{aligned}\dot{X}_{\text{destroyed,mixing}} &= T_0 (s_1 - xs_5 - ys_7) \\&= (540 \text{ R}) [0.2418 - (0.6302)(0.2226) - (0.3698)(0.2295)] = \mathbf{9.00 \text{ Btu/lbm}}\end{aligned}$$

For isentropic processes, the exergy destruction is zero:

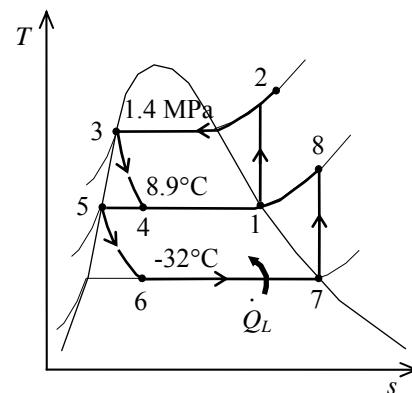

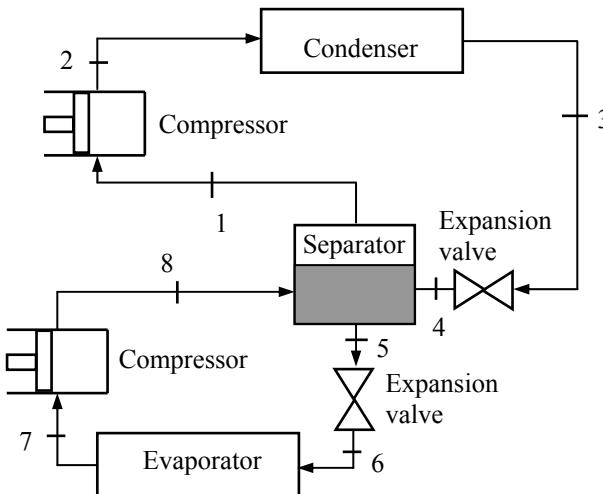

$$\dot{X}_{\text{destroyed},12} = 0$$

The greatest exergy destruction occurs during the mixing process. Note that heat is absorbed in evaporator 2 from a reservoir at -15°F (445 R), in evaporator 1 from a reservoir at 40°F (500 R), and rejected to a reservoir at 80°F (540 R), which is also taken as the dead state temperature.

11-123 A two-stage compression refrigeration system with a separation unit is considered. The rate of cooling and the power requirement are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 8.9^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 8.9^\circ\text{C} = 255.55 \text{ kJ/kg} \\ s_1 = s_g @ 8.9^\circ\text{C} = 0.92691 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = 1400 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 281.49 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1400 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1400 \text{ kPa} = 127.22 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 127.22 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 8.9^\circ\text{C} \\ \text{sat. liquid} \end{array} \right\} h_5 = h_f @ 8.9^\circ\text{C} = 63.94 \text{ kJ/kg}$$

$$h_6 \cong h_5 = 63.94 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_7 = -32^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_7 = h_g @ -32^\circ\text{C} = 230.91 \text{ kJ/kg} \\ s_7 = s_g @ -32^\circ\text{C} = 0.95813 \text{ kJ/kg}\cdot\text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_8 = P_{\text{sat}} @ 8.9^\circ\text{C} = 400 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_8 = 264.51 \text{ kJ/kg}$$

An energy balance on the separator gives

$$\dot{m}_6(h_8 - h_5) = \dot{m}_2(h_1 - h_4) \longrightarrow \dot{m}_6 = \dot{m}_2 \frac{h_1 - h_4}{h_8 - h_5} = (2 \text{ kg/s}) \frac{255.55 - 127.22}{264.51 - 63.94} = 1.280 \text{ kg/s}$$

The rate of cooling produced by this system is then

$$\dot{Q}_L = \dot{m}_6(h_7 - h_6) = (1.280 \text{ kg/s})(230.91 - 63.94) \text{ kJ/kg} = \mathbf{213.7 \text{ kJ/s}}$$

The total power input to the compressors is

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_6(h_8 - h_7) + \dot{m}_2(h_2 - h_1) \\ &= (1.280 \text{ kg/s})(264.51 - 230.91) \text{ kJ/kg} + (2 \text{ kg/s})(281.49 - 255.55) \text{ kJ/kg} = \mathbf{94.89 \text{ kW}} \end{aligned}$$

11-124 A two-stage vapor-compression refrigeration system with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Prob. 11-109 and the refrigerant tables (Tables A-11, A-12, and A-13),

$$s_1 = s_2 = 0.92691 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = 0.45315 \text{ kJ/kg} \cdot \text{K}$$

$$s_4 = 0.4720 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = 0.24761 \text{ kJ/kg} \cdot \text{K}$$

$$s_6 = 0.2658 \text{ kJ/kg} \cdot \text{K}$$

$$s_7 = s_8 = 0.95813 \text{ kJ/kg} \cdot \text{K}$$

$$\dot{m}_{\text{upper}} = 2 \text{ kg/s}$$

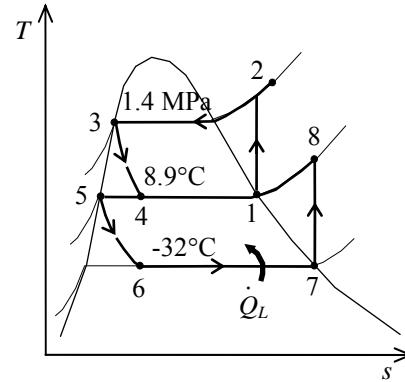

$$\dot{m}_{\text{lower}} = 1.280 \text{ kg/s}$$

$$q_L = h_7 - h_6 = 166.97 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = 154.27 \text{ kJ/kg}$$

$$T_L = -18 + 273 = 255 \text{ K}$$

$$T_H = T_0 = 25 + 273 = 298 \text{ K}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$\dot{x}_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} \dot{x}_{\text{destroyed}, 23} &= \dot{m}_{\text{upper}} T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) \\ &= (2 \text{ kg/s})(298 \text{ K}) \left(0.45315 - 0.92691 + \frac{154.27 \text{ kJ/kg}}{298 \text{ K}} \right) = \mathbf{26.18 \text{ kW}} \end{aligned}$$

$$\dot{x}_{\text{destroyed}, 34} = \dot{m}_{\text{upper}} T_0 (s_4 - s_3) = (2 \text{ kg/s})(298 \text{ K})(0.4720 - 0.45315) \text{ kJ/kg} \cdot \text{K} = 11.23 \text{ kW}$$

$$\dot{x}_{\text{destroyed}, 56} = \dot{m}_{\text{lower}} T_0 (s_6 - s_5) = (1.280 \text{ kg/s})(298 \text{ K})(0.2658 - 0.24761) \text{ kJ/kg} \cdot \text{K} = 6.94 \text{ kW}$$

$$\begin{aligned} \dot{x}_{\text{destroyed}, 67} &= \dot{m}_{\text{lower}} T_0 \left(s_7 - s_6 - \frac{q_L}{T_L} \right) \\ &= (1.280 \text{ kg/s})(298 \text{ K}) \left(0.95813 - 0.2658 - \frac{166.97 \text{ kJ/kg}}{255 \text{ K}} \right) = 14.32 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{x}_{\text{destroyed, separator}} &= T_0 [\dot{m}_{\text{lower}} (s_5 - s_8) + \dot{m}_{\text{upper}} (s_1 - s_4)] \\ &= (298 \text{ K})[(1.280 \text{ kg/s})(0.24761 - 0.95813) + (2 \text{ kg/s})(0.92691 - 0.4720)] = 0.11 \text{ kW} \end{aligned}$$

For isentropic processes, the exergy destruction is zero:

$$\dot{x}_{\text{destroyed}, 12} = 0$$

$$\dot{x}_{\text{destroyed}, 78} = 0$$

Note that heat is absorbed from a reservoir at 0°F (460 R) and rejected to the standard ambient air at 77°F (537 R), which is also taken as the dead state temperature. The greatest exergy destruction occurs during the condensation process.

11-125 A regenerative gas refrigeration cycle with helium as the working fluid is considered. The temperature of the helium at the turbine inlet, the COP of the cycle, and the net power input required are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Helium is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

Properties The properties of helium are $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis (a) The temperature of the helium at the turbine inlet is determined from an energy balance on the regenerator,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta\dot{E}_{\text{system}}^{\text{0(steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \longrightarrow \dot{m}(h_3 - h_4) = \dot{m}(h_1 - h_6) \end{aligned}$$

or,

$$\dot{m}c_p(T_3 - T_4) = \dot{m}c_p(T_1 - T_6) \longrightarrow T_3 - T_4 = T_1 - T_6$$

Thus,

$$T_4 = T_3 - T_1 + T_6 = 20^\circ\text{C} - (-10^\circ\text{C}) + (-25^\circ\text{C}) = 5^\circ\text{C} = 278 \text{ K}$$

(b) From the isentropic relations,

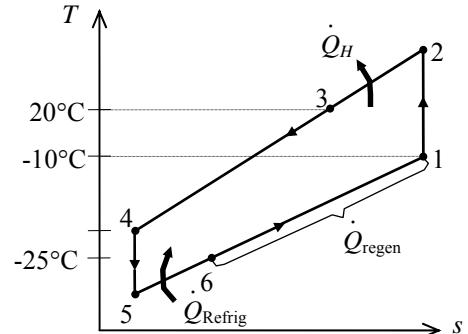

$$\begin{aligned} T_2 &= T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (263 \text{ K}) (3)^{0.667/1.667} = 408.2 \text{ K} = 135.2^\circ\text{C} \\ T_5 &= T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (278 \text{ K}) \left(\frac{1}{3} \right)^{0.667/1.667} = 179.1 \text{ K} = -93.9^\circ\text{C} \end{aligned}$$

Then the COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} = \frac{h_6 - h_5}{(h_2 - h_1) - (h_4 - h_5)} \\ &= \frac{T_6 - T_5}{(T_2 - T_1) - (T_4 - T_5)} = \frac{-25^\circ\text{C} - (-93.9^\circ\text{C})}{[135.2 - (-10)]^\circ\text{C} - [5 - (-93.9)]^\circ\text{C}} = 1.49 \end{aligned}$$

(c) The net power input is determined from

$$\begin{aligned} \dot{W}_{\text{net,in}} &= \dot{W}_{\text{comp,in}} - \dot{W}_{\text{turb,out}} = \dot{m}[(h_2 - h_1) - (h_4 - h_5)] \\ &= \dot{m}c_p[(T_2 - T_1) - (T_4 - T_5)] \\ &= (0.45 \text{ kg/s})(5.1926 \text{ kJ/kg}\cdot\text{°C})[[135.2 - (-10)] - [5 - (-93.9)]] \\ &= 108.2 \text{ kW} \end{aligned}$$

11-126 An absorption refrigeration system operating at specified conditions is considered. The minimum rate of heat supply required is to be determined.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{368 \text{ K}}\right) \left(\frac{275}{298 - 275}\right) = 2.274$$

Thus,

$$\dot{Q}_{\text{gen,min}} = \frac{\dot{Q}_L}{\text{COP}_{R,\max}} = \frac{28 \text{ kW}}{2.274} = 12.3 \text{ kW}$$

11-127 Problem 11-126 is reconsidered. The effect of the source temperature on the minimum rate of heat supply is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data:"

$$\begin{aligned} T_L &= 2 \text{ [C]} \\ T_0 &= 25 \text{ [C]} \\ T_s &= 95 \text{ [C]} \\ Q_{\text{dot_L}} &= 28 \text{ [kW]} \end{aligned}$$

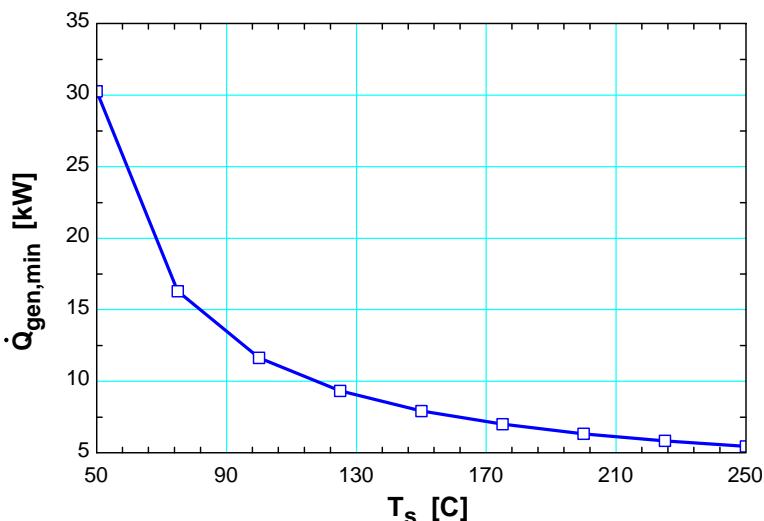

"The maximum COP that this refrigeration system can have is:"

$$\text{COP}_{R,\max} = (1 - (T_0 + 273) / (T_s + 273)) * ((T_L + 273) / (T_0 - T_L))$$

"The minimum rate of heat supply is:"

$$Q_{\text{dot_gen_min}} = Q_{\text{dot_L}} / \text{COP}_{R,\max}$$

T_s [C]	$Q_{\text{gen,min}}$ [kW]
50	30.26
75	16.3
100	11.65
125	9.32
150	7.925
175	6.994
200	6.33
225	5.831
250	5.443

11-128 A regenerative gas refrigeration cycle using air as the working fluid is considered. The effectiveness of the regenerator, the rate of heat removal from the refrigerated space, the COP of the cycle, and the refrigeration load and the COP if this system operated on the simple gas refrigeration cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) For this problem, we use the properties of air from EES. Note that for an ideal gas enthalpy is a function of temperature only while entropy is functions of both temperature and pressure.

$$T_1 = 0^\circ\text{C} \longrightarrow h_1 = 273.40 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_1 = 100 \text{ kPa} \\ T_1 = 0^\circ\text{C} \end{array} \right\} s_1 = 5.6110 \text{ kJ/kg.K}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 433.50 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{433.50 - 273.40}{h_2 - 273.40}$$

$$h_2 = 473.52 \text{ kJ/kg}$$

$$T_3 = 35^\circ\text{C} \longrightarrow h_3 = 308.63 \text{ kJ/kg}$$

For the turbine inlet and exit we have

$$T_5 = -80^\circ\text{C} \longrightarrow h_5 = 193.45 \text{ kJ/kg}$$

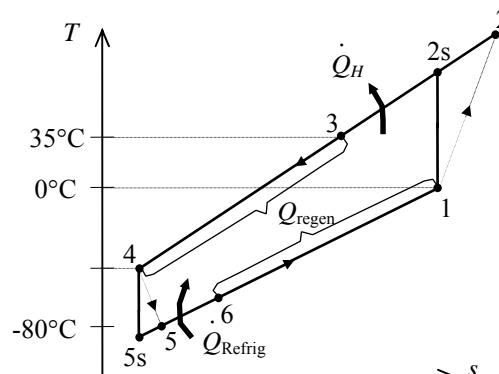

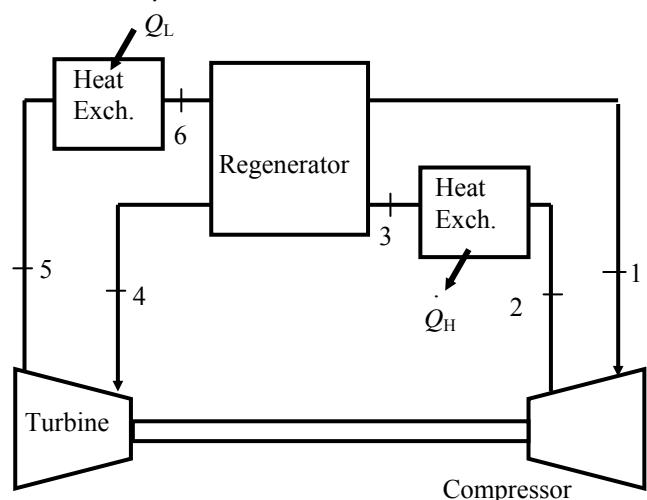

$$T_4 = ? \longrightarrow h_4 =$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}}$$

$$\left. \begin{array}{l} P_1 = 100 \text{ kPa} \\ T_1 = 0^\circ\text{C} \end{array} \right\} s_1 = 5.6110 \text{ kJ/kg.K}$$

$$\left. \begin{array}{l} P_4 = 500 \text{ kPa} \\ T_4 = ? \end{array} \right\} s_4 =$$

$$\left. \begin{array}{l} P_5 = 500 \text{ kPa} \\ s_5 = s_4 \end{array} \right\} h_{5s} =$$

We can determine the temperature at the turbine inlet from EES using the above relations. A hand solution would require a trial-error approach.

$$T_4 = 281.8 \text{ K}, \quad h_4 = 282.08 \text{ kJ/kg}$$

An energy balance on the regenerator gives

$$h_6 = h_1 - h_3 + h_4 = 273.40 - 308.63 + 282.08 = 246.85 \text{ kJ/kg}$$

The effectiveness of the regenerator is determined from

$$\varepsilon_{\text{regen}} = \frac{h_3 - h_4}{h_3 - h_6} = \frac{308.63 - 282.08}{308.63 - 246.85} = \mathbf{0.430}$$

(b) The refrigeration load is

$$\dot{Q}_L = \dot{m}(h_6 - h_5) = (0.4 \text{ kg/s})(246.85 - 193.45) \text{ kJ/kg} = \mathbf{21.36 \text{ kW}}$$

(c) The turbine and compressor powers and the COP of the cycle are

$$\dot{W}_{C,in} = \dot{m}(h_2 - h_1) = (0.4 \text{ kg/s})(473.52 - 273.40) \text{ kJ/kg} = 80.05 \text{ kW}$$

$$\dot{W}_{T,out} = \dot{m}(h_4 - h_5) = (0.4 \text{ kg/s})(282.08 - 193.45) \text{ kJ/kg} = 35.45 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{net,in}} = \frac{\dot{Q}_L}{\dot{W}_{C,in} - \dot{W}_{T,out}} = \frac{21.36}{80.05 - 35.45} = \mathbf{0.479}$$

(d) The simple gas refrigeration cycle analysis is as follows:

$$h_1 = 273.40 \text{ kJ/kg}$$

$$h_2 = 473.52 \text{ kJ/kg}$$

$$h_3 = 308.63 \text{ kJ/kg}$$

$$\begin{aligned} P_3 &= 500 \text{ kPa} \\ T_3 &= 35^\circ\text{C} \end{aligned} \quad \left. \begin{aligned} s_3 &= 5.2704 \text{ kJ/kg.K} \end{aligned} \right\}$$

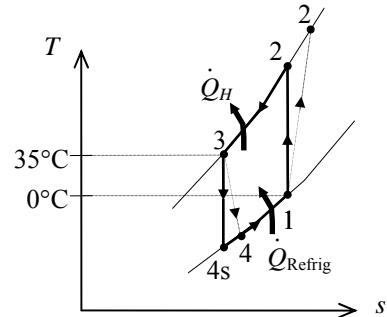

$$\begin{aligned} P_1 &= 100 \text{ kPa} \\ s_4 &= s_3 \end{aligned} \quad \left. \begin{aligned} h_{4s} &= 194.52 \text{ kJ/kg.K} \end{aligned} \right\}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.85 = \frac{308.63 - h_4}{308.63 - 194.52} \longrightarrow h_4 = 211.64 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.4 \text{ kg/s})(273.40 - 211.64) \text{ kJ/kg} = \mathbf{24.70 \text{ kW}}$$

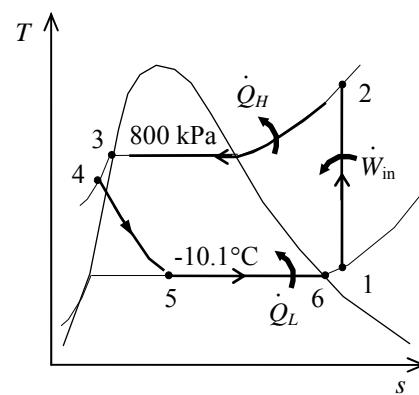

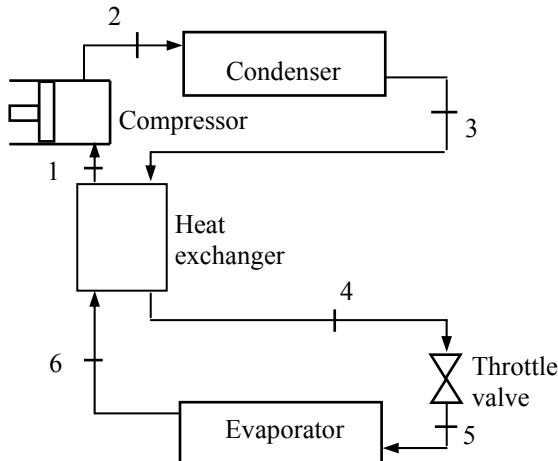

$$\dot{W}_{net,in} = \dot{m}(h_2 - h_1) - \dot{m}(h_3 - h_4) = (0.4 \text{ kg/s})[(473.52 - 273.40) - (308.63 - 211.64) \text{ kJ/kg}] = 41.25 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{net,in}} = \frac{24.70}{41.25} = \mathbf{0.599}$$

11-129 An innovative vapor-compression refrigeration system with a heat exchanger is considered. The system's COP is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = T_{\text{sat}} @ 800 \text{ kPa} - 11.3 \\ = 31.3 - 11.3 = 20^\circ\text{C} \\ P_4 = 800 \text{ kPa} \end{array} \right\} h_4 \cong h_f @ 20^\circ\text{C} = 79.32 \text{ kJ/kg}$$

$$h_5 \cong h_4 = 79.32 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_6 = -10.1^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_6 = h_g @ -10.1^\circ\text{C} = 244.46 \text{ kJ/kg}$$

$$P_6 = P_{\text{sat}} @ -10.1^\circ\text{C} = 200 \text{ kPa}$$

An energy balance on the heat exchanger gives

$$\dot{m}(h_1 - h_6) = \dot{m}(h_3 - h_4) \longrightarrow h_1 = h_3 - h_4 + h_6 = 95.47 - 79.32 + 244.46 = 260.61 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ h_1 = 260.61 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9970 \text{ kJ/kg}\cdot\text{K}$$

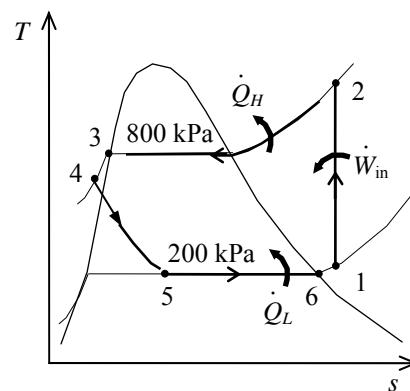

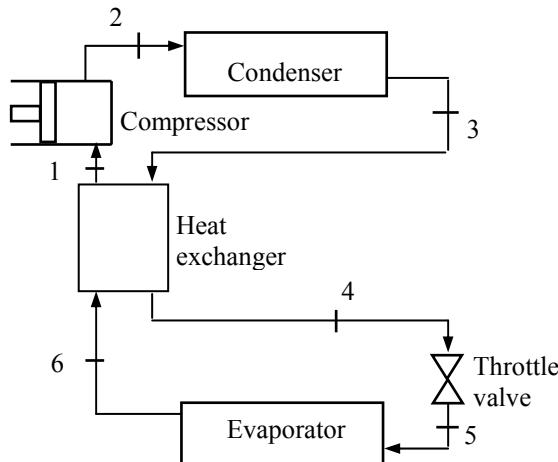

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 292.17 \text{ kJ/kg}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_6 - h_5}{h_2 - h_1} = \frac{244.46 - 79.32}{292.17 - 260.61} = 5.23$$

11-130 An innovative vapor-compression refrigeration system with a heat exchanger is considered. The system's COP is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = T_{\text{sat}} @ 800 \text{ kPa} - 21.3 \\ = 31.3 - 21.3 = 10^\circ\text{C} \\ P_4 = 800 \text{ kPa} \end{array} \right\} h_4 \cong h_f @ 10^\circ\text{C} = 65.43 \text{ kJ/kg}$$

$$h_5 \cong h_4 = 65.43 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_6 = -10.1^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_6 = h_g @ -10.1^\circ\text{C} = 244.46 \text{ kJ/kg}$$

$$P_6 = P_{\text{sat}} @ -10.1^\circ\text{C} = 200 \text{ kPa}$$

An energy balance on the heat exchanger gives

$$\dot{m}(h_1 - h_6) = \dot{m}(h_3 - h_4) \longrightarrow h_1 = h_3 - h_4 + h_6 = 95.47 - 65.43 + 244.46 = 274.50 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ h_1 = 274.50 \text{ kJ/kg} \end{array} \right\} s_1 = 1.0449 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 308.28 \text{ kJ/kg}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_6 - h_5}{h_2 - h_1} = \frac{244.46 - 65.43}{308.28 - 274.50} = \mathbf{5.30}$$

11-131 An ideal gas refrigeration cycle with three stages of compression with intercooling using air as the working fluid is considered. The COP of this system is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

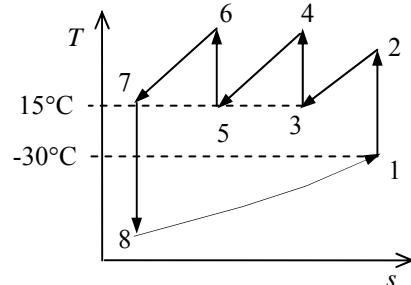

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis From the isentropic relations,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (243 \text{ K}) (7)^{0.4/1.4} = 423.7 \text{ K}$$

$$T_4 = T_6 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (288 \text{ K}) (7)^{0.4/1.4} = 502.2 \text{ K}$$

$$T_8 = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (288 \text{ K}) \left(\frac{1}{7 \times 7 \times 7} \right)^{0.4/1.4} = 54.3 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_8}{(h_2 - h_1) + (h_4 - h_3) + (h_6 - h_5) - (h_7 - h_8)} \\ &= \frac{T_1 - T_8}{(T_2 - T_1) + 2(T_4 - T_3) - (T_7 - T_8)} \\ &= \frac{243 - 54.3}{(423.7 - 243) + 2(502.2 - 288) - (288 - 54.3)} \\ &= \mathbf{0.503} \end{aligned}$$

11-132 A vortex tube receives compressed air at 500 kPa and 300 K, and supplies 25 percent of it as cold air and the rest as hot air. The COP of the vortex tube is to be compared to that of a reversed Brayton cycle for the same pressure ratio; the exit temperature of the hot fluid stream and the COP are to be determined; and it is to be shown if this process violates the second law.

Assumptions 1 The vortex tube is adiabatic. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Steady operating conditions exist.

Properties The gas constant of air is 0.287 kJ/kg.K (Table A-1). The specific heat of air at room temperature is $c_p = 1.005$ kJ/kg.K (Table A-2). The enthalpy of air at absolute temperature T can be expressed in terms of specific heats as $h = c_p T$.

Analysis (a) The COP of the vortex tube is much lower than the COP of a reversed Brayton cycle of the same pressure ratio since the vortex tube involves *vortices*, which are highly irreversible. Owing to this irreversibility, the minimum temperature that can be obtained by the vortex tube is not as low as the one that can be obtained by the revered Brayton cycle.

(b) We take the vortex tube as the system. This is a steady flow system with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow energy balance equation for this system $\dot{E}_{in} = \dot{E}_{out}$ for a unit mass flow rate at the inlet ($\dot{m}_1 = 1 \text{ kg/s}$) can be expressed as

$$\begin{aligned}\dot{m}_1 h_1 &= \dot{m}_2 h_2 + \dot{m}_3 h_3 \\ \dot{m}_1 c_p T_1 &= \dot{m}_2 c_p T_2 + \dot{m}_3 c_p T_3 \\ 1c_p T_1 &= 0.25c_p T_2 + 0.75c_p T_3\end{aligned}$$

Cancelling c_p and solving for T_3 gives

$$T_3 = \frac{T_1 - 0.25T_2}{0.75} = \frac{300 - 0.25 \times 278}{0.75} = 307.3 \text{ K}$$

Therefore, the hot air stream will leave the vortex tube at an average temperature of 307.3 K.

(c) The entropy balance for this steady flow system $\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = 0$ can be expressed as with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow entropy balance equation for this system for a unit mass flow rate at the inlet ($\dot{m}_1 = 1 \text{ kg/s}$) can be expressed

$$\begin{aligned}\dot{S}_{gen} &= \dot{S}_{out} - \dot{S}_{in} \\ &= \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_1 s_1 = \dot{m}_2 s_2 + \dot{m}_3 s_3 - (\dot{m}_2 + \dot{m}_3)s_1 \\ &= \dot{m}_2(s_2 - s_1) + \dot{m}_3(s_3 - s_1) \\ &= 0.25(s_2 - s_1) + 0.75(s_3 - s_1) \\ &= 0.25 \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) + 0.75 \left(c_p \ln \frac{T_3}{T_1} - R \ln \frac{P_3}{P_1} \right)\end{aligned}$$

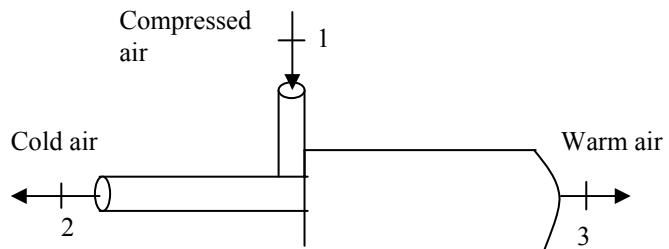

Substituting the known quantities, the rate of entropy generation is determined to be

$$\begin{aligned}\dot{S}_{gen} &= 0.25 \left((1.005 \text{ kJ/kg.K}) \ln \frac{278 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{500 \text{ kPa}} \right) \\ &\quad + 0.75 \left((1.005 \text{ kJ/kg.K}) \ln \frac{307.3 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{500 \text{ kPa}} \right) \\ &= 0.461 \text{ kW/K} > 0\end{aligned}$$

which is a positive quantity. Therefore, this process **satisfies** the 2nd law of thermodynamics.

(d) For a unit mass flow rate at the inlet ($\dot{m}_1 = 1 \text{ kg/s}$), the cooling rate and the power input to the compressor are determined to

$$\begin{aligned}\dot{Q}_{cooling} &= \dot{m}_c (h_1 - h_c) = \dot{m}_c c_p (T_1 - T_c) \\ &= (0.25 \text{ kg/s})(1.005 \text{ kJ/kg.K})(300 - 278) \text{ K} = 5.53 \text{ kW}\end{aligned}$$

$$\begin{aligned}\dot{W}_{\text{comp,in}} &= \frac{\dot{m}_0 R T_0}{(k-1)\eta_{\text{comp}}} \left[\left(\frac{P_1}{P_0} \right)^{(k-1)/k} - 1 \right] \\ &= \frac{(1 \text{ kg/s})(0.287 \text{ kJ/kg.K})(300 \text{ K})}{(1.4-1)0.80} \left[\left(\frac{500 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.4-1)/1.4} - 1 \right] = 157.1 \text{ kW}\end{aligned}$$

Then the COP of the vortex refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{comp,in}}} = \frac{5.53 \text{ kW}}{157.1 \text{ kW}} = \mathbf{0.035}$$

The COP of a Carnot refrigerator operating between the same temperature limits of 300 K and 278 K is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{278 \text{ K}}{(300 - 278) \text{ K}} = \mathbf{12.6}$$

Discussion Note that the COP of the vortex refrigerator is a small fraction of the COP of a Carnot refrigerator operating between the same temperature limits.

11-133 A vortex tube receives compressed air at 600 kPa and 300 K, and supplies 25 percent of it as cold air and the rest as hot air. The COP of the vortex tube is to be compared to that of a reversed Brayton cycle for the same pressure ratio; the exit temperature of the hot fluid stream and the COP are to be determined; and it is to be shown if this process violates the second law.

Assumptions 1 The vortex tube is adiabatic. 2 Air is an ideal gas with constant specific heats at room temperature. 3 Steady operating conditions exist.

Properties The gas constant of air is 0.287 kJ/kg.K (Table A-1). The specific heat of air at room temperature is $c_p = 1.005$ kJ/kg.K (Table A-2). The enthalpy of air at absolute temperature T can be expressed in terms of specific heats as $h = c_p T$.

Analysis (a) The COP of the vortex tube is much lower than the COP of a reversed Brayton cycle of the same pressure ratio since the vortex tube involves *vortices*, which are highly irreversible. Owing to this irreversibility, the minimum temperature that can be obtained by the vortex tube is not as low as the one that can be obtained by the revered Brayton cycle.

(b) We take the vortex tube as the system. This is a steady flow system with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow entropy balance equation for this system $\dot{E}_{in} = \dot{E}_{out}$ for a unit mass flow rate at the inlet ($\dot{m}_1 = 1 \text{ kg/s}$) can be expressed as

$$\begin{aligned}\dot{m}_1 h_1 &= \dot{m}_2 h_2 + \dot{m}_3 h_3 \\ \dot{m}_1 c_p T_1 &= \dot{m}_2 c_p T_2 + \dot{m}_3 c_p T_3 \\ 1 c_p T_1 &= 0.25 c_p T_2 + 0.75 c_p T_3\end{aligned}$$

Cancelling c_p and solving for T_3 gives

$$T_3 = \frac{T_1 - 0.25 T_2}{0.75} = \frac{300 - 0.25 \times 278}{0.75} = 307.3 \text{ K}$$

Therefore, the hot air stream will leave the vortex tube at an average temperature of 307.3 K.

(c) The entropy balance for this steady flow system $\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = 0$ can be expressed as with one inlet and two exits, and it involves no heat or work interactions. Then the steady-flow energy balance equation for this system for a unit mass flow rate at the inlet ($\dot{m}_1 = 1 \text{ kg/s}$) can be expressed

$$\begin{aligned}\dot{S}_{gen} &= \dot{S}_{out} - \dot{S}_{in} \\ &= \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_1 s_1 = \dot{m}_2 s_2 + \dot{m}_3 s_3 - (\dot{m}_2 + \dot{m}_3) s_1 \\ &= \dot{m}_2 (s_2 - s_1) + \dot{m}_3 (s_3 - s_1) \\ &= 0.25(s_2 - s_1) + 0.75(s_3 - s_1) \\ &= 0.25 \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) + 0.75 \left(c_p \ln \frac{T_3}{T_1} - R \ln \frac{P_3}{P_1} \right)\end{aligned}$$

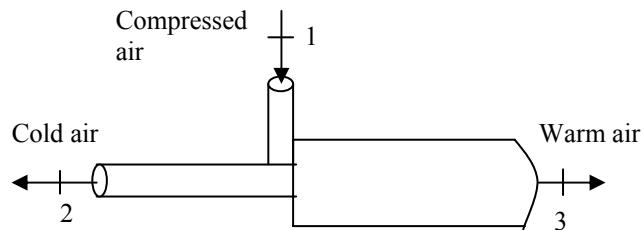

Substituting the known quantities, the rate of entropy generation is determined to be

$$\begin{aligned}\dot{S}_{gen} &= 0.25 \left((1.005 \text{ kJ/kg.K}) \ln \frac{278 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{600 \text{ kPa}} \right) \\ &\quad + 0.75 \left((1.005 \text{ kJ/kg.K}) \ln \frac{307.3 \text{ K}}{300 \text{ K}} - (0.287 \text{ kJ/kg.K}) \ln \frac{100 \text{ kPa}}{600 \text{ kPa}} \right) \\ &= 0.513 \text{ kW/K} > 0\end{aligned}$$

which is a positive quantity. Therefore, this process **satisfies** the 2nd law of thermodynamics.

(d) For a unit mass flow rate at the inlet ($\dot{m}_1 = 1 \text{ kg/s}$), the cooling rate and the power input to the compressor are determined to

$$\begin{aligned}\dot{Q}_{cooling} &= \dot{m}_c (h_1 - h_c) = \dot{m}_c c_p (T_1 - T_c) \\ &= (0.25 \text{ kg/s})(1.005 \text{ kJ/kg.K})(300 - 278) \text{ K} = 5.53 \text{ kW}\end{aligned}$$

$$\begin{aligned}\dot{W}_{\text{comp,in}} &= \frac{\dot{m}_0 R T_0}{(k-1)\eta_{\text{comp}}} \left[\left(\frac{P_1}{P_0} \right)^{(k-1)/k} - 1 \right] \\ &= \frac{(1 \text{ kg/s})(0.287 \text{ kJ/kg.K})(300 \text{ K})}{(1.4-1)0.80} \left[\left(\frac{600 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.4-1)/1.4} - 1 \right] = 179.9 \text{ kW}\end{aligned}$$

Then the COP of the vortex refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{comp,in}}} = \frac{5.53 \text{ kW}}{179.9 \text{ kW}} = \mathbf{0.031}$$

The COP of a Carnot refrigerator operating between the same temperature limits of 300 K and 278 K is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{278 \text{ K}}{(300 - 278) \text{ K}} = \mathbf{12.6}$$

Discussion Note that the COP of the vortex refrigerator is a small fraction of the COP of a Carnot refrigerator operating between the same temperature limits.

11-134 The effect of the evaporator pressure on the COP of an ideal vapor-compression refrigeration cycle with R-134a as the working fluid is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

11-136 A relation for the COP of the two-stage refrigeration system with a flash chamber shown in Fig. 11-12 is to be derived.

Analysis The coefficient of performance is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}}$$

where

$$q_L = (1 - x_6)(h_1 - h_8) \quad \text{with} \quad x_6 = \frac{h_6 - h_f}{h_{fg}}$$

$$w_{\text{in}} = w_{\text{compI,in}} + w_{\text{compII,in}} = (1 - x_6)(h_2 - h_1) + (1)(h_4 - h_9)$$

Fundamentals of Engineering (FE) Exam Problems

11-137 Consider a heat pump that operates on the reversed Carnot cycle with R-134a as the working fluid executed under the saturation dome between the pressure limits of 140 kPa and 800 kPa. R-134a changes from saturated vapor to saturated liquid during the heat rejection process. The net work input for this cycle is

- (a) 28 kJ/kg (b) 34 kJ/kg (c) 49 kJ/kg (d) 144 kJ/kg (e) 275 kJ/kg

Answer (a) 28 kJ/kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=800 "kPa"
P2=140 "kPa"
h_fg=ENTHALPY(R134a,x=1,P=P1)-ENTHALPY(R134a,x=0,P=P1)
TH=TEMPERATURE(R134a,x=0,P=P1)+273
TL=TEMPERATURE(R134a,x=0,P=P2)+273
q_H=h_fg
COP=TH/(TH-TL)
w_net=q_H/COP
```

"Some Wrong Solutions with Common Mistakes:"

W1_work = q_H/COP1; COP1=TL/(TH-TL) **"Using COP of regrigerator"**

Partial Derivatives and Associated Relations

12-1C For functions that depend on one variable, they are identical. For functions that depend on two or more variables, the partial differential represents the change in the function with one of the variables as the other variables are held constant. The ordinary differential for such functions represents the total change as a result of differential changes in all variables.

12-2C (a) $(\partial x)_y = dx$; (b) $(\partial z)_y \leq dz$; and (c) $dz = (\partial z)_x + (\partial z)_y$

12-3C Yes.

12-4C Yes.

12-5 Air at a specified temperature and specific volume is considered. The changes in pressure corresponding to a certain increase of different properties are to be determined.

Assumptions Air is an ideal gas.

Properties The gas constant of air is $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ (Table A-1).

Analysis An ideal gas equation can be expressed as $P = RT/v$. Noting that R is a constant and $P = P(T, v)$,

$$dP = \left(\frac{\partial P}{\partial T} \right)_v dT + \left(\frac{\partial P}{\partial v} \right)_T dv = \frac{RdT}{v} - \frac{RTdv}{v^2}$$

(a) The change in T can be expressed as $dT \equiv \Delta T = 300 \times 0.01 = 3.0 \text{ K}$. At $v = \text{constant}$,

$$(dP)_v = \frac{RdT}{v} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(3.0 \text{ K})}{1.2 \text{ m}^3/\text{kg}} = \mathbf{0.7175 \text{ kPa}}$$

(b) The change in v can be expressed as $dv \equiv \Delta v = 1.2 \times 0.01 = 0.012 \text{ m}^3/\text{kg}$. At $T = \text{constant}$,

$$(dP)_T = -\frac{RTdv}{v^2} = -\frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})(0.012 \text{ m}^3/\text{kg})}{(1.2 \text{ m}^3/\text{kg})^2} = \mathbf{-0.7175 \text{ kPa}}$$

(c) When both v and T increases by 1%, the change in P becomes

$$dP = (dP)_v + (dP)_T = 0.7175 + (-0.7175) = \mathbf{0}$$

Thus the changes in T and v balance each other.

12-6 Helium at a specified temperature and specific volume is considered. The changes in pressure corresponding to a certain increase of different properties are to be determined.

Assumptions Helium is an ideal gas

Properties The gas constant of helium is $R = 2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ (Table A-1).

Analysis An ideal gas equation can be expressed as $P = RT/v$. Noting that R is a constant and $P = P(T, v)$,

$$dP = \left(\frac{\partial P}{\partial T} \right)_v dT + \left(\frac{\partial P}{\partial v} \right)_T dv = \frac{RdT}{v} - \frac{RTdv}{v^2}$$

(a) The change in T can be expressed as $dT \approx \Delta T = 300 \times 0.01 = 3.0 \text{ K}$. At $v = \text{constant}$,

$$(dP)_v = \frac{RdT}{v} = \frac{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(3.0 \text{ K})}{1.2 \text{ m}^3/\text{kg}} = \mathbf{5.192 \text{ kPa}}$$

(b) The change in v can be expressed as $dv \approx \Delta v = 1.2 \times 0.01 = 0.012 \text{ m}^3/\text{kg}$. At $T = \text{constant}$,

$$(dP)_T = -\frac{RTdv}{v^2} = \frac{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})(0.012 \text{ m}^3)}{(1.2 \text{ m}^3/\text{kg})^2} = \mathbf{-5.192 \text{ kPa}}$$

(c) When both v and T increases by 1%, the change in P becomes

$$dP = (dP)_v + (dP)_T = 5.192 + (-5.192) = \mathbf{0}$$

Thus the changes in T and v balance each other.

12-7 Nitrogen gas at a specified state is considered. The c_p and c_v of the nitrogen are to be determined using Table A-18, and to be compared to the values listed in Table A-2b.

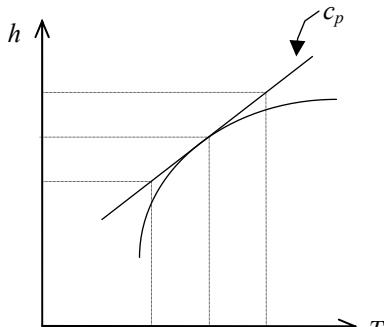

Analysis The c_p and c_v of ideal gases depends on temperature only, and are expressed as $c_p(T) = dh(T)/dT$ and $c_v(T) = du(T)/dT$. Approximating the differentials as differences about 400 K, the c_p and c_v values are determined to be

$$\begin{aligned} c_p(400 \text{ K}) &= \left(\frac{dh(T)}{dT} \right)_{T=400 \text{ K}} \cong \left(\frac{\Delta h(T)}{\Delta T} \right)_{T \approx 400 \text{ K}} \\ &= \frac{h(410 \text{ K}) - h(390 \text{ K})}{(410 - 390) \text{ K}} \\ &= \frac{(11,932 - 11,347)/28.0 \text{ kJ/kg}}{(410 - 390) \text{ K}} \\ &= \mathbf{1.045 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

(Compare: Table A-2b at 400 K $\rightarrow c_p = 1.044 \text{ kJ/kg}\cdot\text{K}$)

$$\begin{aligned} c_v(400 \text{ K}) &= \left(\frac{du(T)}{dT} \right)_{T=400 \text{ K}} \cong \left(\frac{\Delta u(T)}{\Delta T} \right)_{T \approx 400 \text{ K}} \\ &= \frac{u(410 \text{ K}) - u(390 \text{ K})}{(410 - 390) \text{ K}} \\ &= \frac{(8,523 - 8,104)/28.0 \text{ kJ/kg}}{(410 - 390) \text{ K}} = \mathbf{0.748 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

(Compare: Table A-2b at 400 K $\rightarrow c_v = 0.747 \text{ kJ/kg}\cdot\text{K}$)

12-8E Nitrogen gas at a specified state is considered. The c_p and c_v of the nitrogen are to be determined using Table A-18E, and to be compared to the values listed in Table A-2Eb.

Analysis The c_p and c_v of ideal gases depends on temperature only, and are expressed as $c_p(T) = dh(T)/dT$ and $c_v(T) = du(T)/dT$. Approximating the differentials as differences about 600 R, the c_p and c_v values are determined to be

$$\begin{aligned} c_p(800 \text{ R}) &= \left(\frac{dh(T)}{dT} \right)_{T=800 \text{ R}} \cong \left(\frac{\Delta h(T)}{\Delta T} \right)_{T \approx 800 \text{ R}} \\ &= \frac{h(820 \text{ R}) - h(780 \text{ R})}{(820 - 780)\text{R}} \\ &= \frac{(5704.7 - 5424.2)/28.013 \text{ Btu/lbm}}{(820 - 780)\text{R}} = \mathbf{0.250 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(Compare: Table A-2Eb at 800 R = 340°F → $c_p = 0.250 \text{ Btu/lbm} \cdot \text{R}$)

$$\begin{aligned} c_v(800 \text{ R}) &= \left(\frac{du(T)}{dT} \right)_{T=800 \text{ R}} \cong \left(\frac{\Delta u(T)}{\Delta T} \right)_{T \approx 800 \text{ R}} \\ &= \frac{u(820 \text{ R}) - u(780 \text{ R})}{(820 - 780)\text{R}} \\ &= \frac{(4076.3 - 3875.2)/28.013 \text{ Btu/lbm}}{(820 - 780)\text{R}} = \mathbf{0.179 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(Compare: Table A-2Eb at 800 R = 340°F → $c_v = 0.179 \text{ Btu/lbm} \cdot \text{R}$)

12-9 The state of an ideal gas is altered slightly. The change in the specific volume of the gas is to be determined using differential relations and the ideal-gas relation at each state.

Assumptions The gas is air and air is an ideal gas.

Properties The gas constant of air is $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ (Table A-1).

Analysis (a) The changes in T and P can be expressed as

$$dT \equiv \Delta T = (404 - 400)\text{K} = 4 \text{ K}$$

$$dP \equiv \Delta P = (96 - 100)\text{kPa} = -4 \text{ kPa}$$

The ideal gas relation $Pv = RT$ can be expressed as $v = v(T, P)$. Note that R is a constant and $v = v(T, P)$. Applying the total differential relation and using average values for T and P,

$$\begin{aligned} dv &= \left(\frac{\partial v}{\partial T}\right)_P dT + \left(\frac{\partial v}{\partial P}\right)_T dP = \frac{RdT}{P} - \frac{RTdP}{P^2} \\ &= (0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}) \left(\frac{4 \text{ K}}{98 \text{ kPa}} - \frac{(402 \text{ K})(-4 \text{ kPa})}{(98 \text{ kPa})^2} \right) \\ &= (0.0117 \text{ m}^3/\text{kg}) + (0.04805 \text{ m}^3/\text{kg}) = \mathbf{0.0598 \text{ m}^3/\text{kg}} \end{aligned}$$

(b) Using the ideal gas relation at each state,

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(400 \text{ K})}{100 \text{ kPa}} = 1.1480 \text{ m}^3/\text{kg}$$

$$v_2 = \frac{RT_2}{P_2} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(404 \text{ K})}{96 \text{ kPa}} = 1.2078 \text{ m}^3/\text{kg}$$

Thus,

$$\Delta v = v_2 - v_1 = 1.2078 - 1.1480 = \mathbf{0.0598 \text{ m}^3/\text{kg}}$$

The two results are identical.

12-10 Using the equation of state $P(\nu - a) = RT$, the cyclic relation, and the reciprocity relation at constant ν are to be verified.

Analysis (a) This equation of state involves three variables P , ν , and T . Any two of these can be taken as the independent variables, with the remaining one being the dependent variable. Replacing x , y , and z by P , ν , and T , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu = -1$$

where

$$\begin{aligned} P &= \frac{RT}{\nu - a} \longrightarrow \left(\frac{\partial P}{\partial \nu}\right)_T = \frac{-RT}{(\nu - a)^2} = -\frac{P}{\nu - a} \\ \nu &= \frac{RT}{P} + a \longrightarrow \left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P} \\ T &= \frac{P(\nu - a)}{R} \longrightarrow \left(\frac{\partial T}{\partial P}\right)_\nu = \frac{\nu - a}{R} \end{aligned}$$

Substituting,

$$\left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu = \left(-\frac{P}{\nu - a}\right) \left(\frac{R}{P}\right) \left(\frac{\nu - a}{R}\right) = -1$$

which is the desired result.

(b) The reciprocity rule for this gas at $\nu = \text{constant}$ can be expressed as

$$\begin{aligned} \left(\frac{\partial P}{\partial T}\right)_\nu &= \frac{1}{(\partial T / \partial P)_\nu} \\ T &= \frac{P(\nu - a)}{R} \longrightarrow \left(\frac{\partial T}{\partial P}\right)_\nu = \frac{\nu - a}{R} \\ P &= \frac{RT}{\nu - a} \longrightarrow \left(\frac{\partial P}{\partial T}\right)_\nu = \frac{R}{\nu - a} \end{aligned}$$

We observe that the first differential is the inverse of the second one. Thus the proof is complete.

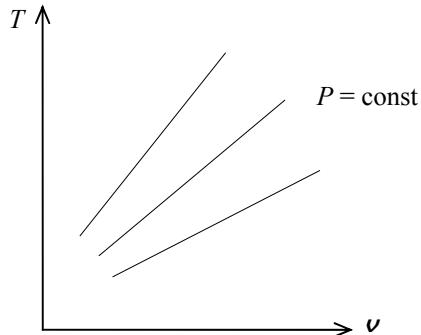

12-11 It is to be proven for an ideal gas that the $P = \text{constant}$ lines on a $T-\nu$ diagram are straight lines and that the high pressure lines are steeper than the low-pressure lines.

Analysis (a) For an ideal gas $P\nu = RT$ or $T = P\nu/R$. Taking the partial derivative of T with respect to ν holding P constant yields

$$\left(\frac{\partial T}{\partial \nu}\right)_P = \frac{P}{R}$$

which remains constant at $P = \text{constant}$. Thus the derivative $(\partial T/\partial \nu)_P$, which represents the slope of the $P = \text{const.}$ lines on a $T-\nu$ diagram, remains constant. That is, the $P = \text{const.}$ lines are straight lines on a $T-\nu$ diagram.

(b) The slope of the $P = \text{const.}$ lines on a $T-\nu$ diagram is equal to P/R , which is proportional to P . Therefore, the high pressure lines are steeper than low pressure lines on the $T-\nu$ diagram.

12-12 A relation is to be derived for the slope of the $\nu = \text{constant}$ lines on a $T-P$ diagram for a gas that obeys the van der Waals equation of state.

Analysis The van der Waals equation of state can be expressed as

$$T = \frac{1}{R} \left(P + \frac{a}{\nu^2} \right) (\nu - b)$$

Taking the derivative of T with respect to P holding ν constant,

$$\left(\frac{\partial T}{\partial P}\right)_\nu = \frac{1}{R} (1+0)(\nu - b) = \frac{\nu - b}{R}$$

which is the slope of the $\nu = \text{constant}$ lines on a $T-P$ diagram.

The Maxwell Relations

12-13 The validity of the last Maxwell relation for refrigerant-134a at a specified state is to be verified.

Analysis We do not have exact analytical property relations for refrigerant-134a, and thus we need to replace the differential quantities in the last Maxwell relation with the corresponding finite quantities. Using property values from the tables about the specified state,

$$\begin{aligned} \left(\frac{\partial s}{\partial P} \right)_T &\stackrel{?}{=} - \left(\frac{\partial v}{\partial T} \right)_P \\ \left(\frac{\Delta s}{\Delta P} \right)_{T=50^\circ C} &\stackrel{?}{\approx} - \left(\frac{\Delta v}{\Delta T} \right)_{P=700 \text{ kPa}} \\ \left(\frac{s_{900 \text{ kPa}} - s_{500 \text{ kPa}}}{(900 - 500) \text{ kPa}} \right)_{T=50^\circ C} &\stackrel{?}{\approx} - \left(\frac{v_{70^\circ C} - v_{30^\circ C}}{(70 - 30)^\circ C} \right)_{P=700 \text{ kPa}} \\ \frac{(0.9660 - 1.0309) \text{ kJ/kg} \cdot \text{K}}{(900 - 500) \text{ kPa}} &\stackrel{?}{\approx} - \frac{(0.036373 - 0.029966) \text{ m}^3/\text{kg}}{(70 - 30)^\circ C} \\ -1.621 \times 10^{-4} \text{ m}^3/\text{kg} \cdot \text{K} &\approx -1.602 \times 10^{-4} \text{ m}^3/\text{kg} \cdot \text{K} \end{aligned}$$

since $\text{kJ} \equiv \text{kPa} \cdot \text{m}^3$, and $\text{K} \equiv {}^\circ\text{C}$ for temperature differences. Thus the last Maxwell relation is satisfied.

12-14 Problem 12-13 is reconsidered. The validity of the last Maxwell relation for refrigerant 134a at the specified state is to be verified.

Analysis The problem is solved using EES, and the solution is given below.

12-15E The validity of the last Maxwell relation for steam at a specified state is to be verified.

Analysis We do not have exact analytical property relations for steam, and thus we need to replace the differential quantities in the last Maxwell relation with the corresponding finite quantities. Using property values from the tables about the specified state,

$$\begin{aligned} \left(\frac{\partial s}{\partial P} \right)_T &\stackrel{?}{=} - \left(\frac{\partial v}{\partial T} \right)_P \\ \left(\frac{\Delta s}{\Delta P} \right)_{T=800^{\circ}\text{F}} &\stackrel{?}{=} - \left(\frac{\Delta v}{\Delta T} \right)_{P=400\text{psia}} \\ \left(\frac{s_{450\text{ psia}} - s_{350\text{ psia}}}{(450 - 350)\text{psia}} \right)_{T=800^{\circ}\text{F}} &\stackrel{?}{\cong} - \left(\frac{v_{900^{\circ}\text{F}} - v_{700^{\circ}\text{F}}}{(900 - 700)^{\circ}\text{F}} \right)_{P=400\text{psia}} \\ \frac{(1.6706 - 1.7009)\text{Btu/lbm}\cdot\text{R}}{(450 - 350)\text{psia}} &\stackrel{?}{\cong} - \frac{(1.9777 - 1.6507)\text{ft}^3/\text{lbfm}}{(900 - 700)^{\circ}\text{F}} \\ -1.639 \times 10^{-3} \text{ ft}^3/\text{lbfm}\cdot\text{R} &\cong -1.635 \times 10^{-3} \text{ ft}^3/\text{lbfm}\cdot\text{R} \end{aligned}$$

since $1 \text{ Btu} \equiv 5.4039 \text{ psia}\cdot\text{ft}^3$, and $\text{R} \equiv {}^{\circ}\text{F}$ for temperature differences. Thus the fourth Maxwell relation is satisfied.

12-16 Using the Maxwell relations, a relation for $(\partial s / \partial P)_T$ for a gas whose equation of state is $P(v-b) = RT$ is to be obtained.

Analysis This equation of state can be expressed as $v = \frac{RT}{P} + b$. Then,

$$\left(\frac{\partial v}{\partial T} \right)_P = \frac{R}{P}$$

From the fourth Maxwell relation,

$$\left(\frac{\partial s}{\partial P} \right)_T = - \left(\frac{\partial v}{\partial T} \right)_P = - \frac{R}{P}$$

12-17 Using the Maxwell relations, a relation for $(\partial s / \partial v)_T$ for a gas whose equation of state is $(P-a/v^2)(v-b) = RT$ is to be obtained.

Analysis This equation of state can be expressed as $P = \frac{RT}{v-b} + \frac{a}{v^2}$. Then,

$$\left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b}$$

From the third Maxwell relation,

$$\left(\frac{\partial s}{\partial v} \right)_T = \left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b}$$

12-18 Using the Maxwell relations and the ideal-gas equation of state, a relation for $(\partial s/\partial v)_T$ for an ideal gas is to be obtained.

Analysis The ideal gas equation of state can be expressed as $P = \frac{RT}{v}$. Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v}$$

From the third Maxwell relation,

$$\left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v}$$

12-19 It is to be proven that $\left(\frac{\partial P}{\partial T}\right)_s = \frac{k}{k-1} \left(\frac{\partial P}{\partial T}\right)_v$

Analysis Using the definition of c_v ,

$$c_v = T \left(\frac{\partial s}{\partial T} \right)_v = T \left(\frac{\partial s}{\partial P} \right)_v \left(\frac{\partial P}{\partial T} \right)_v$$

Substituting the first Maxwell relation $\left(\frac{\partial s}{\partial P} \right)_v = - \left(\frac{\partial v}{\partial T} \right)_s$,

$$c_v = -T \left(\frac{\partial v}{\partial T} \right)_s \left(\frac{\partial P}{\partial T} \right)_v$$

Using the definition of c_p ,

$$c_p = T \left(\frac{\partial s}{\partial T} \right)_P = T \left(\frac{\partial s}{\partial v} \right)_P \left(\frac{\partial v}{\partial T} \right)_P$$

Substituting the second Maxwell relation $\left(\frac{\partial s}{\partial v} \right)_P = \left(\frac{\partial P}{\partial T} \right)_s$,

$$c_p = T \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial v}{\partial T} \right)_P$$

From Eq. 12-46,

$$c_p - c_v = -T \left(\frac{\partial v}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial v} \right)_T$$

Also,

$$\frac{k}{k-1} = \frac{c_p}{c_p - c_v}$$

Then,

$$\frac{k}{k-1} = - \frac{\left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial v}{\partial T} \right)_P}{\left(\frac{\partial v}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial v} \right)_T} = - \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial T}{\partial v} \right)_P \left(\frac{\partial v}{\partial P} \right)_T$$

Substituting this into the original equation in the problem statement produces

$$\left(\frac{\partial P}{\partial T} \right)_s = - \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial T}{\partial v} \right)_P \left(\frac{\partial v}{\partial P} \right)_T \left(\frac{\partial P}{\partial T} \right)_v$$

But, according to the cyclic relation, the last three terms are equal to -1 . Then,

$$\left(\frac{\partial P}{\partial T} \right)_s = \left(\frac{\partial P}{\partial T} \right)_s$$

12-20 It is to be shown how T , ν , u , a , and g could be evaluated from the thermodynamic function $h = h(s, P)$.

Analysis Forming the differential of the given expression for h produces

$$dh = \left(\frac{\partial h}{\partial s} \right)_P ds + \left(\frac{\partial h}{\partial P} \right)_s dP$$

Solving the dh Gibbs equation gives

$$dh = Tds + \nu dP$$

Comparing the coefficient of these two expressions

$$T = \left(\frac{\partial h}{\partial s} \right)_P$$

$$\nu = \left(\frac{\partial h}{\partial P} \right)_s$$

both of which can be evaluated for a given P and s .

From the definition of the enthalpy,

$$u = h - P\nu = h - P \left(\frac{\partial h}{\partial P} \right)_s$$

Similarly, the definition of the Helmholtz function,

$$a = u - Ts = h - P \left(\frac{\partial h}{\partial P} \right)_s - s \left(\frac{\partial h}{\partial s} \right)_P$$

while the definition of the Gibbs function gives

$$q = h - Ts = h - s \left(\frac{\partial h}{\partial s} \right)_P$$

All of these can be evaluated for a given P and s and the fundamental $h(s, P)$ equation.

The Clapeyron Equation

12-21C It enables us to determine the enthalpy of vaporization from h_{fg} at a given temperature from the P, v, T data alone.

12-22C It is assumed that $\nu_{fg} \approx \nu_g \approx RT/P$, and $h_{fg} \approx \text{constant}$ for small temperature intervals.

12-23 Using the Clapeyron equation, the enthalpy of vaporization of steam at a specified pressure is to be estimated and to be compared to the tabulated data.

Analysis From the Clapeyron equation,

$$\begin{aligned} h_{fg} &= T\nu_{fg}\left(\frac{dP}{dT}\right)_{\text{sat}} \\ &\approx T(\nu_g - \nu_f)_{@300 \text{ kPa}} \left(\frac{\Delta P}{\Delta T}\right)_{\text{sat, } 300 \text{ kPa}} \\ &= T_{\text{sat}@300 \text{ kPa}} (\nu_g - \nu_f)_{@300 \text{ kPa}} \left(\frac{(325 - 275) \text{ kPa}}{T_{\text{sat}@325 \text{ kPa}} - T_{\text{sat}@275 \text{ kPa}}} \right) \\ &= (133.52 + 273.15 \text{ K})(0.60582 - 0.001073 \text{ m}^3/\text{kg}) \left(\frac{50 \text{ kPa}}{(136.27 - 130.58)^\circ\text{C}} \right) \\ &= \mathbf{2159.9 \text{ kJ/kg}} \end{aligned}$$

The tabulated value of h_{fg} at 300 kPa is **2163.5 kJ/kg**.

12-24 The h_{fg} and s_{fg} of steam at a specified temperature are to be calculated using the Clapeyron equation and to be compared to the tabulated data.

Analysis From the Clapeyron equation,

$$\begin{aligned} h_{fg} &= T\nu_{fg}\left(\frac{dP}{dT}\right)_{\text{sat}} \\ &\approx T(\nu_g - \nu_f)_{@120^\circ\text{C}} \left(\frac{\Delta P}{\Delta T}\right)_{\text{sat, } 120^\circ\text{C}} \\ &= T(\nu_g - \nu_f)_{@120^\circ\text{C}} \left(\frac{P_{\text{sat}@125^\circ\text{C}} - P_{\text{sat}@115^\circ\text{C}}}{125^\circ\text{C} - 115^\circ\text{C}} \right) \\ &= (120 + 273.15 \text{ K})(0.89133 - 0.001060 \text{ m}^3/\text{kg}) \left(\frac{(232.23 - 169.18) \text{ kPa}}{10 \text{ K}} \right) \\ &= \mathbf{2206.8 \text{ kJ/kg}} \end{aligned}$$

Also, $s_{fg} = \frac{h_{fg}}{T} = \frac{2206.8 \text{ kJ/kg}}{(120 + 273.15) \text{ K}} = \mathbf{5.6131 \text{ kJ/kg}\cdot\text{K}}$

The tabulated values at 120°C are $h_{fg} = \mathbf{2202.1 \text{ kJ/kg}}$ and $s_{fg} = \mathbf{5.6013 \text{ kJ/kg}\cdot\text{K}}$.

12-25E The h_{fg} of refrigerant-134a at a specified temperature is to be calculated using the Clapeyron equation and Clapeyron-Clausius equation and to be compared to the tabulated data.

Analysis (a) From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T \nu_{fg} \left(\frac{dP}{dT} \right)_{\text{sat}} \\
 &\equiv T(\nu_g - \nu_f)_{@ 10^\circ\text{F}} \left(\frac{\Delta P}{\Delta T} \right)_{\text{sat}, 10^\circ\text{F}} \\
 &= T(\nu_g - \nu_f)_{@ 10^\circ\text{F}} \left(\frac{P_{\text{sat}@15^\circ\text{F}} - P_{\text{sat}@5^\circ\text{F}}}{15^\circ\text{F} - 5^\circ\text{F}} \right) \\
 &= (10 + 459.67 \text{ R})(1.7345 - 0.01201 \text{ ft}^3/\text{lbm}) \left(\frac{(29.759 - 23.793) \text{ psia}}{10 \text{ R}} \right) \\
 &= 482.6 \text{ psia} \cdot \text{ft}^3/\text{lbm} = \mathbf{89.31 \text{ Btu/lbm}} \quad (0.1\% \text{ error})
 \end{aligned}$$

since $1 \text{ Btu} = 5.4039 \text{ psia} \cdot \text{ft}^3$.

(b) From the Clapeyron-Clausius equation,

$$\begin{aligned}
 \ln \left(\frac{P_2}{P_1} \right)_{\text{sat}} &\equiv \frac{h_{fg}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)_{\text{sat}} \\
 \ln \left(\frac{23.793 \text{ psia}}{29.759 \text{ psia}} \right) &\equiv \frac{h_{fg}}{0.01946 \text{ Btu/lbm} \cdot \text{R}} \left(\frac{1}{15 + 459.67 \text{ R}} - \frac{1}{5 + 459.67 \text{ R}} \right) \\
 h_{fg} &= \mathbf{96.04 \text{ Btu/lbm}} \quad (7.6\% \text{ error})
 \end{aligned}$$

The tabulated value of h_{fg} at 10°F is **89.23 Btu/lbm**.

12-26 The enthalpy of vaporization of steam as a function of temperature using Clapeyron equation and steam data in EES is to be plotted.

Analysis The enthalpy of vaporization is determined using Clapeyron equation from

$$h_{fg,\text{Clapeyron}} = T \nu_{fg} \frac{\Delta P}{\Delta T}$$

At 100°C, for an increment of 5°C, we obtain

$$T_1 = T - T_{\text{increment}} = 100 - 5 = 95^\circ\text{C}$$

$$T_2 = T + T_{\text{increment}} = 100 + 5 = 105^\circ\text{C}$$

$$P_1 = P_{\text{sat@ } 95^\circ\text{C}} = 84.61 \text{ kPa}$$

$$P_2 = P_{\text{sat@ } 105^\circ\text{C}} = 120.90 \text{ kPa}$$

$$\Delta T = T_2 - T_1 = 105 - 95 = 10^\circ\text{C}$$

$$\Delta P = P_2 - P_1 = 120.90 - 84.61 = 36.29 \text{ kPa}$$

$$\nu_{f@100^\circ\text{C}} = 0.001043 \text{ m}^3/\text{kg}$$

$$\nu_{g@100^\circ\text{C}} = 1.6720 \text{ m}^3/\text{kg}$$

$$\nu_{fg} = \nu_g - \nu_f = 1.6720 - 0.001043 = 1.6710 \text{ m}^3/\text{kg}$$

Substituting,

$$h_{fg,\text{Clapeyron}} = T \nu_{fg} \frac{\Delta P}{\Delta T} = (100 + 273.15 \text{ K})(1.6710 \text{ m}^3/\text{kg}) \frac{36.29 \text{ kPa}}{10 \text{ K}} = \mathbf{2262.8 \text{ kJ/kg}}$$

The enthalpy of vaporization from steam table is

$$h_{fg@100^\circ\text{C}} = \mathbf{2256.4 \text{ m}^3/\text{kg}}$$

The percent error in using Clapeyron equation is

$$\text{PercentError} = \frac{2262.8 - 2256.4}{2256.4} \times 100 = \mathbf{0.28\%}$$

We repeat the analysis over the temperature range 10 to 200°C using EES. Below, the copy of EES solution is provided:

```
"Input Data:"
{T=100" "[C]"
T_increment = 5"[C]"
T[2]=T+T_increment"[C]"
T[1]=T-T_increment"[C]"

12-27E A substance is cooled in a piston-cylinder device until it turns from saturated vapor to saturated liquid at a constant pressure and temperature. The boiling temperature of this substance at a different pressure is to be estimated.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{(250 \text{ Btu}) \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) / (0.5 \text{ lbm})}{(475 \text{ R})(1.5 \text{ ft}^3) / (0.5 \text{ lbm})} = 1.896 \text{ psia/R}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for T_2 ,

$$T_2 = T_1 + \frac{P_2 - P_1}{dP/dT} = 475 \text{ R} + \frac{(60 - 50) \text{ psia}}{1.896 \text{ psia/R}} = 480.3 \text{ R}$$

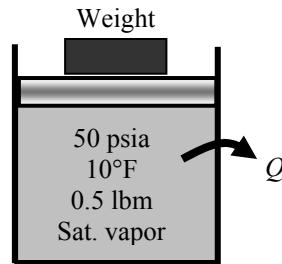

12-28E A substance is cooled in a piston-cylinder device until it turns from saturated vapor to saturated liquid at a constant pressure and temperature. The saturation pressure of this substance at a different temperature is to be estimated.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{(250 \text{ Btu}) \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) / (0.5 \text{ lbm})}{(475 \text{ R})(1.5 \text{ ft}^3) / (0.5 \text{ lbm})} = 1.896 \text{ psia/R}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for P_2 ,

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 50 \text{ psia} + (1.896 \text{ psia/R})(470 - 475) \text{ R} = 40.52 \text{ psia}$$

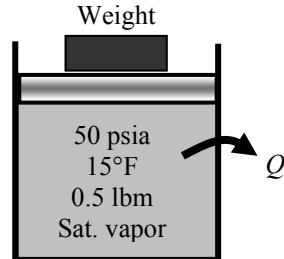

12-29E A substance is cooled in a piston-cylinder device until it turns from saturated vapor to saturated liquid at a constant pressure and temperature. The s_{fg} of this substance at the given temperature is to be estimated.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{s_{fg}}{\nu_{fg}}$$

Solving for s_{fg} ,

$$s_{fg} = \frac{h_{fg}}{T} = \frac{(250 \text{ Btu})/(0.5 \text{ lbm})}{475 \text{ R}} = \mathbf{1.053 \text{ Btu/lbm} \cdot \text{R}}$$

Alternatively,

$$s_{fg} = \left(\frac{dP}{dT}\right)_{\text{sat}} \nu_{fg} = (1.896 \text{ psia/R}) \frac{1.5 \text{ ft}^3}{0.5 \text{ lbm}} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) = 1.053 \text{ Btu/lbm} \cdot \text{R}$$

12-30E Saturation properties for R-134a at a specified temperature are given. The saturation pressure is to be estimated at two different temperatures.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{90.886 \text{ Btu/lbm}}{(460 \text{ R})(2.1446 \text{ ft}^3/\text{lbm})} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) = 0.4979 \text{ psia/R}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1} \right)_{\text{sat}}$$

Solving for P_2 at -15°F

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 21.185 \text{ psia} + (0.4979 \text{ psia/R})(445 - 460) \text{ R} = \mathbf{13.72 \text{ psia}}$$

Solving for P_2 at -30°F

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 21.185 \text{ psia} + (0.4979 \text{ psia/R})(430 - 460) \text{ R} = \mathbf{6.25 \text{ psia}}$$

12-31E A table of properties for methyl chloride is given. The saturation pressure is to be estimated at two different temperatures.

Analysis The Clapeyron equation is

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

Solving this for the second pressure gives for $T_2 = 110^{\circ}\text{F}$

$$\begin{aligned} P_2 &= P_1 + \frac{h_{fg}}{T\nu_{fg}}(T_2 - T_1) \\ &= 116.7 \text{ psia} + \frac{154.85 \text{ Btu/lbm}}{(560 \text{ R})(0.86332 \text{ ft}^3/\text{lbm})} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) (110 - 100) \text{ R} \\ &= \mathbf{134.0 \text{ psia}} \end{aligned}$$

When $T_2 = 90^{\circ}\text{F}$

$$\begin{aligned} P_2 &= P_1 + \frac{h_{fg}}{T\nu_{fg}}(T_2 - T_1) \\ &= 116.7 \text{ psia} + \frac{154.85 \text{ Btu/lbm}}{(560 \text{ R})(0.86332 \text{ ft}^3/\text{lbm})} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) (90 - 100) \text{ R} \\ &= \mathbf{99.4 \text{ psia}} \end{aligned}$$

12-32 It is to be shown that $c_{p,g} - c_{p,f} = T \left(\frac{\partial(h_{fg}/T)}{\partial T} \right)_P + \nu_{fg} \left(\frac{\partial P}{\partial T} \right)_{\text{sat}}$.

Analysis The definition of specific heat and Clapeyron equation are

$$c_p = \left(\frac{\partial h}{\partial T} \right)_P$$

$$\left(\frac{dP}{dT} \right)_{\text{sat}} = \frac{h_{fg}}{T \nu_{fg}}$$

According to the definition of the enthalpy of vaporization,

$$\frac{h_{fg}}{T} = \frac{h_g}{T} - \frac{h_f}{T}$$

Differentiating this expression gives

$$\begin{aligned} \left(\frac{\partial h_{fg}/T}{\partial T} \right)_P &= \left(\frac{\partial h_g/T}{\partial T} \right)_P - \left(\frac{\partial h_f/T}{\partial T} \right)_P \\ &= \frac{1}{T} \left(\frac{\partial h_g}{\partial T} \right)_P - \frac{h_g}{T^2} - \frac{1}{T} \left(\frac{\partial h_f}{\partial T} \right)_P + \frac{h_f}{T^2} \\ &= \frac{c_{p,g}}{T} - \frac{c_{p,f}}{T} - \frac{h_g - h_f}{T^2} \end{aligned}$$

Using Clasius-Clapeyron to replace the last term of this expression and solving for the specific heat difference gives

$$c_{p,g} - c_{p,f} = T \left(\frac{\partial(h_{fg}/T)}{\partial T} \right)_P + \nu_{fg} \left(\frac{\partial P}{\partial T} \right)_{\text{sat}}$$

General Relations for du , dh , ds , c_v , and c_p

12-33C Yes, through the relation

$$\left(\frac{\partial c_p}{\partial P}\right)_T = -T \left(\frac{\partial^2 \nu}{\partial T^2}\right)_P$$

12-34E The specific heat difference $c_p - c_v$ for liquid water at 1000 psia and 300°F is to be estimated.

Analysis The specific heat difference $c_p - c_v$ is given as

$$c_p - c_v = -T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial P}{\partial \nu}\right)_T$$

Approximating differentials by differences about the specified state,

$$\begin{aligned} c_p - c_v &\equiv -T \left(\frac{\Delta \nu}{\Delta T}\right)_{P=1000\text{psia}}^2 \left(\frac{\Delta P}{\Delta \nu}\right)_{T=300^\circ\text{F}} \\ &= -(300 + 459.67 \text{ R}) \left(\frac{\nu_{325^\circ\text{F}} - \nu_{275^\circ\text{F}}}{(325 - 275)^\circ\text{F}}\right)_{P=1000\text{psia}}^2 \left(\frac{(1500 - 500)\text{psia}}{\nu_{1500\text{psia}} - \nu_{500\text{psia}}}\right)_{T=300^\circ\text{F}} \\ &= -(609.67 \text{ R}) \left(\frac{(0.017633 - 0.017151)\text{ft}^3/\text{lbm}}{50 \text{ R}}\right)^2 \left(\frac{1000 \text{ psia}}{(0.017345 - 0.017417)\text{ft}^3/\text{lbm}}\right) \\ &= 0.986 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R} \\ &= \mathbf{0.183 \text{ Btu/lbm} \cdot \text{R}} \quad (1 \text{ Btu} = 5.4039 \text{ psia} \cdot \text{ft}^3) \end{aligned}$$

Properties are obtained from Table A-7E.

12-35 The volume expansivity β and the isothermal compressibility α of refrigerant-134a at 200 kPa and 30°C are to be estimated.

Analysis The volume expansivity and isothermal compressibility are expressed as

$$\beta = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T} \right)_P \quad \text{and} \quad \alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T$$

Approximating differentials by differences about the specified state,

$$\begin{aligned}\beta &\equiv \frac{1}{\nu} \left(\frac{\Delta \nu}{\Delta T} \right)_{P=200\text{kPa}} = \frac{1}{\nu} \left(\frac{\nu_{40^\circ\text{C}} - \nu_{20^\circ\text{C}}}{(40 - 20)^\circ\text{C}} \right)_{P=200\text{kPa}} \\ &= \frac{1}{0.11874 \text{ m}^3/\text{kg}} \left(\frac{(0.12322 - 0.11418)\text{m}^3/\text{kg}}{20 \text{ K}} \right) \\ &= \mathbf{0.00381 \text{ K}^{-1}}\end{aligned}$$

and

$$\begin{aligned}\alpha &\equiv -\frac{1}{\nu} \left(\frac{\Delta \nu}{\Delta P} \right)_{T=30^\circ\text{C}} = -\frac{1}{\nu} \left(\frac{\nu_{240\text{kPa}} - \nu_{180\text{kPa}}}{(240 - 180)\text{kPa}} \right)_{T=30^\circ\text{C}} \\ &= -\frac{1}{0.11874 \text{ m}^3/\text{kg}} \left(\frac{(0.09812 - 0.13248)\text{m}^3/\text{kg}}{60 \text{ kPa}} \right) \\ &= \mathbf{0.00482 \text{ kPa}^{-1}}\end{aligned}$$

12-36 The internal energy change of air between two specified states is to be compared for two equations of states.

Assumptions Constant specific heats for air can be used.

Properties For air at the average temperature $(20+300)/2=160^{\circ}\text{C}=433\text{ K}$, $c_v=0.731\text{ kJ/kg}\cdot\text{K}$ (Table A-2b).

Analysis Solving the equation of state for P gives

$$P = \frac{RT}{v-a}$$

Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v-a}$$

Using equation 12-29,

$$du = c_v dT + \left[T \left(\frac{\partial P}{\partial T} \right)_v - P \right] dv$$

Substituting,

$$\begin{aligned} du &= c_v dT + \left(\frac{RT}{v-a} - \frac{RT}{v-a} \right) dv \\ &= c_v dT \end{aligned}$$

Integrating this result between the two states with constant specific heats gives

$$u_2 - u_1 = c_v (T_2 - T_1) = (0.731\text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{205\text{ kJ/kg}}$$

The ideal gas model for the air gives

$$du = c_v dT$$

which gives the same answer.

12-37 The enthalpy change of air between two specified states is to be compared for two equations of states.

Assumptions Constant specific heats for air can be used.

Properties For air at the average temperature $(20+300)/2=160^{\circ}\text{C}=433\text{ K}$, $c_p = 1.018 \text{ kJ/kg}\cdot\text{K}$ (Table A-2b).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

Using equation 12-35,

$$dh = c_p dT + \left[\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P \right] dP$$

Substituting,

$$\begin{aligned} dh &= c_p dT + \left(\frac{RT}{P} + a - \frac{RT}{P} \right) dP \\ &= c_p dT + adP \end{aligned}$$

Integrating this result between the two states with constant specific heats gives

$$\begin{aligned} h_2 - h_1 &= c_p (T_2 - T_1) + a(P_2 - P_1) \\ &= (1.018 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} + (0.01 \text{ m}^3/\text{kg})(600 - 100)\text{kPa} \\ &= \mathbf{290.0 \text{ kJ/kg}} \end{aligned}$$

For an ideal gas,

$$dh = c_p dT$$

which when integrated gives

$$h_2 - h_1 = c_p (T_2 - T_1) = (1.018 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{285.0 \text{ kJ/kg}}$$

12-38 The entropy change of air between two specified states is to be compared for two equations of states.

Assumptions Constant specific heats for air can be used.

Properties For air at the average temperature $(20+300)/2=160^{\circ}\text{C}=433\text{ K}$, $c_p = 1.018\text{ kJ/kg}\cdot\text{K}$ (Table A-2b) and $R = 0.287\text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The entropy differential is

$$\begin{aligned} ds &= c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP \\ &= c_p \frac{dT}{T} - R \frac{dP}{P} \end{aligned}$$

which is the same as that of an ideal gas. Integrating this result between the two states with constant specific heats gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.018\text{ kJ/kg}\cdot\text{K}) \ln \frac{573\text{ K}}{293\text{ K}} - (0.287\text{ kJ/kg}\cdot\text{K}) \ln \frac{600\text{ kPa}}{100\text{ kPa}} \\ &= \mathbf{0.1686\text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

12-39 The internal energy change of helium between two specified states is to be compared for two equations of states.

Properties For helium, $c_v = 3.1156 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Solving the equation of state for P gives

$$P = \frac{RT}{v - a}$$

Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v - a}$$

Using equation 12-29,

$$du = c_v dT + \left[T \left(\frac{\partial P}{\partial T} \right)_v - P \right] dv$$

Substituting,

$$\begin{aligned} du &= c_v dT + \left(\frac{RT}{v-a} - \frac{RT}{v-a} \right) dv \\ &= c_v dT \end{aligned}$$

Integrating this result between the two states gives

$$u_2 - u_1 = c_v (T_2 - T_1) = (3.1156 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{872.4 \text{ kJ/kg}}$$

The ideal gas model for the helium gives

$$du = c_v dT$$

which gives the same answer.

12-40 The enthalpy change of helium between two specified states is to be compared for two equations of states.

Properties For helium, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

Using equation 12-35,

$$dh = c_p dT + \left[\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P \right] dP$$

Substituting,

$$\begin{aligned} dh &= c_p dT + \left(\frac{RT}{P} + a - \frac{RT}{P} \right) dP \\ &= c_p dT + adP \end{aligned}$$

Integrating this result between the two states gives

$$\begin{aligned} h_2 - h_1 &= c_p (T_2 - T_1) + a(P_2 - P_1) \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} + (0.01 \text{ m}^3/\text{kg})(600 - 100)\text{kPa} \\ &= \mathbf{1459 \text{ kJ/kg}} \end{aligned}$$

For an ideal gas,

$$dh = c_p dT$$

which when integrated gives

$$h_2 - h_1 = c_p (T_2 - T_1) = (5.1926 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{1454 \text{ kJ/kg}}$$

12-41 The entropy change of helium between two specified states is to be compared for two equations of states.

Properties For helium, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The entropy differential is

$$\begin{aligned} ds &= c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP \\ &= c_p \frac{dT}{T} - R \frac{dP}{P} \end{aligned}$$

which is the same as that of an ideal gas. Integrating this result between the two states gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K}) \ln \frac{573 \text{ K}}{293 \text{ K}} - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln \frac{600 \text{ kPa}}{100 \text{ kPa}} \\ &= \mathbf{-0.2386 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

12-42 General expressions for Δu , Δh , and Δs for a gas whose equation of state is $P(\nu-a) = RT$ for an isothermal process are to be derived.

Analysis (a) A relation for Δu is obtained from the general relation

$$\Delta u = u_2 - u_1 = \int_{T_1}^{T_2} c_v dT + \int_{\nu_1}^{\nu_2} \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) d\nu$$

The equation of state for the specified gas can be expressed as

$$P = \frac{RT}{\nu - a} \longrightarrow \left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{\nu - a}$$

Thus,

$$T \left(\frac{\partial P}{\partial T} \right)_v - P = \frac{RT}{\nu - a} - P = P - P = 0$$

$$\text{Substituting, } \Delta u = \int_{T_1}^{T_2} c_v dT$$

(b) A relation for Δh is obtained from the general relation

$$\Delta h = h_2 - h_1 = \int_{T_1}^{T_2} c_p dT + \int_{P_1}^{P_2} \left(\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P \right) dP$$

The equation of state for the specified gas can be expressed as

$$\nu = \frac{RT}{P} + a \longrightarrow \left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

Thus,

$$\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P = \nu - T \frac{R}{P} = \nu - (\nu - a) = a$$

Substituting,

$$\Delta h = \int_{T_1}^{T_2} c_p dT + \int_{P_1}^{P_2} adP = \int_{T_1}^{T_2} c_p dT + a(P_2 - P_1)$$

(c) A relation for Δs is obtained from the general relation

$$\Delta s = s_2 - s_1 = \int_{T_1}^{T_2} \frac{c_p}{T} dT - \int_{P_1}^{P_2} \left(\frac{\partial \nu}{\partial T} \right)_P dP$$

Substituting $(\partial \nu / \partial T)_P = R/T$,

$$\Delta s = \int_{T_1}^{T_2} \frac{c_p}{T} dT - \int_{P_1}^{P_2} \left(\frac{R}{P} \right)_P dP = \int_{T_1}^{T_2} \frac{c_p}{T} dT - R \ln \frac{P_2}{P_1}$$

For an isothermal process $dT = 0$ and these relations reduce to

$$\Delta u = 0, \quad \Delta h = a(P_2 - P_1), \quad \text{and} \quad \Delta s = -R \ln \frac{P_2}{P_1}$$

12-43 General expressions for $(\partial u / \partial P)_T$ and $(\partial h / \partial v)_T$ in terms of P , v , and T only are to be derived.

Analysis The general relation for du is

$$du = c_v dT + \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) dv$$

Differentiating each term in this equation with respect to P at $T = \text{constant}$ yields

$$\left(\frac{\partial u}{\partial P} \right)_T = 0 + \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) \left(\frac{\partial v}{\partial P} \right)_T = T \left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial v}{\partial P} \right)_T - P \left(\frac{\partial v}{\partial P} \right)_T$$

Using the properties P , T , v , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial T}{\partial v} \right)_P \left(\frac{\partial v}{\partial P} \right)_T = -1 \longrightarrow \left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial v}{\partial P} \right)_T = - \left(\frac{\partial v}{\partial T} \right)_P$$

Substituting, we get

$$\left(\frac{\partial u}{\partial P} \right)_T = -T \left(\frac{\partial v}{\partial T} \right)_P - P \left(\frac{\partial v}{\partial P} \right)_T$$

The general relation for dh is

$$dh = c_p dT + \left(v - T \left(\frac{\partial v}{\partial T} \right)_P \right) dP$$

Differentiating each term in this equation with respect to v at $T = \text{constant}$ yields

$$\left(\frac{\partial h}{\partial v} \right)_T = 0 + \left(v - T \left(\frac{\partial v}{\partial T} \right)_P \right) \left(\frac{\partial P}{\partial v} \right)_T = v \left(\frac{\partial P}{\partial v} \right)_T - T \left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T$$

Using the properties v , T , P , the cyclic relation can be expressed as

$$\left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial T}{\partial P} \right)_v \left(\frac{\partial P}{\partial v} \right)_T = -1 \longrightarrow \left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T = - \left(\frac{\partial T}{\partial P} \right)_v$$

Substituting, we get

$$\left(\frac{\partial h}{\partial v} \right)_T = v \left(\frac{\partial P}{\partial v} \right)_T + T \left(\frac{\partial T}{\partial P} \right)_v$$

12-44 It is to be shown that $c_p - c_v = T \left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial v}{\partial T} \right)_P$.

Analysis We begin by taking the entropy to be a function of specific volume and temperature. The differential of the entropy is then

$$ds = \left(\frac{\partial s}{\partial T} \right)_v dT + \left(\frac{\partial s}{\partial v} \right)_T dv$$

Substituting $\left(\frac{\partial s}{\partial T} \right)_v = \frac{c_v}{T}$ from Eq. 12-28 and the third Maxwell equation changes this to

$$ds = \frac{c_v}{T} dT + \left(\frac{\partial P}{\partial T} \right)_v dv$$

Taking the entropy to be a function of pressure and temperature,

$$ds = \left(\frac{\partial s}{\partial T} \right)_P dT + \left(\frac{\partial s}{\partial P} \right)_T dP$$

Combining this result with $\left(\frac{\partial s}{\partial T} \right)_P = \frac{c_p}{T}$ from Eq. 12-34 and the fourth Maxwell equation produces

$$ds = \frac{c_p}{T} dT - \left(\frac{\partial v}{\partial T} \right)_P dP$$

Equating the two previous ds expressions and solving the result for the specific heat difference,

$$(c_p - c_v) dT = T \left(\frac{\partial v}{\partial T} \right)_P dP + \left(\frac{\partial P}{\partial T} \right)_v dv$$

Taking the pressure to be a function of temperature and volume,

$$dP = \left(\frac{\partial P}{\partial T} \right)_v dT + \left(\frac{\partial P}{\partial v} \right)_T dv$$

When this is substituted into the previous expression, the result is

$$(c_p - c_v) dT = T \left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial T} \right)_v dT + T \left[\left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T \left(\frac{\partial P}{\partial T} \right)_v \right] dv$$

According to the cyclic relation, the term in the bracket is zero. Then, canceling the common dT term,

$$c_p - c_v = T \left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial v}{\partial T} \right)_P$$

12-45 It is to be proven that the definition for temperature $T = (\partial u / \partial s)_v$ reduces the net entropy change of two constant-volume systems filled with simple compressible substances to zero as the two systems approach thermal equilibrium.

Analysis The two constant-volume systems form an isolated system shown here

For the isolated system

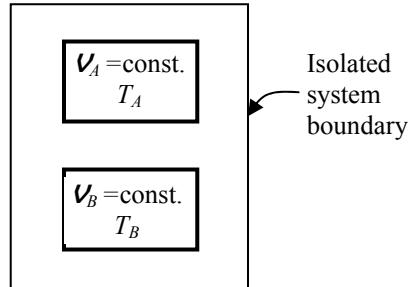

$$dS_{\text{tot}} = dS_A + dS_B \geq 0$$

Assume $S = S(u, v)$

Then,

$$ds = \left(\frac{\partial s}{\partial u} \right)_v du + \left(\frac{\partial s}{\partial v} \right)_u d\nu$$

Since $\nu = \text{const.}$ and $d\nu = 0$,

$$ds = \left(\frac{\partial s}{\partial u} \right)_v du$$

and from the definition of temperature from the problem statement,

$$\frac{du}{(\partial u / \partial s)_v} = \frac{du}{T}$$

Then,

$$dS_{\text{tot}} = m_A \frac{du_A}{T_A} + m_B \frac{du_B}{T_B}$$

The first law applied to the isolated system yields

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= dU \\ 0 = dU &\longrightarrow m_A du_A + m_B du_B = 0 \longrightarrow m_B du_B = -m_A du_A \end{aligned}$$

Now, the entropy change may be expressed as

$$dS_{\text{tot}} = m_A du_A \left(\frac{1}{T_A} - \frac{1}{T_B} \right) = m_A du_A \left(\frac{T_B - T_A}{T_A T_B} \right)$$

As the two systems approach thermal equilibrium,

$$\begin{aligned} \lim dS_{\text{tot}} &= 0 \\ T_A \rightarrow T_B & \end{aligned}$$

12-46 An expression for the volume expansivity of a substance whose equation of state is $P(\nu - a) = RT$ is to be derived.

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

The specific volume derivative is then

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

The definition for volume expansivity is

$$\beta = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T} \right)_P$$

Combining these two equations gives

$$\beta = \frac{R}{RT + aP}$$

12-47 An expression for the specific heat difference of a substance whose equation of state is $P(\nu - a) = RT$ is to be derived.

Analysis The specific heat difference is expressed by

$$c_p - c_v = -T \left(\frac{\partial \nu}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial \nu} \right)_T$$

Solving the equation of state for specific volume,

$$\nu = \frac{RT}{P} + a$$

The specific volume derivatives are then

$$\left(\frac{\partial \nu}{\partial P} \right)_T = -\frac{RT}{P^2} \longrightarrow \left(\frac{\partial P}{\partial \nu} \right)_T = -\frac{P^2}{RT}$$

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

Substituting,

$$c_p - c_v = -T \left(\frac{R}{P} \right)^2 \left(-\frac{P^2}{RT} \right) = -T \left(\frac{R^2}{P^2} \right) \left(-\frac{P^2}{RT} \right) = R$$

12-48 An expression for the isothermal compressibility of a substance whose equation of state is $P(\nu - a) = RT$ is to be derived.

Analysis The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T$$

Solving the equation of state for specific volume,

$$\nu = \frac{RT}{P} + a$$

The specific volume derivative is then

$$\left(\frac{\partial \nu}{\partial P} \right)_T = -\frac{RT}{P^2}$$

Substituting these into the isothermal compressibility equation gives

$$\alpha = \frac{RT}{P^2} \left(\frac{P}{RT + aP} \right) = \frac{RT}{P(RT + aP)}$$

12-49 An expression for the isothermal compressibility of a substance whose equation of state is $P = \frac{RT}{\nu - b} - \frac{a}{\nu(\nu + b)T^{1/2}}$

is to be derived.

Analysis The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T$$

The derivative is

$$\left(\frac{\partial P}{\partial \nu} \right)_T = -\frac{RT}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{\nu^2(\nu + b)^2}$$

Substituting,

$$\alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T = -\frac{1}{\nu} \left(\frac{1}{-\frac{RT}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{\nu^2(\nu + b)^2}} \right) = -\frac{1}{-\frac{RT\nu}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{(\nu + b)^2}}$$

12-50 An expression for the volume expansivity of a substance whose equation of state is $P = \frac{RT}{v-b} - \frac{a}{v(v+b)T^{1/2}}$ is to be derived.

Analysis The definition for volume expansivity is

$$\beta = \frac{1}{v} \left(\frac{\partial v}{\partial T} \right)_P$$

According to the cyclic relation,

$$\left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T \left(\frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left(\frac{\partial v}{\partial T} \right)_P = - \frac{\left(\frac{\partial P}{\partial T} \right)_v}{\left(\frac{\partial P}{\partial v} \right)_T}$$

Proceeding to perform the differentiations gives

$$\left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b} + \frac{a}{2v(v+b)T^{3/2}}$$

and

$$\begin{aligned} \left(\frac{\partial P}{\partial v} \right)_T &= -\frac{RT}{(v-b)^2} + \frac{a}{bT^{1/2}} \left[\frac{1}{v^2} - \frac{1}{(v+b)^2} \right] \\ &= -\frac{RT}{(v-b)^2} + \frac{a}{T^{1/2}} \frac{2v+b}{v^2(v+b)^2} \end{aligned}$$

Substituting these results into the definition of the volume expansivity produces

$$\beta = -\frac{1}{v} \frac{\frac{R}{v-b} + \frac{a}{2v(v+b)T^{3/2}}}{\frac{-RT}{(v-b)^2} + \frac{a}{T^{1/2}} \frac{2v+b}{v^2(v+b)^2}}$$

12-51 An expression for the volume expansivity of a substance whose equation of state is $P = \frac{RT}{v-b} - \frac{a}{v^2 T}$ is to be derived.

Analysis The definition for volume expansivity is

$$\beta = \frac{1}{v} \left(\frac{\partial v}{\partial T} \right)_P$$

According to the cyclic relation,

$$\left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T \left(\frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left(\frac{\partial v}{\partial T} \right)_P = - \frac{\left(\frac{\partial P}{\partial T} \right)_v}{\left(\frac{\partial P}{\partial v} \right)_T}$$

Proceeding to perform the differentiations gives

$$\left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b} + \frac{a}{v^2 T^2}$$

and

$$\left(\frac{\partial P}{\partial v} \right)_T = - \frac{RT}{(v-b)^2} + \frac{2a}{v^3 T}$$

Substituting these results into the definition of the volume expansivity produces

$$\beta = - \frac{1}{v} \frac{\frac{R}{v-b} + \frac{a}{v^2 T^2}}{\frac{-RT}{(v-b)^2} + \frac{2a}{v^3 T}}$$

12-52 It is to be shown that $\beta = \alpha \left(\frac{\partial P}{\partial T} \right)_v$.

Analysis The definition for the volume expansivity is

$$\beta = \frac{1}{v} \left(\frac{\partial v}{\partial T} \right)_P$$

The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{v} \left(\frac{\partial v}{\partial P} \right)_T$$

According to the cyclic relation,

$$\left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T \left(\frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left(\frac{\partial v}{\partial T} \right)_P = -\left(\frac{\partial v}{\partial P} \right)_T \left(\frac{\partial P}{\partial T} \right)_v$$

When this is substituted into the definition of the volume expansivity, the result is

$$\begin{aligned} \beta &= -\frac{1}{v} \left(\frac{\partial v}{\partial P} \right)_T \left(\frac{\partial P}{\partial T} \right)_v \\ &= -\alpha \left(\frac{\partial P}{\partial T} \right)_v \end{aligned}$$

12-53 It is to be demonstrated that $k = \frac{c_p}{c_v} = -\frac{\nu\alpha}{(\partial\nu/\partial P)_s}$.

Analysis The relations for entropy differential are

$$ds = c_v \frac{dT}{T} + \left(\frac{\partial P}{\partial T} \right)_v d\nu$$

$$ds = c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T} \right)_P dP$$

For fixed s , these basic equations reduce to

$$c_v \frac{dT}{T} = - \left(\frac{\partial P}{\partial T} \right)_v d\nu$$

$$c_p \frac{dT}{T} = \left(\frac{\partial \nu}{\partial T} \right)_P dP$$

Also, when s is fixed,

$$\frac{\partial \nu}{\partial P} = \left(\frac{\partial \nu}{\partial P} \right)_s$$

Forming the specific heat ratio from these expressions gives

$$k = - \frac{\left(\frac{\partial \nu}{\partial T} \right)_P \left(\frac{\partial T}{\partial P} \right)_\nu}{\left(\frac{\partial \nu}{\partial P} \right)_s}$$

The cyclic relation is

$$\left(\frac{\partial \nu}{\partial T} \right)_P \left(\frac{\partial P}{\partial \nu} \right)_T \left(\frac{\partial T}{\partial P} \right)_\nu = -1$$

Solving this for the numerator of the specific heat ratio expression and substituting the result into this numerator produces

$$k = \frac{\left(\frac{\partial \nu}{\partial P} \right)_T}{\left(\frac{\partial \nu}{\partial P} \right)_s} = - \frac{\nu\alpha}{\left(\frac{\partial \nu}{\partial P} \right)_s}$$

12-54 The Helmholtz function of a substance has the form $a = -RT \ln \frac{\nu}{\nu_0} - cT_0 \left(1 - \frac{T}{T_0} + \frac{T}{T_0} \ln \frac{T}{T_0}\right)$. It is to be shown how to obtain P , h , s , c_v , and c_p from this expression.

Analysis Taking the Helmholtz function to be a function of temperature and specific volume yields

$$da = \left(\frac{\partial a}{\partial T}\right)_v dT + \left(\frac{\partial a}{\partial \nu}\right)_T d\nu$$

while the applicable Helmholtz equation is

$$da = -Pd\nu - sdT$$

Equating the coefficients of the two results produces

$$P = -\left(\frac{\partial a}{\partial \nu}\right)_T$$

$$s = -\left(\frac{\partial a}{\partial T}\right)_v$$

Taking the indicated partial derivatives of the Helmholtz function given in the problem statement reduces these expressions to

$$P = \frac{RT}{\nu}$$

$$s = R \ln \frac{\nu}{\nu_0} + c \ln \frac{T}{T_0}$$

The definition of the enthalpy ($h = u + Pv$) and Helmholtz function ($a = u - Ts$) may be combined to give

$$\begin{aligned} h &= u + Pv \\ &= a + Ts + Pv \\ &= a - T\left(\frac{\partial a}{\partial T}\right)_v - \nu\left(\frac{\partial a}{\partial \nu}\right)_T \\ &= -RT \ln \frac{\nu}{\nu_0} - cT_0 \left(1 - \frac{T}{T_0} + \frac{T}{T_0} \ln \frac{T}{T_0}\right) + RT \ln \frac{\nu}{\nu_0} - cT \ln \frac{T}{T_0} + RT \\ &= cT_0 + cT + RT \end{aligned}$$

According to $\left(\frac{\partial s}{\partial T}\right)_v = \frac{c_v}{T}$ given in the text (Eq. 12-28),

$$c_v = T\left(\frac{\partial s}{\partial T}\right)_v = T \frac{c}{T} = c$$

The preceding expression for the temperature indicates that the equation of state for the substance is the same as that of an ideal gas. Then,

$$c_p = R + c_v = R + c$$

The Joule-Thomson Coefficient

12-55C It represents the variation of temperature with pressure during a throttling process.

12-56C The line that passes through the peak points of the constant enthalpy lines on a *T-P* diagram is called the inversion line. The maximum inversion temperature is the highest temperature a fluid can be cooled by throttling.

12-57C No. The temperature may even increase as a result of throttling.

12-58C Yes.

12-59C No. Helium is an ideal gas and $h = h(T)$ for ideal gases. Therefore, the temperature of an ideal gas remains constant during a throttling ($h = \text{constant}$) process.

12-60E  The Joule-Thomson coefficient of nitrogen at two states is to be estimated.

Analysis (a) The enthalpy of nitrogen at 120 psia and 350 R is, from EES, $h = 84.88 \text{ Btu/lbm}$. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \approx \left(\frac{\Delta T}{\Delta P} \right)_{h=84.88 \text{ Btu/lbm}}$$

Considering a throttling process from 130 psia to 110 psia at $h = 84.88 \text{ Btu/lbm}$, the Joule-Thomson coefficient is determined to be

$$\mu = \left(\frac{T_{110 \text{ psia}} - T_{130 \text{ psia}}}{(110 - 130) \text{ psia}} \right)_{h=84.88 \text{ Btu/lbm}} = \frac{(349.40 - 350.60) \text{ R}}{(110 - 130) \text{ psia}} = \mathbf{0.0599 \text{ R/psia}}$$

(b) The enthalpy of nitrogen at 1200 psia and 700 R is, from EES, $h = 170.14 \text{ Btu/lbm}$. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \approx \left(\frac{\Delta T}{\Delta P} \right)_{h=170.14 \text{ Btu/lbm}}$$

Considering a throttling process from 1210 psia to 1190 psia at $h = 170.14 \text{ Btu/lbm}$, the Joule-Thomson coefficient is determined to be

$$\mu = \left(\frac{T_{1190 \text{ psia}} - T_{1210 \text{ psia}}}{(1190 - 1210) \text{ psia}} \right)_{h=170.14 \text{ Btu/lbm}} = \frac{(699.91 - 700.09) \text{ R}}{(1190 - 1210) \text{ psia}} = \mathbf{0.00929 \text{ R/psia}}$$

12-61E Problem 12-60E is reconsidered. The Joule-Thompson coefficient for nitrogen over the pressure range 100 to 1500 psia at the enthalpy values 100, 175, and 225 Btu/lbm is to be plotted.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

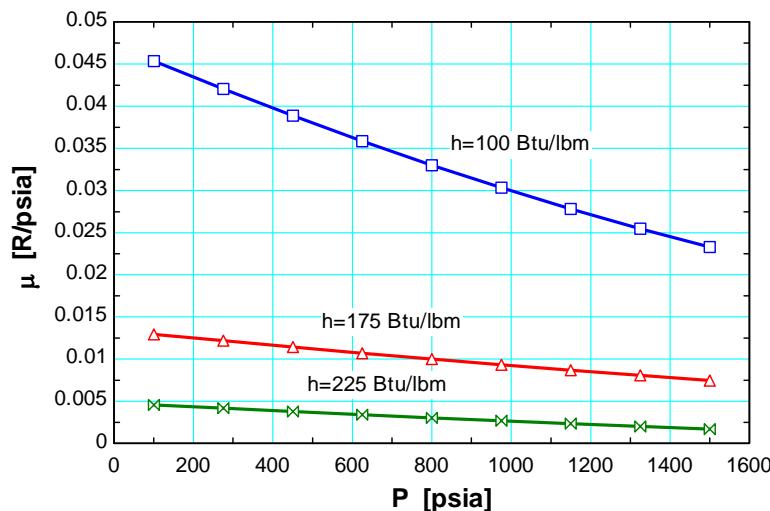

```

Gas$ = 'Nitrogen'
{P_ref=120 [psia]
T_ref=350 [R]
P= P_ref}
h=100 [Btu/lbm]
{h=enthalpy(Gas$, T=T_ref, P=P_ref)}
dP = 10 [psia]
T = temperature(Gas$, P=P, h=h)
P[1] = P + dP
P[2] = P - dP
T[1] = temperature(Gas$, P=P[1], h=h)
T[2] = temperature(Gas$, P=P[2], h=h)
Mu = DELTAT/DELTAP "Approximate the differential by differences about the state at h=const."
DELTAT=T[2]-T[1]
DELTAP=P[2]-P[1]

```

h = 225 Btu/lbm

P [psia]	μ [R/psia]
100	0.004573
275	0.00417
450	0.003781
625	0.003405
800	0.003041
975	0.002688
1150	0.002347
1325	0.002015
1500	0.001694

12-62 Steam is throttled slightly from 1 MPa and 300°C. It is to be determined if the temperature of the steam will increase, decrease, or remain the same during this process.

Analysis The enthalpy of steam at 1 MPa and $T = 300^\circ\text{C}$ is $h = 3051.6 \text{ kJ/kg}$. Now consider a throttling process from this state to 0.8 MPa, which is the next lowest pressure listed in the tables. The temperature of the steam at the end of this throttling process will be

$$\left. \begin{array}{l} P = 0.8 \text{ MPa} \\ h = 3051.6 \text{ kJ/kg} \end{array} \right\} T_2 = 297.52^\circ\text{C}$$

Therefore, the temperature will **decrease**.

12-63E The Joule-Thomson coefficient of refrigerant-134a at a given state is to be estimated.

Analysis The Joule-Thomson coefficient is defined as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h$$

We use a finite difference approximation as

$$\mu \approx \frac{T_2 - T_1}{P_2 - P_1} \quad (\text{at constant enthalpy})$$

At the given state (we call it state 1), the enthalpy of R-134a is

$$\left. \begin{array}{l} P_1 = 40 \text{ psia} \\ T_1 = 60^\circ\text{F} \end{array} \right\} h_1 = 113.79 \text{ Btu/lbm} \quad (\text{Table A - 13E})$$

The second state will be selected for a pressure of 30 psia. At this pressure and the same enthalpy, we have

$$\left. \begin{array}{l} P_2 = 30 \text{ psia} \\ h_2 = h_1 = 113.79 \text{ kJ/kg} \end{array} \right\} T_2 = 56.78^\circ\text{F} \quad (\text{Table A - 13E})$$

Substituting,

$$\mu \approx \frac{T_2 - T_1}{P_2 - P_1} = \frac{(56.78 - 60)\text{R}}{(30 - 40)\text{psia}} = \mathbf{0.322 \text{ R/psia}}$$

12-64 The Joule-Thomson coefficient of refrigerant-134a at a given state is to be estimated.

Analysis The Joule-Thomson coefficient is defined as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h$$

We use a finite difference approximation as

$$\mu \approx \frac{T_2 - T_1}{P_2 - P_1} \quad (\text{at constant enthalpy})$$

At the given state (we call it state 1), the enthalpy of R-134a is

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ T_1 = 90^\circ\text{C} \end{array} \right\} h_1 = 333.93 \text{ kJ/kg} \quad (\text{Table A - 13})$$

The second state will be selected for a pressure of 180 kPa. At this pressure and the same enthalpy, we have

$$\left. \begin{array}{l} P_2 = 180 \text{ kPa} \\ h_2 = h_1 = 333.93 \text{ kJ/kg} \end{array} \right\} T_2 = 89.78^\circ\text{C} \quad (\text{Table A - 13})$$

Substituting,

$$\mu \approx \frac{T_2 - T_1}{P_2 - P_1} = \frac{(89.78 - 90)\text{K}}{(180 - 200)\text{kPa}} = \mathbf{0.0110 \text{ K/kPa}}$$

12-65 The equation of state of a gas is given by $\nu = \frac{RT}{P} - \frac{bP}{T^2}$. An equation for the Joule-Thomson coefficient inversion line using this equation is to be derived.

Analysis From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[T \left(\frac{\partial \nu}{\partial T} \right)_P - \nu \right]$$

When $\mu = 0$ as it does on the inversion line, this equation becomes

$$T \left(\frac{\partial \nu}{\partial T} \right)_P = \nu$$

Using the equation of state to evaluate the partial derivative,

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P} + 2 \frac{bP}{T^3}$$

Substituting this result into the previous expression produces

$$\frac{RT}{P} + 2 \frac{bP}{T^2} = \frac{RT}{P} - \frac{bP}{T^2} \longrightarrow 3 \frac{bP}{T^2} = 0$$

The condition along the inversion line is then

$$P = 0$$

12-66 It is to be demonstrated that the Joule-Thomson coefficient is given by $\mu = \frac{T^2}{c_p} \left(\frac{\partial(\nu/T)}{\partial T} \right)_P$.

Analysis From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[T \left(\frac{\partial \nu}{\partial T} \right)_P - \nu \right]$$

Expanding the partial derivative of ν/T produces

$$\left(\frac{\partial \nu/T}{\partial T} \right)_P = \frac{1}{T} \left(\frac{\partial \nu}{\partial T} \right)_P - \frac{\nu}{T^2}$$

When this is multiplied by T^2 , the right-hand side becomes the same as the bracketed quantity above. Then,

$$\mu = \frac{T^2}{c_p} \left(\frac{\partial(\nu/T)}{\partial T} \right)_P$$

12-67 The most general equation of state for which the Joule-Thomson coefficient is always zero is to be determined.

Analysis From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[T \left(\frac{\partial \nu}{\partial T} \right)_P - \nu \right]$$

When $\mu = 0$, this equation becomes

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \frac{\nu}{T}$$

This can only be satisfied by an equation of state of the form

$$\frac{\nu}{T} = f(P)$$

where $f(P)$ is an arbitrary function of the pressure.

The dh , du , and ds of Real Gases

12-68C It is the variation of enthalpy with pressure at a fixed temperature.

12-69C As P_R approaches zero, the gas approaches ideal gas behavior. As a result, the deviation from ideal gas behavior diminishes.

12-70C So that a single chart can be used for all gases instead of a single particular gas.

12-71 The errors involved in the enthalpy and internal energy of CO₂ at 350 K and 10 MPa if it is assumed to be an ideal gas are to be determined.

Analysis (a) The enthalpy departure of CO₂ at the specified state is determined from the generalized chart to be (Fig. A-29)

$$\left. \begin{array}{l} T_R = \frac{T}{T_{cr}} = \frac{350}{304.2} = 1.151 \\ P_R = \frac{P}{P_{cr}} = \frac{10}{7.39} = 1.353 \end{array} \right\} \longrightarrow Z_h = \frac{(\bar{h}_{ideal} - \bar{h})_{T,P}}{R_u T_{cr}} = 1.5$$

CO₂
 350 K
 10 MPa

Thus,

$$\bar{h} = \bar{h}_{ideal} - Z_h R_u T_{cr} = 11,351 - [(1.5)(8.314)(304.2)] = 7,557 \text{ kJ/kmol}$$

and,

$$\text{Error} = \frac{(\bar{h}_{ideal} - \bar{h})_{T,P}}{\bar{h}} = \frac{11,351 - 7,557}{7,557} = 50.2\%$$

(b) At the calculated T_R and P_R the compressibility factor is determined from the compressibility chart to be Z = 0.65. Then using the definition of enthalpy, the internal energy is determined to be

$$\bar{u} = \bar{h} - P\bar{v} = \bar{h} - ZR_u T = 7557 - [(0.65)(8.314)(350)] = 5,666 \text{ kJ/kmol}$$

and,

$$\text{Error} = \frac{\bar{u}_{ideal} - \bar{u}}{\bar{u}} = \frac{8,439 - 5,666}{5,666} = 48.9\%$$

12-72 The enthalpy and entropy changes of nitrogen during a process are to be determined assuming ideal gas behavior and using generalized charts.

Analysis (a) Using data from the ideal gas property table of nitrogen (Table A-18),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 9306 - 6,537 = \mathbf{2769 \text{ kJ/kmol}}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 193.562 - 183.289 - 8.314 \times \ln \frac{12}{6} = \mathbf{4.510 \text{ kJ/kmol}\cdot K}$$

(b) The enthalpy and entropy departures of nitrogen at the specified states are determined from the generalized charts to be (Figs. A-29, A-30)

$$\left. \begin{array}{l} T_{R1} = \frac{T_1}{T_{cr}} = \frac{225}{126.2} = 1.783 \\ P_{R1} = \frac{P_1}{P_{cr}} = \frac{6}{3.39} = 1.770 \end{array} \right\} \longrightarrow Z_{h1} = 0.6 \text{ and } Z_{s1} = 0.25$$

and

$$\left. \begin{array}{l} T_{R2} = \frac{T_2}{T_{cr}} = \frac{320}{126.2} = 2.536 \\ P_{R2} = \frac{P_2}{P_{cr}} = \frac{12}{3.39} = 2.540 \end{array} \right\} \longrightarrow Z_{h2} = 0.4 \text{ and } Z_{s2} = 0.15$$

Substituting,

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= R_u T_{cr} (Z_{h1} - Z_{h2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314)(126.2)(0.6 - 0.4) + 2769 \\ &= \mathbf{2979 \text{ kJ/kmol}} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= R_u (Z_{s1} - Z_{s2}) + (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} \\ &= (8.314)(0.25 - 0.15) + 4.510 \\ &= \mathbf{5.341 \text{ kJ/kmol}\cdot K} \end{aligned}$$

12-73E The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

Properties The properties of water are (Table A-1E)

$$M = 18.015 \text{ lbm/lbmol}, T_{\text{cr}} = 1164.8 \text{ R}, P_{\text{cr}} = 3200 \text{ psia}$$

Analysis (a) The pressure of water vapor during this process is

$$P_1 = P_2 = P_{\text{sat} @ 500^\circ\text{F}} = 680.56 \text{ psia}$$

Using data from the ideal gas property table of water vapor (Table A-23),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 12,178.8 - 7738.0 = 4440.8 \text{ Btu/lbmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 53.556 - 49.843 - 0 = 3.713 \text{ Btu/lbmol} \cdot \text{R}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{960}{1164.8} = 0.824 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{680.56}{3200} = 0.213 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.340 \text{ and } Z_{s1} = 0.277$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{1460}{1164.8} = 1.253 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{680.56}{3200} = 0.213 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.157 \text{ and } Z_{s2} = 0.0903$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= 4440.8 - (1.9858)(1164.8)(0.157 - 0.340) = 4864 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= 3.713 - (1.9858)(0.0903 - 0.277) = 4.084 \text{ Btu/lbmol} \cdot \text{R} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{4864 \text{ Btu/lbmol}}{18.015 \text{ lbm/lbmol}} = \mathbf{270.0 \text{ Btu/lbm}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{4.084 \text{ Btu/lbmol} \cdot \text{R}}{18.015 \text{ lbm/lbmol}} = \mathbf{0.2267 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(b) The inlet and exit state properties of water are

$$\left. \begin{aligned} T_1 &= 500^\circ\text{F} \\ x_1 &= 1 \end{aligned} \right\} \begin{aligned} h_1 &= 1202.3 \text{ Btu/lbm} \\ s_1 &= 1.4334 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \quad (\text{Table A-4E})$$

$$\left. \begin{aligned} P_2 &= 680.56 \text{ psia} \\ T_2 &= 1000^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_2 &= 1515.7 \text{ Btu/lbm} \\ s_2 &= 1.7008 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \quad (\text{from EES})$$

The enthalpy and entropy changes are

$$h_2 - h_1 = 1515.7 - 1202.3 = \mathbf{313.4 \text{ Btu/lbm}}$$

$$s_2 - s_1 = 1.7008 - 1.4334 = \mathbf{0.2674 \text{ Btu/lbm} \cdot \text{R}}$$

12-74E The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

Properties The properties of water are (Table A-1E)

$$M = 18.015 \text{ lbm/lbmol}, T_{\text{cr}} = 1164.8 \text{ R}, P_{\text{cr}} = 3200 \text{ psia}$$

Analysis (a) Using data from the ideal gas property table of water vapor (Table A-23E),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 12,178.8 - 17,032.5 = -4853.7 \text{ Btu/lbmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 53.556 - 56.411 - 1.9858 \times \ln \frac{1000}{3000} = -0.6734 \text{ Btu/lbmol}\cdot\text{R}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{1960}{1164.8} = 1.683 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{3000}{3200} = 0.9375 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.387 \text{ and } Z_{s1} = 0.188$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{1460}{1164.8} = 1.253 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{1000}{3200} = 0.3125 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.233 \text{ and } Z_{s2} = 0.134$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= -4853.7 - (1.9858)(1164.8)(0.233 - 0.387) = -4497.5 \text{ Btu/lbmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= -0.6734 - (1.9858)(0.134 - 0.188) = -0.5662 \text{ Btu/lbmol}\cdot\text{R} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{-4497.5 \text{ Btu/lbmol}}{18.015 \text{ lbm/lbmol}} = \mathbf{-249.7 \text{ Btu/lbm}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{-0.5662 \text{ Btu/lbmol}\cdot\text{R}}{18.015 \text{ lbm/lbmol}} = \mathbf{-0.0314 \text{ Btu/lbm}\cdot\text{R}} \end{aligned}$$

(b) Using water tables (Table A-6E)

$$\left. \begin{aligned} P_1 &= 3000 \text{ psia} \\ T_1 &= 1500^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_1 &= 1764.6 \text{ Btu/lbm} \\ s_1 &= 1.6883 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

$$\left. \begin{aligned} P_2 &= 1000 \text{ psia} \\ T_2 &= 1000^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_2 &= 1506.2 \text{ Btu/lbm} \\ s_2 &= 1.6535 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

The enthalpy and entropy changes are

$$h_2 - h_1 = 1506.2 - 1764.6 = \mathbf{-258.4 \text{ Btu/lbm}}$$

$$s_2 - s_1 = 1.6535 - 1.6883 = \mathbf{-0.0348 \text{ Btu/lbm}\cdot\text{R}}$$

12-75 The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

Properties The properties of water are (Table A-1)

$$M = 18.015 \text{ kg/kmol}, T_{\text{cr}} = 647.1 \text{ K}, P_{\text{cr}} = 22.06 \text{ MPa}$$

Analysis Using data from the ideal gas property table of water vapor (Table A-23),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 23,082 - 30,754 = -7672 \text{ kJ/kmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 217.141 - 227.109 - 8.314 \times \ln \frac{500}{1000} = -4.2052 \text{ kJ/kmol}\cdot\text{K}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{873}{647.1} = 1.349 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{22.06} = 0.0453 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.0288 \text{ and } Z_{s1} = 0.0157$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{673}{647.1} = 1.040 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{0.5}{22.06} = 0.0227 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.0223 \text{ and } Z_{s2} = 0.0146$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= -7672 - (8.314)(647.1)(0.0223 - 0.0288) = -7637 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= -4.2052 - (8.314)(0.0146 - 0.0157) = -4.1961 \text{ kJ/kmol}\cdot\text{K} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{-7637 \text{ kJ/kmol}}{18.015 \text{ kg/kmol}} = \mathbf{-423.9 \text{ kJ/kg}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{-4.1961 \text{ kJ/kmol}\cdot\text{K}}{18.015 \text{ kg/kmol}} = \mathbf{-0.2329 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

The inlet and exit state properties of water vapor from Table A-6 are

$$\left. \begin{aligned} P_1 &= 1000 \text{ kPa} \\ T_1 &= 600^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &= 3698.6 \text{ kJ/kg} \\ s_1 &= 8.0311 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} P_2 &= 500 \text{ kPa} \\ T_2 &= 400^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_2 &= 3272.4 \text{ kJ/kg} \\ s_2 &= 7.7956 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

The enthalpy and entropy changes are

$$h_2 - h_1 = 3272.4 - 3698.6 = \mathbf{-426.2 \text{ kJ/kg}}$$

$$s_2 - s_1 = 7.7956 - 8.0311 = \mathbf{-0.2355 \text{ kJ/kg}\cdot\text{K}}$$

12-76 Methane is compressed adiabatically by a steady-flow compressor. The required power input to the compressor is to be determined using the generalized charts.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The steady-flow energy balance equation for this compressor can be expressed as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0$$

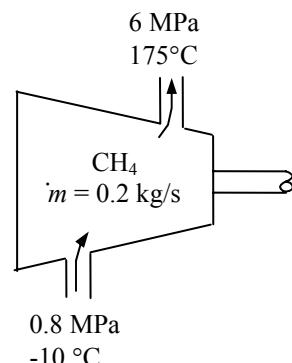

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{W}_{C,\text{in}} + \dot{m}h_1 = \dot{m}h_2$$

$$\dot{W}_{C,\text{in}} = \dot{m}(h_2 - h_1)$$

The enthalpy departures of CH₄ at the specified states are determined from the generalized charts to be (Fig. A-29)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{263}{191.1} = 1.376 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{0.8}{4.64} = 0.172 \end{aligned} \right\} \rightarrow Z_{h1} = 0.075$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{448}{191.1} = 2.34 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{6}{4.64} = 1.29 \end{aligned} \right\} \rightarrow Z_{h2} = 0.25$$

Thus,

$$\begin{aligned} h_2 - h_1 &= RT_{\text{cr}}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} \\ &= (0.5182)(191.1)(0.075 - 0.25) + 2.2537(175 - (-10)) \\ &= 399.6 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$\dot{W}_{C,\text{in}} = (0.2 \text{ kg/s})(399.6 \text{ kJ/kg}) = 79.9 \text{ kW}$$

12-77 Propane is to be adiabatically and reversibly compressed in a steady-flow device. The specific work required for this compression is to be determined using the departure charts and treating the propane as an ideal gas with temperature variable specific heats.

Properties The properties of propane are (Table A-1)

$$M = 44.097 \text{ kg/kmol}, R = 0.1885 \text{ kJ/kg} \cdot \text{K}, T_{\text{cr}} = 370 \text{ K}, P_{\text{cr}} = 4.26 \text{ MPa}$$

Analysis The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. When the entropy change equation is integrated with variable specific heats, it becomes

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1}$$

When the expression of Table A-2c is substituted for c_p and the integration performed, we obtain

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left(\frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \\ 0 &= -4.04 \ln \frac{T_2}{450} + 30.48 \left(\frac{T_2}{100} - 4.50 \right) - 0.786 \left[\left(\frac{T_2}{100} \right)^2 - 4.50^2 \right] + 0.01058 \left[\left(\frac{T_2}{100} \right)^3 - 4.50^3 \right] \\ &\quad - (8.314) \ln \frac{7000}{750} \end{aligned}$$

Solving this equation by EES or an iterative solution by hand gives

$$T_2 = 532 \text{ K}$$

When an energy balance is applied to the compressor, it becomes

$$\begin{aligned} \bar{w}_{\text{in}} &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \int_1^2 c_p dT = \int_1^2 (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= -4.04(532 - 450) + 0.1524(532^2 - 450^2) - 52.4(5.32^3 - 4.50^3) + 0.7935(5.32^4 - 4.50^4) \\ &= 9111 \text{ kJ/kmol} \end{aligned}$$

The work input per unit mass basis is

$$w_{\text{in}} = \frac{\bar{w}_{\text{in}}}{M} = \frac{9111 \text{ kJ/kmol}}{44.097 \text{ kg/kmol}} = 207 \text{ kJ/kg}$$

The enthalpy departures of propane at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

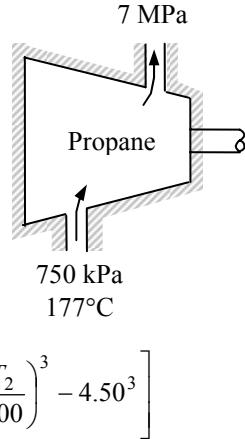

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{450}{370} = 1.22 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{0.5}{4.26} = 0.176 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.136$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{532}{370} = 1.44 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{7}{4.26} = 1.64 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.971$$

The work input (i.e., enthalpy change) is determined to be

$$\begin{aligned} w_{\text{in}} &= h_2 - h_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= 207 - (0.1885)(370)(0.971 - 0.136) \\ &= 148 \text{ kJ/kg} \end{aligned}$$

12-78E Oxygen is to be adiabatically and reversibly expanded in a nozzle. The exit velocity is to be determined using the departure charts and treating the oxygen as an ideal gas with temperature variable specific heats.

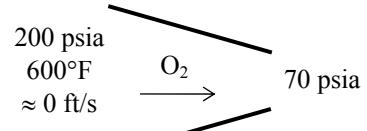

Properties The properties of oxygen are (Table A-1)

$$M = 31.999 \text{ lbm/lbmol}, R = 0.06206 \text{ Btu/lbm}\cdot\text{R}, T_{\text{cr}} = 278.6 \text{ R}, P_{\text{cr}} = 736 \text{ psia}$$

Analysis The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. From the entropy change equation for an ideal gas with variable specific heats:

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = 0$$

$$s_2^\circ - s_1^\circ = R_u \ln \frac{P_2}{P_1} = (1.9858) \ln \frac{70}{200} = -2.085 \text{ Btu/lbmol}\cdot\text{R}$$

Then from Table A-19E,

$$T_1 = 1060 \text{ R} \longrightarrow \bar{h}_{1,\text{ideal}} = 7543.6 \text{ Btu/lbmol}, s_1^\circ = 53.921 \text{ Btu/lbmol}\cdot\text{R}$$

$$s_2^\circ = s_1^\circ - 2.085 = 53.921 - 2.085 = 51.836 \text{ Btu/lbmol}\cdot\text{R}$$

$$s_2^\circ = 51.836 \text{ Btu/lbmol}\cdot\text{R} \longrightarrow T_2 = 802 \text{ R}, \bar{h}_{2,\text{ideal}} = 5614.1 \text{ Btu/lbmol}$$

The enthalpy change per mole basis is

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 5614.1 - 7543.6 = -1929.5 \text{ Btu/lbmol}$$

The enthalpy change per mass basis is

$$(h_2 - h_1)_{\text{ideal}} = \frac{(\bar{h}_2 - \bar{h}_1)_{\text{ideal}}}{M} = \frac{-1929.5 \text{ Btu/lbmol}}{31.999 \text{ lbm/lbmol}} = -60.30 \text{ Btu/lbm}$$

An energy balance on the nozzle gives

$$\begin{aligned} \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{m}(h_1 + V_1^2/2) &= \dot{m}(h_2 + V_2^2/2) \\ h_1 + V_1^2/2 &= h_2 + V_2^2/2 \end{aligned}$$

Solving for the exit velocity,

$$V_2 = [V_1^2 + 2(h_1 - h_2)]^{0.5} = \left[(0 \text{ ft/s})^2 + 2(60.30 \text{ Btu/lbm}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \right]^{0.5} = \mathbf{1738 \text{ ft/s}}$$

The enthalpy departures of oxygen at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{1060}{278.6} = 3.805 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{200}{736} = 0.272 \end{aligned} \right\} Z_{h1} = 0.000759 \quad \left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{802}{278.6} = 2.879 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{70}{736} = 0.0951 \end{aligned} \right\} Z_{h2} = 0.00894$$

The enthalpy change is

$$\begin{aligned} h_2 - h_1 &= (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= -60.30 \text{ Btu/lbm} - (0.06206 \text{ Btu/lbm}\cdot\text{R})(278.6 \text{ R})(0.00894 - 0.000759) \\ &= -60.44 \text{ Btu/lbm} \end{aligned}$$

The exit velocity is

$$V_2 = [V_1^2 + 2(h_1 - h_2)]^{0.5} = \left[(0 \text{ ft/s})^2 + 2(60.44 \text{ Btu/lbm}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \right]^{0.5} = \mathbf{1740 \text{ ft/s}}$$

12-79 Propane is compressed isothermally by a piston-cylinder device. The work done and the heat transfer are to be determined using the generalized charts.

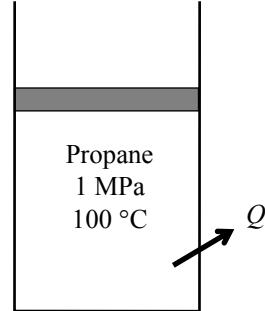

Assumptions 1 The compression process is quasi-equilibrium. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The enthalpy departure and the compressibility factors of propane at the initial and the final states are determined from the generalized charts to be (Figs. A-29, A-15)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{1}{4.26} = 0.235 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.28 \text{ and } Z_1 = 0.92$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \longrightarrow Z_{h2} = 1.8 \text{ and } Z_2 = 0.50$$

Treating propane as a real gas with $Z_{avg} = (Z_1 + Z_2)/2 = (0.92 + 0.50)/2 = 0.71$,

$$Pv = ZRT \approx Z_{avg} RT = C = \text{constant}$$

Then the boundary work becomes

$$\begin{aligned} w_{b,in} &= - \int_1^2 P d\nu = - \int_1^2 \frac{C}{\nu} d\nu = -C \ln \frac{\nu_2}{\nu_1} = Z_{avg} RT \ln \frac{Z_2 RT / P_2}{Z_1 RT / P_1} = -Z_{avg} RT \ln \frac{Z_2 P_1}{Z_1 P_2} \\ &= -(0.71)(0.1885 \text{ kJ/kg}\cdot\text{K})(373 \text{ K}) \ln \frac{(0.50)(1)}{(0.92)(4)} = 99.6 \text{ kJ/kg} \end{aligned}$$

Also,

$$h_2 - h_1 = RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{ideal} = (0.1885)(370)(0.28 - 1.8) + 0 = -106 \text{ kJ/kg}$$

$$u_2 - u_1 = (h_2 - h_1) - R(Z_2 T_2 - Z_1 T_1) = -106 - (0.1885)[(0.5)(373) - (0.92)(373)] = -76.5 \text{ kJ/kg}$$

Then the heat transfer for this process is determined from the closed system energy balance to be

$$E_{in} - E_{out} = \Delta E_{system}$$

$$q_{in} + w_{b,in} = \Delta u = u_2 - u_1$$

$$q_{in} = (u_2 - u_1) - w_{b,in} = -76.5 - 99.6 = -176.1 \text{ kJ/kg} \rightarrow q_{out} = 176.1 \text{ kJ/kg}$$

12-80 Problem 12-79 is reconsidered. This problem is to be extended to compare the solutions based on the ideal gas assumption, generalized chart data and real fluid (EES) data. Also, the solution is to be extended to carbon dioxide, nitrogen and methane.

Analysis The problem is solved using EES, and the solution is given below.

```

12-81 Propane is compressed isothermally by a piston-cylinder device. The exergy destruction associated with this process is to be determined.

Assumptions 1 The compression process is quasi-equilibrium. **2** Kinetic and potential energy changes are negligible.

Properties The gas constant of propane is $R = 0.1885 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis The exergy destruction is determined from its definition $x_{\text{destroyed}} = T_0 s_{\text{gen}}$ where the entropy generation is determined from an entropy balance on the contents of the cylinder. It gives

$$\begin{aligned} S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} &= \Delta S_{\text{system}} \\ -\frac{Q_{\text{out}}}{T_{b,\text{surr}}} + S_{\text{gen}} &= m(s_2 - s_1) \rightarrow s_{\text{gen}} = (s_2 - s_1) + \frac{q_{\text{out}}}{T_{\text{surr}}} \end{aligned}$$

where

$$\begin{aligned} \Delta s_{\text{sys}} &= s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} \\ (s_2 - s_1)_{\text{ideal}} &= c_p \ln \frac{T_2}{T_1}^{\gamma_0} - R \ln \frac{P_2}{P_1} = 0 - 0.1885 \ln \frac{4}{1} = -0.261 \text{ kJ/kg}\cdot\text{K} \\ \left. \begin{array}{l} T_{R1} = \frac{T_1}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R1} = \frac{P_1}{P_{\text{cr}}} = \frac{1}{4.26} = 0.235 \end{array} \right\} &\longrightarrow Z_{s1} = 0.21 \end{aligned}$$

and

$$\left. \begin{array}{l} T_{R2} = \frac{T_2}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R2} = \frac{P_2}{P_{\text{cr}}} = \frac{4}{4.26} = 0.939 \end{array} \right\} \longrightarrow Z_{s2} = 1.5$$

Thus,

$$\Delta s_{\text{sys}} = s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} = (0.1885)(0.21 - 1.5) - 0.261 = -0.504 \text{ kJ/kg}\cdot\text{K}$$

and

$$\begin{aligned} x_{\text{destroyed}} &= T_0 s_{\text{gen}} = T_0 \left((s_2 - s_1) + \frac{q_{\text{out}}}{T_{\text{surr}}} \right) \\ &= (303 \text{ K}) \left(-0.504 + \frac{176.1 \text{ kJ/kg}}{303 \text{ K}} \right) \text{ kJ/kg}\cdot\text{K} \\ &= \mathbf{23.4 \text{ kJ/kg}} \end{aligned}$$

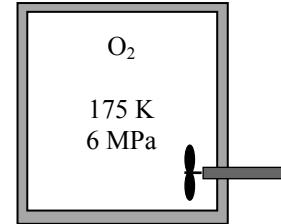

12-82 A paddle-wheel placed in a well-insulated rigid tank containing oxygen is turned on. The final pressure in the tank and the paddle-wheel work done during this process are to be determined.

Assumptions 1The tank is well-insulated and thus heat transfer is negligible. 2 Kinetic and potential energy changes are negligible.

Properties The gas constant of O₂ is $R = 0.2598 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) For this problem, we use critical properties, compressibility factor, and enthalpy departure factors in EES. The compressibility factor of oxygen at the initial state is determined from EES to be

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{175}{154.6} = 1.13 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{6}{5.043} = 1.19 \end{aligned} \right\} \longrightarrow Z_1 = 0.682 \text{ and } Z_{h1} = 1.33$$

Then,

$$Pv = ZRT \longrightarrow v_1 = \frac{(0.682)(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(175 \text{ K})}{6000 \text{ kPa}} = 0.00516 \text{ m}^3/\text{kg}$$

$$m = \frac{v}{v_1} = \frac{0.05 \text{ m}^3}{0.00516 \text{ m}^3/\text{kg}} = 9.68 \text{ kg}$$

The specific volume of oxygen remains constant during this process, $v_2 = v_1$. Thus,

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{225}{154.8} = 1.46 \\ v_{R2} &= \frac{v_2}{RT_{cr}/P_{cr}} = \frac{0.00516 \text{ m}^3/\text{kg}}{(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(154.6 \text{ K})/(5043 \text{ kPa})} = 0.649 \end{aligned} \right\} \begin{aligned} Z_2 &= 0.853 \\ Z_{h2} &= 1.09 \\ P_{R2} &= 1.91 \end{aligned}$$

$$P_2 = P_{R2}P_{cr} = (1.91)(5043) = 9652 \text{ kPa}$$

(b) The energy balance relation for this closed system can be expressed as

$$\begin{aligned} E_{in} - E_{out} &= \Delta E_{system} \\ W_{in} &= \Delta U = m(u_2 - u_1) \\ W_{in} &= m[h_2 - h_1 - (P_2v_2 - P_1v_1)] = m[h_2 - h_1 - R(Z_2T_2 - Z_1T_1)] \end{aligned}$$

where

$$\begin{aligned} h_2 - h_1 &= RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{ideal} \\ &= (0.2598)(154.6)(1.33 - 1.09) + 52.96 \\ &= 62.51 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$W_{in} = (9.68 \text{ kg})[62.51 - (0.2598 \text{ kJ/kg}\cdot\text{K})\{(0.853)(225) - (0.682)(175)\}] = 423 \text{ kJ}$$

Discussion The following routine in EES is used to get the solution above. Reading values from Fig. A-15 and A-29 together with properties in the book could yield different results.

12-83 The heat transfer and entropy changes of CO₂ during a process are to be determined assuming ideal gas behavior, using generalized charts, and real fluid (EES) data.

Analysis The temperature at the final state is

$$T_2 = T_1 \frac{P_2}{P_1} = (100 + 273 \text{ K}) \frac{8 \text{ MPa}}{1 \text{ MPa}} = 2984 \text{ K}$$

Using data from the ideal gas property table of CO₂ (Table A-20),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 161,293 - 12,269 = 149,024 \text{ kJ/kmol}$$

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 333.770 - 222.367 - 8.314 \times \ln \frac{8}{1} = 94.115 \text{ kJ/kmol}\cdot\text{K}$$

$$(h_2 - h_1)_{\text{ideal}} = \frac{(\bar{h}_2 - \bar{h}_1)_{\text{ideal}}}{M} = \frac{149,024 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = 3386.9 \text{ kJ/kg}$$

The heat transfer is determined from an energy balance noting that there is no work interaction

$$\begin{aligned} q_{\text{ideal}} &= (u_2 - u_1)_{\text{ideal}} = (h_2 - h_1)_{\text{ideal}} - R(T_2 - T_1) \\ &= 3386.9 \text{ kJ/kg} - (0.1889 \text{ kJ/kg.K})(2984 - 373) = \mathbf{2893.7 \text{ kJ/kg}} \end{aligned}$$

The entropy change is

$$\Delta s_{\text{ideal}} = (s_2 - s_1)_{\text{ideal}} = \frac{(\bar{s}_2 - \bar{s}_1)_{\text{ideal}}}{M} = \frac{94.115 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = \mathbf{2.1390 \text{ kJ/kg.K}}$$

The compressibility factor and the enthalpy and entropy departures of CO₂ at the specified states are determined from the generalized charts to be (we used EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{304.2} = 1.226 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{7.39} = 0.135 \end{aligned} \right\} \longrightarrow Z_1 = 0.976, Z_{h1} = 0.1028 \text{ and } Z_{s1} = 0.05987$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{2985}{304.2} = 9.813 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{8}{7.39} = 1.083 \end{aligned} \right\} \longrightarrow Z_2 = 1.009, Z_{h2} = -0.1144 \text{ and } Z_{s2} = -0.002685$$

Thus,

$$\begin{aligned} q_{\text{chart}} &= u_2 - u_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) - Z_1 R(T_2 - T_1) \\ &= 3386.9 - (0.1889)(304.2)(-0.1144 - 0.1028) - (0.976)(0.1889)(2887 - 373) = \mathbf{2935.9 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} \Delta s_{\text{chart}} &= (s_2 - s_1)_{\text{chart}} = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} \\ &= (0.1889)(0.05987 - (-0.002685)) + 2.1390 = \mathbf{2.151 \text{ kJ/kg.K}} \end{aligned}$$

Note that the temperature at the final state in this case was determined from

$$T_2 = T_1 \frac{P_2}{P_1} \frac{Z_1}{Z_2} = (100 + 273 \text{ K}) \frac{8 \text{ MPa}}{1 \text{ MPa}} \frac{0.976}{1.009} = 2888 \text{ K}$$

The solution using EES built-in property data is as follows:

$$\left. \begin{aligned} T_1 &= 373 \text{ K} \\ P_1 &= 1 \text{ MPa} \end{aligned} \right\} \begin{aligned} v_1 &= 0.06885 \text{ m}^3/\text{kg} \\ u_1 &= -8.614 \text{ kJ/kg} \\ s_1 &= -0.2464 \text{ kJ/kg.K} \end{aligned} \quad \left. \begin{aligned} P_2 &= 8 \text{ MPa} \\ v_2 &= v_1 = 0.06885 \text{ m}^3/\text{kg} \end{aligned} \right\} \begin{aligned} T_2 &= 2879 \text{ K} \\ u_2 &= 2754 \text{ kJ/kg} \\ s_2 &= 1.85 \text{ kJ/kg.K} \end{aligned}$$

Then

$$q_{\text{EES}} = u_2 - u_1 = 2754 - (-8.614) = \mathbf{2763 \text{ kJ/kg}}$$

$$\Delta s_{\text{EES}} = (s_2 - s_1)_{\text{EES}} = s_2 - s_1 = 1.85 - (-0.2464) = \mathbf{2.097 \text{ kJ/kg.K}}$$

Review Problems

12-84 It is to be shown that the slope of a constant-pressure line on an $h-s$ diagram is constant in the saturation region and increases with temperature in the superheated region.

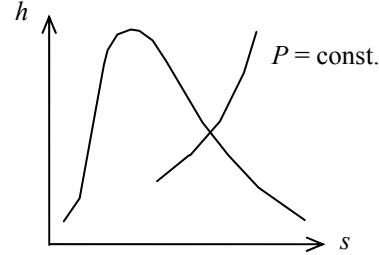

Analysis For $P = \text{constant}$, $dP = 0$ and the given relation reduces to $dh = Tds$, which can also be expressed as

$$\left(\frac{\partial h}{\partial s}\right)_P = T$$

Thus the slope of the $P = \text{constant}$ lines on an $h-s$ diagram is equal to the temperature.

(a) In the saturation region, $T = \text{constant}$ for $P = \text{constant}$ lines, and the slope remains constant.

(b) In the superheat region, the slope increases with increasing temperature since the slope is equal temperature.

12-85 Using the cyclic relation and the first Maxwell relation, the other three Maxwell relations are to be obtained.

Analysis (1) Using the properties P, s, v , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial s}\right)_v \left(\frac{\partial s}{\partial v}\right)_P \left(\frac{\partial v}{\partial P}\right)_s = -1$$

Substituting the first Maxwell relation, $\left(\frac{\partial T}{\partial v}\right)_s = -\left(\frac{\partial P}{\partial s}\right)_v$,

$$-\left(\frac{\partial T}{\partial v}\right)_s \left(\frac{\partial s}{\partial v}\right)_P \left(\frac{\partial v}{\partial P}\right)_s = -1 \longrightarrow \left(\frac{\partial T}{\partial P}\right)_s \left(\frac{\partial s}{\partial v}\right)_P = 1 \longrightarrow \left(\frac{\partial T}{\partial P}\right)_s = \left(\frac{\partial v}{\partial s}\right)_P$$

(2) Using the properties T, v, s , the cyclic relation can be expressed as

$$\left(\frac{\partial T}{\partial v}\right)_s \left(\frac{\partial v}{\partial s}\right)_T \left(\frac{\partial s}{\partial T}\right)_v = -1$$

Substituting the first Maxwell relation, $\left(\frac{\partial T}{\partial v}\right)_s = -\left(\frac{\partial P}{\partial s}\right)_v$,

$$-\left(\frac{\partial P}{\partial s}\right)_v \left(\frac{\partial v}{\partial s}\right)_T \left(\frac{\partial s}{\partial T}\right)_v = -1 \longrightarrow \left(\frac{\partial P}{\partial T}\right)_v \left(\frac{\partial v}{\partial s}\right)_T = 1 \longrightarrow \left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial P}{\partial T}\right)_v$$

(3) Using the properties P, T, v , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial T}\right)_v \left(\frac{\partial T}{\partial v}\right)_P \left(\frac{\partial v}{\partial P}\right)_T = -1$$

Substituting the third Maxwell relation, $\left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial P}{\partial T}\right)_v$,

$$\left(\frac{\partial s}{\partial v}\right)_T \left(\frac{\partial T}{\partial v}\right)_P \left(\frac{\partial v}{\partial P}\right)_T = -1 \longrightarrow \left(\frac{\partial s}{\partial P}\right)_T \left(\frac{\partial T}{\partial v}\right)_P = -1 \longrightarrow \left(\frac{\partial s}{\partial P}\right)_T = -\left(\frac{\partial v}{\partial T}\right)_P$$

12-86 For $\beta \geq 0$, it is to be shown that at every point of a single-phase region of an $h-s$ diagram, the slope of a constant-pressure line is greater than the slope of a constant-temperature line, but less than the slope of a constant-volume line.

Analysis It is given that $\beta > 0$.

Using the Tds relation: $dh = Tds + \nu dP \longrightarrow \frac{dh}{ds} = T + \nu \frac{dP}{ds}$

$$(1) P = \text{constant}: \quad \left(\frac{\partial h}{\partial s} \right)_P = T$$

$$(2) T = \text{constant}: \quad \left(\frac{\partial h}{\partial s} \right)_T = T + \nu \left(\frac{\partial P}{\partial s} \right)_T$$

$$\text{But the 4th Maxwell relation: } \left(\frac{\partial P}{\partial s} \right)_T = - \left(\frac{\partial T}{\partial \nu} \right)_P$$

$$\text{Substituting: } \left(\frac{\partial h}{\partial s} \right)_T = T - \nu \left(\frac{\partial T}{\partial \nu} \right)_P = T - \frac{1}{\beta}$$

Therefore, the slope of $P = \text{constant}$ lines is **greater** than the slope of $T = \text{constant}$ lines.

$$(3) \nu = \text{constant}: \quad \left(\frac{\partial h}{\partial s} \right)_\nu = T + \nu \left(\frac{\partial P}{\partial s} \right)_\nu \quad (a)$$

$$\text{From the } ds \text{ relation: } ds = \frac{c_\nu}{T} dT + \left(\frac{\partial P}{\partial T} \right)_\nu d\nu$$

$$\text{Divide by } dP \text{ holding } \nu \text{ constant: } \left(\frac{\partial s}{\partial P} \right)_\nu = \frac{c_\nu}{T} \left(\frac{\partial T}{\partial P} \right)_\nu \quad \text{or} \quad \left(\frac{\partial P}{\partial s} \right)_\nu = \frac{T}{c_\nu} \left(\frac{\partial T}{\partial P} \right)_\nu \quad (b)$$

Using the properties P, T, ν , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial T} \right)_\nu \left(\frac{\partial T}{\partial \nu} \right)_P \left(\frac{\partial \nu}{\partial P} \right)_T = -1 \longrightarrow \left(\frac{\partial P}{\partial T} \right)_\nu = - \left(\frac{\partial \nu}{\partial T} \right)_P \left(\frac{\partial P}{\partial \nu} \right)_T = (-\beta \nu) \left(\frac{1}{-\alpha \nu} \right) = \frac{\beta}{\alpha} \quad (c)$$

where we used the definitions of α and β . Substituting (b) and (c) into (a),

$$\left(\frac{\partial h}{\partial s} \right)_\nu = T + \nu \left(\frac{\partial P}{\partial s} \right)_\nu = T + \frac{T\beta \nu}{c_\nu \alpha} > T$$

Here α is positive for all phases of all substances. T is the absolute temperature that is also positive, so is c_ν . Therefore, the second term on the right is always a positive quantity since β is given to be positive. Then we conclude that the slope of $P = \text{constant}$ lines is **less** than the slope of $\nu = \text{constant}$ lines.

12-87 It is to be shown that

$$c_v = -T \left(\frac{\partial v}{\partial T} \right)_s \quad \text{and} \quad c_p = T \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial v}{\partial T} \right)_P$$

Analysis Using the definition of c_v ,

$$c_v = T \left(\frac{\partial s}{\partial T} \right)_v = T \left(\frac{\partial s}{\partial P} \right)_v \left(\frac{\partial P}{\partial T} \right)_v$$

Substituting the first Maxwell relation $\left(\frac{\partial s}{\partial P} \right)_v = -\left(\frac{\partial v}{\partial T} \right)_s$,

$$c_v = -T \left(\frac{\partial v}{\partial T} \right)_s \left(\frac{\partial P}{\partial T} \right)_v$$

Using the definition of c_p ,

$$c_p = T \left(\frac{\partial s}{\partial T} \right)_P = T \left(\frac{\partial s}{\partial v} \right)_P \left(\frac{\partial v}{\partial T} \right)_P$$

Substituting the second Maxwell relation $\left(\frac{\partial s}{\partial v} \right)_P = \left(\frac{\partial P}{\partial T} \right)_s$,

$$c_p = T \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial v}{\partial T} \right)_P$$

12-88 It is to be proven that for a simple compressible substance $\left(\frac{\partial s}{\partial v} \right)_u = \frac{P}{T}$.

Analysis The proof is simply obtained as

$$\left(\frac{\partial s}{\partial v} \right)_u = \frac{-\left(\frac{\partial u}{\partial v} \right)_s}{\left(\frac{\partial u}{\partial s} \right)_v} = -\frac{-P}{T} = \frac{P}{T}$$

12-89 It is to be proven by using the definitions of pressure and temperature, $T = \left(\frac{\partial u}{\partial s}\right)_v$ and $P = -\left(\frac{\partial u}{\partial v}\right)_s$ that for ideal gases, the development of the constant-pressure specific heat yields $\left(\frac{\partial h}{\partial P}\right)_T = 0$

Analysis The definition for enthalpy is

$$h = u + Pv$$

Then,

$$\left(\frac{\partial h}{\partial P}\right)_T = \left(\frac{\partial u}{\partial P}\right)_T + P\left(\frac{\partial v}{\partial P}\right)_T + v\left(\frac{\partial P}{\partial P}\right)_T$$

Assume $u = u(s, v)$

Then,

$$du = \left(\frac{\partial u}{\partial s}\right)_v ds + \left(\frac{\partial u}{\partial v}\right)_s dv$$

$$\left(\frac{\partial u}{\partial P}\right)_T = \left(\frac{\partial u}{\partial s}\right)_v \left(\frac{\partial s}{\partial P}\right)_T + \left(\frac{\partial u}{\partial v}\right)_s \left(\frac{\partial v}{\partial P}\right)_T$$

$$\left(\frac{\partial u}{\partial P}\right)_T = T \left[-\left(\frac{\partial v}{\partial T}\right)_P \right] - P \left(\frac{\partial v}{\partial P}\right)_T = -(T + P) \left(\frac{\partial v}{\partial P}\right)_T$$

$$\left(\frac{\partial h}{\partial P}\right)_T = -(T + P) \left(\frac{\partial v}{\partial P}\right)_T + P \left(\frac{\partial v}{\partial P}\right)_T + v = -T \left(\frac{\partial v}{\partial P}\right)_T + v$$

For ideal gases

$$v = \frac{RT}{P} \quad \text{and} \quad \left(\frac{\partial v}{\partial P}\right)_T = \frac{R}{P}$$

Then,

$$\left(\frac{\partial h}{\partial P}\right)_T = -\frac{TR}{P} + v = -v + v = 0$$

12-90 It is to be proven by using the definitions of pressure and temperature, $T = \left(\frac{\partial u}{\partial s}\right)_v$ and $P = -\left(\frac{\partial u}{\partial v}\right)_s$ that for ideal gases, the development of the constant-volume specific heat yields $\left(\frac{\partial u}{\partial v}\right)_T = 0$.

Analysis Assume $u = u(s, v)$

Then,

$$\begin{aligned} du &= \left(\frac{\partial u}{\partial s}\right)_v ds + \left(\frac{\partial u}{\partial v}\right)_s dv \\ \left(\frac{\partial u}{\partial v}\right)_T &= \left(\frac{\partial u}{\partial s}\right)_v \left(\frac{\partial s}{\partial v}\right)_T + \left(\frac{\partial u}{\partial v}\right)_s \left(\frac{\partial v}{\partial v}\right)_T \\ &= T \left(\frac{\partial s}{\partial v}\right)_T + P \end{aligned}$$

From Maxwell equation,

$$T \left(\frac{\partial s}{\partial v}\right)_T + P = T \left(\frac{\partial P}{\partial T}\right)_v - P$$

For ideal gases

$$P = \frac{RT}{v} \quad \text{and} \quad \left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v}$$

Then,

$$\left(\frac{\partial u}{\partial v}\right)_T = T \frac{R}{v} - P = P - P = 0$$

12-91 Expressions for h , u , s^o , P_r , and ν_r for an ideal gas whose c_p^o is given by $c_p^o = \sum a_i \left[\ln\left(\frac{T}{T_r}\right) \right]^{i-n}$ are to be developed.

Analysis By making the change in variable, $x = \ln(T/T_r)$, the enthalpy of this substance relative to a reference state is given by

$$\begin{aligned} h &= \int_{T_{ref}}^T c_p dT = \sum a_i \int_{x_{ref}}^x x^{i-n} e^x dx \\ &= \sum a_i e^x \left[x^{i-n} - (i-n)x^{i-n-1} + (i-n)(i-n-1)x^{i-n-2} - \dots + (-1)^{i-n} (i-n)! \right] \\ &\quad - x_{ref}^{i-n} + (i-n)x_{ref}^{i-n-1} - (i-n)(i-n-1)x_{ref}^{i-n-2} + \dots - (-1)^{i-n} (i-n)! \end{aligned}$$

Similarly, s^o is given by

$$\begin{aligned} s^o &= \int_{T_{ref}}^T \left(\frac{c_p}{T} \right) dT = \sum a_i T_r \int_{x_{ref}}^x x^{i-n} e^{2x} dx \\ &= \sum \frac{a_i e^{2x}}{2^{i-n}} \left[(2x)^{i-n} - (i-n)(2x)^{i-n-1} + (i-n)(i-n-1)(2x)^{i-n-2} - \dots + (-1)^{i-n} (i-n)! \right. \\ &\quad \left. - (2x_{ref})^{i-n} + (i-n)(2x_{ref})^{i-n-1} - (i-n)(i-n-1)(2x_{ref})^{i-n-2} + \dots - (-1)^{i-n} (i-n)! \right] \end{aligned}$$

With these two results,

$$u = h - P\nu$$

$$P_r = e^{s^o/R}$$

According to the du form of Gibbs equations,

$$\frac{du}{T} = -R \frac{d\nu}{\nu}$$

Noting that for ideal gases, $c_\nu = c_p - R$ and $du = c_\nu dT$, this expression reduces to

$$(c_p - R) \frac{dT}{T} = -R \frac{d\nu}{\nu}$$

When this is integrated between the reference and actual states, the result is

$$\int c_p \frac{dT}{T} - R \ln \frac{T}{T_{ref}} = -R \ln \frac{\nu}{\nu_{ref}}$$

Solving this for the specific volume ratio gives

$$\frac{\nu}{\nu_{ref}} = \exp[-(s^o - R(T - T_{ref}))R]$$

The ratio of the specific volumes at two states which have the same entropy is then

$$\frac{\nu}{\nu_{ref}} = \exp[-(s_2^o - s_1^o - R(T_2 - T_1))R]$$

Inspection of this result gives

$$\nu_r = \exp[-(s^o - RT)/R]$$

12-92 It is to be shown that the position of the Joule-Thompson coefficient inversion curve on the T - P plane is given by $(\partial Z / \partial T)_P = 0$.

Analysis The inversion curve is the locus of the points at which the Joule-Thompson coefficient μ is zero,

$$\mu = \frac{1}{c_p} \left(T \left(\frac{\partial \nu}{\partial T} \right)_P - \nu \right) = 0$$

which can also be written as

$$T \left(\frac{\partial \nu}{\partial T} \right)_P - \frac{ZRT}{P} = 0 \quad (a)$$

since it is given that

$$\nu = \frac{ZRT}{P} \quad (b)$$

Taking the derivative of (b) with respect to T holding P constant gives

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \left(\frac{\partial (ZRT / P)}{\partial T} \right)_P = \frac{R}{P} \left(T \left(\frac{\partial Z}{\partial T} \right)_P + Z \right)$$

Substituting in (a),

$$\begin{aligned} \frac{TR}{P} \left(T \left(\frac{\partial Z}{\partial T} \right)_P + Z \right) - \frac{ZRT}{P} &= 0 \\ T \left(\frac{\partial Z}{\partial T} \right)_P + Z - Z &= 0 \\ \left(\frac{\partial Z}{\partial T} \right)_P &= 0 \end{aligned}$$

which is the desired relation.

12-93 It is to be shown that for an isentropic expansion or compression process $Pv^k = \text{constant}$. It is also to be shown that the isentropic expansion exponent k reduces to the specific heat ratio c_p/c_v for an ideal gas.

Analysis We note that $ds = 0$ for an isentropic process. Taking $s = s(P, v)$, the total differential ds can be expressed as

$$ds = \left(\frac{\partial s}{\partial P} \right)_v dP + \left(\frac{\partial s}{\partial v} \right)_P dv = 0 \quad (a)$$

We now substitute the Maxwell relations below into (a)

$$\left(\frac{\partial s}{\partial P} \right)_v = - \left(\frac{\partial v}{\partial T} \right)_s \quad \text{and} \quad \left(\frac{\partial s}{\partial v} \right)_P = \left(\frac{\partial P}{\partial T} \right)_s$$

to get

$$- \left(\frac{\partial v}{\partial T} \right)_s dP + \left(\frac{\partial P}{\partial T} \right)_s dv = 0$$

Rearranging,

$$dP - \left(\frac{\partial T}{\partial v} \right)_s \left(\frac{\partial P}{\partial T} \right)_s dv = 0 \longrightarrow dP - \left(\frac{\partial P}{\partial v} \right)_s dv = 0$$

$$\text{Dividing by } P, \quad \frac{dP}{P} - \frac{1}{P} \left(\frac{\partial P}{\partial v} \right)_s dv = 0 \quad (b)$$

We now define isentropic expansion exponent k as

$$k = - \frac{v}{P} \left(\frac{\partial P}{\partial v} \right)_s$$

Substituting in (b),

$$\frac{dP}{P} + k \frac{dv}{v} = 0$$

Taking k to be a constant and integrating,

$$\ln P + k \ln v = \text{constant} \longrightarrow \ln Pv^k = \text{constant}$$

Thus,

$$Pv^k = \text{constant}$$

To show that $k = c_p/c_v$ for an ideal gas, we write the cyclic relations for the following two groups of variables:

$$(s, T, v) \longrightarrow \left(\frac{\partial s}{\partial T} \right)_v \left(\frac{\partial v}{\partial s} \right)_T \left(\frac{\partial T}{\partial v} \right)_s = -1 \longrightarrow \frac{c_v}{T} \left(\frac{\partial v}{\partial s} \right)_T \left(\frac{\partial T}{\partial v} \right)_s = -1 \quad (c)$$

$$(s, T, P) \longrightarrow \left(\frac{\partial s}{\partial T} \right)_P \left(\frac{\partial P}{\partial s} \right)_T \left(\frac{\partial T}{\partial P} \right)_s = -1 \longrightarrow \frac{c_p}{T} \left(\frac{\partial P}{\partial s} \right)_T \left(\frac{\partial T}{\partial P} \right)_s = -1 \quad (d)$$

where we used the relations

$$c_v = T \left(\frac{\partial s}{\partial T} \right)_v \quad \text{and} \quad c_p = T \left(\frac{\partial s}{\partial T} \right)_P$$

Setting Eqs. (c) and (d) equal to each other,

$$\frac{c_p}{T} \left(\frac{\partial P}{\partial s} \right)_T \left(\frac{\partial T}{\partial P} \right)_s = \frac{c_v}{T} \left(\frac{\partial v}{\partial s} \right)_T \left(\frac{\partial T}{\partial v} \right)_s$$

or,

$$\frac{c_p}{c_v} = \left(\frac{\partial s}{\partial P} \right)_T \left(\frac{\partial P}{\partial s} \right)_s \left(\frac{\partial v}{\partial T} \right)_s \left(\frac{\partial T}{\partial v} \right)_s = \left(\frac{\partial s}{\partial P} \frac{\partial v}{\partial s} \right)_T \left(\frac{\partial P}{\partial T} \frac{\partial T}{\partial v} \right)_s = \left(\frac{\partial v}{\partial P} \right)_T \left(\frac{\partial P}{\partial v} \right)_s$$

but

$$\left(\frac{\partial v}{\partial P} \right)_T = \left(\frac{\partial (RT/P)}{\partial P} \right)_T = -\frac{v}{P}$$

Substituting,

$$\frac{c_p}{c_v} = -\frac{v}{P} \left(\frac{\partial P}{\partial v} \right)_s = k$$

which is the desired relation.

12-94 The c_p of nitrogen at 300 kPa and 400 K is to be estimated using the relation given and its definition, and the results are to be compared to the value listed in Table A-2b.

Analysis (a) We treat nitrogen as an ideal gas with $R = 0.297 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.397$. Note that $PT^{k/(k-1)} = C = \text{constant}$ for the isentropic processes of ideal gases. The c_p relation is given as

$$\begin{aligned} c_p &= T \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial v}{\partial T} \right)_P \\ v &= \frac{RT}{P} \longrightarrow \left(\frac{\partial v}{\partial T} \right)_P = \frac{R}{P} \\ P &= CT^{k/(k-1)} \longrightarrow \left(\frac{\partial P}{\partial T} \right)_s = \frac{k}{k-1} CT^{k/(k-1)-1} = \frac{k}{k-1} (PT^{-k/(k-1)}) T^{k/(k-1)-1} = \frac{kP}{T(k-1)} \end{aligned}$$

Substituting,

$$c_p = T \left(\frac{kP}{T(k-1)} \right) \left(\frac{R}{P} \right) = \frac{kR}{k-1} = \frac{1.397(0.297 \text{ kJ/kg}\cdot\text{K})}{1.397 - 1} = 1.045 \text{ kJ/kg}\cdot\text{K}$$

(b) The c_p is defined as $c_p = \left(\frac{\partial h}{\partial T} \right)_P$. Replacing the differentials by differences,

$$c_p \approx \left(\frac{\Delta h}{\Delta T} \right)_{P=300\text{kPa}} = \frac{h(410 \text{ K}) - h(390 \text{ K})}{(410 - 390) \text{ K}} = \frac{(11,932 - 11,347)/28.0 \text{ kJ/kg}}{(410 - 390) \text{ K}} = 1.045 \text{ kJ/kg}\cdot\text{K}$$

(Compare: Table A-2b at 400 K $\rightarrow c_p = 1.044 \text{ kJ/kg}\cdot\text{K}$)

12-95 The temperature change of steam and the average Joule-Thompson coefficient during a throttling process are to be estimated.

Analysis The enthalpy of steam at 4.5 MPa and $T = 300^\circ\text{C}$ is $h = 2944.2 \text{ kJ/kg}$. Now consider a throttling process from this state to 2.5 MPa. The temperature of the steam at the end of this throttling process will be

$$\left. \begin{array}{l} P = 2.5 \text{ MPa} \\ h = 2944.2 \text{ kJ/kg} \end{array} \right\} T_2 = 273.72^\circ\text{C}$$

Thus the temperature drop during this throttling process is

$$\Delta T = T_2 - T_1 = 273.72 - 300 = -26.28^\circ\text{C}$$

The average Joule-Thomson coefficient for this process is determined from

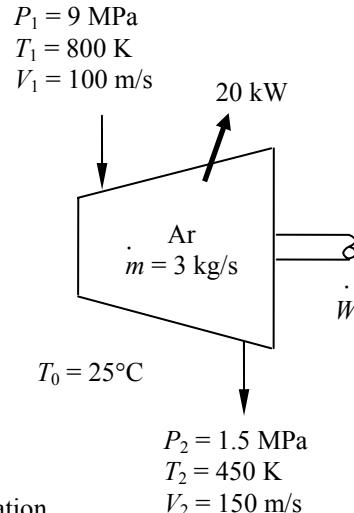

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \approx \left(\frac{\Delta T}{\Delta P} \right)_{h=3204.7\text{kJ/kg}} = \frac{(273.72 - 300)^\circ\text{C}}{(2.5 - 4.5)\text{MPa}} = 13.14^\circ\text{C/MPa}$$

12-96 Argon enters a turbine at a specified state and leaves at another specified state. Power output of the turbine and exergy destruction during this process are to be determined using the generalized charts.

Properties The gas constant and critical properties of Argon are $R = 0.2081 \text{ kJ/kg.K}$, $T_{\text{cr}} = 151 \text{ K}$, and $P_{\text{cr}} = 4.86 \text{ MPa}$ (Table A-1).

Analysis (a) The enthalpy and entropy departures of argon at the specified states are determined from the generalized charts to be

$$\left. \begin{aligned} T_{R_1} &= \frac{T_1}{T_{\text{cr}}} = \frac{800}{151} = 5.30 \\ P_{R_1} &= \frac{P_1}{P_{\text{cr}}} = \frac{9}{4.86} = 1.85 \end{aligned} \right\} Z_{h_1} \approx 0 \text{ and } Z_{s_1} \approx 0$$

Thus argon behaves as an ideal gas at turbine inlet. Also,

$$\left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{\text{cr}}} = \frac{450}{151} = 2.98 \\ P_{R_2} &= \frac{P_2}{P_{\text{cr}}} = \frac{1.5}{4.86} = 0.309 \end{aligned} \right\} Z_{h_2} = 0.024 \text{ and } Z_{s_2} = 0.013$$

Thus,

$$\begin{aligned} h_2 - h_1 &= RT_{\text{cr}}(Z_{h_1} - Z_{h_2}) + (h_2 - h_1)_{\text{ideal}} \\ &= (0.2081)(151)(0 - 0.024) + 0.5203(450 - 800) = -182.9 \text{ kJ/kg} \end{aligned}$$

The power output of the turbine is to be determined from the energy balance equation,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} = 0 \text{ (steady)} \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \dot{m}(h_1 + V_1^2/2) &= \dot{m}(h_2 + V_2^2/2) + \dot{Q}_{\text{out}} + \dot{W}_{\text{out}} \\ \dot{W}_{\text{out}} &= -\dot{m} \left[(h_2 - h_1) + \frac{V_2^2 - V_1^2}{2} \right] - \dot{Q}_{\text{out}} \end{aligned}$$

Substituting,

$$\dot{W}_{\text{out}} = -(3 \text{ kg/s}) \left(-182.9 + \frac{(150 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right) - 20 \text{ kJ/s} = 510 \text{ kW}$$

(b) Under steady conditions, the rate form of the entropy balance for the turbine simplifies to

$$\begin{aligned} \dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} &= \Delta \dot{S}_{\text{system}} \rvert_{T_0} = 0 \\ \dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{\text{out}}}{T_{b,\text{out}}} + \dot{S}_{\text{gen}} &= 0 \rightarrow \dot{S}_{\text{gen}} = \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{\text{out}}}{T_0} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = T_0 \left(\dot{m}(s_2 - s_1) + \frac{\dot{Q}_{\text{out}}}{T_0} \right)$$

where $s_2 - s_1 = R(Z_{s_1} - Z_{s_2}) + (s_2 - s_1)_{\text{ideal}}$

$$\text{and } (s_2 - s_1)_{\text{ideal}} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = 0.5203 \ln \frac{450}{800} - 0.2081 \ln \frac{1.5}{9} = 0.0735 \text{ kJ/kg} \cdot \text{K}$$

$$\text{Thus, } s_2 - s_1 = R(Z_{s_1} - Z_{s_2}) + (s_2 - s_1)_{\text{ideal}} = (0.2081)[0 - (0.013)] + 0.0735 = 0.0708 \text{ kJ/kg} \cdot \text{K}$$

Substituting,

$$\dot{X}_{\text{destroyed}} = (298 \text{ K}) \left((3 \text{ kg/s})(0.0708 \text{ kJ/kg} \cdot \text{K}) + \frac{20 \text{ kW}}{298 \text{ K}} \right) = 83.3 \text{ kW}$$

12-97 Problem 12-96 is reconsidered. The problem is to be solved assuming steam is the working fluid by using the generalized chart method and EES data for steam. The power output and the exergy destruction rate for these two calculation methods against the turbine exit pressure are to be plotted.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

12-98 An adiabatic storage tank that is initially evacuated is connected to a supply line that carries nitrogen. A valve is opened, and nitrogen flows into the tank. The final temperature in the tank is to be determined by treating nitrogen as an ideal gas and using the generalized charts, and the results are to be compared to the given actual value.

Assumptions 1 Uniform flow conditions exist. 2 Kinetic and potential energies are negligible.

Analysis We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

$$\text{Mass balance: } m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_i = m_2 \quad (\text{since } m_{\text{out}} = m_{\text{initial}} = 0)$$

$$\text{Energy balance: } E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \rightarrow 0 + m_i h_i = m_2 u_2$$

Combining the two balances: $u_2 = h_i$

(a) From the ideal gas property table of nitrogen, at 225 K we read

$$\bar{u}_2 = \bar{h}_i = \bar{h}_{@225\text{ K}} = 6,537 \text{ kJ/kmol}$$

The temperature that corresponds to this \bar{u}_2 value is

$$T_2 = 314.8 \text{ K} \quad (7.4\% \text{ error})$$

(b) Using the generalized enthalpy departure chart, h_i is determined to be

$$\left. \begin{aligned} T_{R,i} &= \frac{T_i}{T_{cr}} = \frac{225}{126.2} = 1.78 \\ P_{R,i} &= \frac{P_i}{P_{cr}} = \frac{10}{3.39} = 2.95 \end{aligned} \right\} Z_{h,i} = \frac{\bar{h}_{i,\text{ideal}} - \bar{h}_i}{R_u T_{cr}} = 0.9 \quad (\text{Fig. A-29})$$

Thus,

$$\bar{h}_i = \bar{h}_{i,\text{ideal}} - 0.9 R_u T_{cr} = 6,537 - (0.9)(8.314)(126.2) = 5,593 \text{ kJ/kmol}$$

and

$$\bar{u}_2 = \bar{h}_i = 5,593 \text{ kJ/kmol}$$

Try $T_2 = 280 \text{ K}$. Then at $P_{R2} = 2.95$ and $T_{R2} = 2.22$ we read $Z_2 = 0.98$ and $(\bar{h}_{2,\text{ideal}} - \bar{h}_2) / R_u T_{cr} = 0.55$

Thus,

$$\bar{h}_2 = \bar{h}_{2,\text{ideal}} - 0.55 R_u T_{cr} = 8,141 - (0.55)(8.314)(126.2) = 7,564 \text{ kJ/kmol}$$

$$\bar{u}_2 = \bar{h}_2 - Z R_u T_2 = 7,564 - (0.98)(8.314)(280) = 5,283 \text{ kJ/kmol}$$

Try $T_2 = 300 \text{ K}$. Then at $P_{R2} = 2.95$ and $T_{R2} = 2.38$ we read $Z_2 = 1.0$ and $(\bar{h}_{2,\text{ideal}} - \bar{h}_2) / R_u T_{cr} = 0.50$

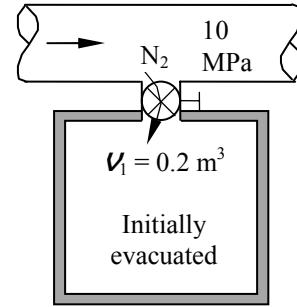

Thus,

$$\bar{h}_2 = \bar{h}_{2,\text{ideal}} - 0.50 R_u T_{cr} = 8,723 - (0.50)(8.314)(126.2) = 8,198 \text{ kJ/kmol}$$

$$\bar{u}_2 = \bar{h}_2 - Z R_u T_2 = 8,198 - (1.0)(8.314)(300) = 5,704 \text{ kJ/kmol}$$

By linear interpolation,

$$T_2 = 294.7 \text{ K} \quad (0.6\% \text{ error})$$

12-99E Methane is to be adiabatically and reversibly compressed in a steady-flow device. The specific work required for this compression is to be determined using the departure charts and treating the methane as an ideal gas with temperature variable specific heats.

Properties The properties of methane are (Table A-1E)

$$M = 16.043 \text{ lbm/lbmol}, R = 0.1238 \text{ Btu/lbm}\cdot\text{R}, T_{\text{cr}} = 343.9 \text{ R}, P_{\text{cr}} = 673 \text{ psia}$$

Analysis The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. When the expression of Table A-2Ec is substituted for c_p and the integration performed, we obtain

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left(\frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \end{aligned}$$

Substituting,

$$\begin{aligned} 0 &= 4.75 \ln \frac{T_2}{560} + 0.006666(T_2 - 560) + \frac{0.09352 \times 10^{-5}}{2}(T_2^2 - 560^2) \\ &\quad - \frac{0.4510 \times 10^{-9}}{3}(T_2^3 - 560^3) - (1.9858) \ln \frac{50}{50} \end{aligned}$$

Solving this equation by EES or an iterative solution gives

$$T_2 = 892 \text{ R}$$

When an energy balance is applied to the compressor, it becomes

$$\begin{aligned} \bar{w}_{\text{in}} &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \int_1^2 c_p dT = \int_1^2 (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 4.75(892 - 560) + \frac{0.006666}{2}(892^2 - 560^2) + \frac{0.09352 \times 10^{-5}}{3}(892^3 - 560^3) \\ &\quad - \frac{0.4510 \times 10^{-9}}{4}(892^4 - 560^4) \\ &= 3290 \text{ Btu/lbmol} \end{aligned}$$

The work input per unit mass basis is

$$w_{\text{in}} = \frac{\bar{w}_{\text{in}}}{M} = \frac{3290 \text{ Btu/lbmol}}{16.043 \text{ lbm/lbmol}} = \mathbf{205.1 \text{ Btu/lbm}}$$

The enthalpy departures of propane at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

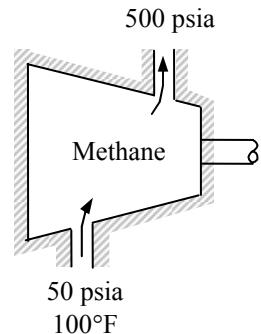

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{560}{343.9} = 1.628 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{50}{673} = 0.0743 \end{aligned} \right\} \rightarrow Z_{h1} = 0.0332$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{892}{343.9} = 2.594 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{500}{673} = 0.743 \end{aligned} \right\} \rightarrow Z_{h2} = 0.0990$$

The work input is determined to be

$$\begin{aligned} w_{\text{in}} &= h_2 - h_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= 205.1 \text{ Btu/lbm} - (0.1238 \text{ Btu/lbm}\cdot\text{R})(343.9 \text{ R})(0.0990 - 0.0332) \\ &= \mathbf{202.3 \text{ Btu/lbm}} \end{aligned}$$

12-100 The volume expansivity of water is given. The change in volume of water when it is heated at constant pressure is to be determined.

Properties The volume expansivity of water is given to be $0.207 \times 10^{-6} \text{ K}^{-1}$ at 20°C .

Analysis We take $\nu = \nu(P, T)$. Its total differential is

$$d\nu = \left(\frac{\partial \nu}{\partial T} \right)_P dT + \left(\frac{\partial \nu}{\partial P} \right)_T dP$$

which, for a constant pressure process, reduces to

$$d\nu = \left(\frac{\partial \nu}{\partial T} \right)_P dT$$

Dividing by ν and using the definition of β ,

$$\frac{d\nu}{\nu} = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T} \right)_P dT = \beta dT$$

Taking β to be a constant, integration from 1 to 2 yields

$$\ln \frac{\nu_2}{\nu_1} = \beta(T_2 - T_1)$$

or

$$\frac{\nu_2}{\nu_1} = \exp[\beta(T_2 - T_1)]$$

Substituting the given values and noting that for a fixed mass $\nu_2/\nu_1 = v_2/v_1$,

$$\begin{aligned} \nu_2 &= \nu_1 \exp[\beta(T_2 - T_1)] = (0.5 \text{ m}^3) \exp[(0.207 \times 10^{-6} \text{ K}^{-1})(50 - 10)^\circ\text{C}] \\ &= 0.50000414 \text{ m}^3 \end{aligned}$$

Therefore,

$$\Delta \nu = \nu_2 - \nu_1 = 0.50000414 - 0.5 = 0.00000414 \text{ m}^3 = \mathbf{4.14 \text{ cm}^3}$$

12-101 The work done by the refrigerant 134a as it undergoes an isothermal process in a closed system is to be determined using the tabular (EES) data and the generalized charts.

Analysis The solution using EES built-in property data is as follows:

$$\begin{aligned} T_1 &= 40^\circ\text{C} \quad \left\{ u_1 = 106.37 \text{ kJ/kg} \right. \\ P_1 &= 2 \text{ MPa} \quad \left. s_1 = 0.3916 \text{ kJ/kg.K} \right\} \end{aligned}$$

$$\begin{aligned} T_2 &= 40^\circ\text{C} \quad \left\{ u_2 = 264.25 \text{ kJ/kg} \right. \\ P_2 &= 0.1 \text{ MPa} \quad \left. s_2 = 1.1484 \text{ kJ/kg.K} \right\} \end{aligned}$$

$$\Delta s_{\text{EES}} = s_2 - s_1 = 1.1484 - 0.3916 = 0.7568 \text{ kJ/kg.K}$$

$$q_{\text{EES}} = T_1 \Delta s_{\text{EES}} = (40 + 273.15 \text{ K})(0.7568 \text{ kJ/kg.K}) = 237.00 \text{ kJ/kg}$$

$$w_{\text{EES}} = q_{\text{EES}} - (u_2 - u_1) = 237.00 - (264.25 - 106.37) = \mathbf{79.1 \text{ kJ/kg}}$$

For the generalized chart solution we first determine the following factors using EES as

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{313.2}{374.2} = 0.8369 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{2}{4.059} = 0.4927 \end{aligned} \right\} \longrightarrow Z_1 = 0.08357, Z_{h1} = 4.82 \text{ and } Z_{s1} = 5.147$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{313.2}{374.2} = 0.8369 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{0.1}{4.059} = 0.02464 \end{aligned} \right\} \longrightarrow Z_2 = 0.9857, Z_{h2} = 0.03396 \text{ and } Z_{s2} = 0.02635$$

Then,

$$\Delta h_1 = Z_{h1} R T_{cr} = (4.82)(0.08148 \text{ kJ/kg.K})(374.2 \text{ K}) = 146.97 \text{ kJ/kg}$$

$$\Delta s_1 = Z_{s1} R = (5.147)(0.08148 \text{ kJ/kg.K}) = 0.4194 \text{ kJ/kg.K}$$

$$\Delta h_2 = Z_{h2} R T_{cr} = (0.03396)(0.08148 \text{ kJ/kg.K})(374.2 \text{ K}) = 1.04 \text{ kJ/kg}$$

$$\Delta s_2 = Z_{s2} R = (0.02635)(0.08148 \text{ kJ/kg.K}) = 0.002147 \text{ kJ/kg.K}$$

$$\Delta s_{\text{ideal}} = R \ln \frac{P_2}{P_1} = (0.08148 \text{ kJ/kg.K}) \ln \left(\frac{0.1}{2} \right) = 0.2441 \text{ kJ/kg.K}$$

$$\Delta s_{\text{chart}} = \Delta s_{\text{ideal}} - (\Delta s_2 - \Delta s_1) = 0.2441 - (0.002147 - 0.4194) = 0.6613 \text{ kJ/kg.K}$$

$$q_{\text{chart}} = T_1 \Delta s_{\text{chart}} = (40 + 273.15 \text{ K})(0.6613 \text{ kJ/kg.K}) = 207.09 \text{ kJ/kg}$$

$$\begin{aligned} \Delta u_{\text{chart}} &= \Delta h_{\text{ideal}} - (\Delta h_2 - \Delta h_1) - (Z_2 R T_2 - Z_1 R T_1) \\ &= 0 - (1.04 - 146.97) - [(0.9857)(0.08148)(313.2) - (0.08357)(0.08148)(313.2)] = 122.92 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{chart}} = q_{\text{chart}} - \Delta u_{\text{chart}} = 207.09 - 122.92 = \mathbf{84.2 \text{ kJ/kg}}$$

The copy of the EES solution of this problem is given next.

12-102 The heat transfer, work, and entropy changes of methane during a process in a piston-cylinder device are to be determined assuming ideal gas behavior, using generalized charts, and real fluid (EES) data.

Analysis The ideal gas solution: (Properties are obtained from EES)

State 1:

$$T_1 = 100^\circ\text{C} \longrightarrow h_1 = -4492 \text{ kJ/kg}$$

$$T_1 = 100^\circ\text{C}, P_1 = 4 \text{ MPa} \longrightarrow s_1 = 10.22 \text{ kJ/kg.K}$$

$$u_1 = h_1 - RT_1 = (-4492) - (0.5182)(100 + 273.15) = -4685 \text{ kJ/kg}$$

$$\nu_1 = R \frac{T_1}{P_1} = (0.5182 \text{ kJ/kg.K}) \left(\frac{100 + 273.15 \text{ K}}{4000 \text{ kPa}} \right) = 0.04834 \text{ m}^3/\text{kg}$$

State 2:

$$T_2 = 350^\circ\text{C} \longrightarrow h_2 = -3770 \text{ kJ/kg}$$

$$T_2 = 350^\circ\text{C}, P_2 = 4 \text{ MPa} \longrightarrow s_2 = 11.68 \text{ kJ/kg.K}$$

$$u_2 = h_2 - RT_2 = (-3770) - (0.5182)(350 + 273.15) = -4093 \text{ kJ/kg}$$

$$\nu_2 = R \frac{T_2}{P_2} = (0.5182 \text{ kJ/kg.K}) \left(\frac{350 + 273.15 \text{ K}}{4000 \text{ kPa}} \right) = 0.08073 \text{ m}^3/\text{kg}$$

$$w_{\text{ideal}} = P(\nu_2 - \nu_1) = (4000 \text{ kPa})(0.08073 - 0.04834) \text{ m}^3/\text{kg} = \mathbf{129.56 \text{ kJ/kg}}$$

$$q_{\text{ideal}} = w_{\text{ideal}} + (u_2 - u_1) = 129.56 + [(-4093) - (-4685)] = \mathbf{721.70 \text{ kJ/kg}}$$

$$\Delta s_{\text{ideal}} = s_2 - s_1 = 11.68 - 10.22 = \mathbf{1.46 \text{ kJ/kg.K}}$$

For the generalized chart solution we first determine the following factors using EES as

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{304.2} = 1.227 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{4}{7.39} = 0.5413 \end{aligned} \right\} \longrightarrow Z_1 = 0.9023, Z_{h1} = 0.4318 \text{ and } Z_{s1} = 0.2555$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{623}{304.2} = 2.048 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{4}{7.39} = 0.5413 \end{aligned} \right\} \longrightarrow Z_2 = 0.995, Z_{h2} = 0.1435 \text{ and } Z_{s2} = 0.06446$$

State 1:

$$\Delta h_1 = Z_{h1} RT_{\text{cr}} = (0.4318)(0.5182 \text{ kJ/kg.K})(304.2 \text{ K}) = 68.07 \text{ kJ/kg}$$

$$h_1 = h_{1,\text{ideal}} - \Delta h_1 = (-4492) - 68.07 = -4560 \text{ kJ/kg}$$

$$u_1 = h_1 - Z_1 RT_1 = (-4560) - (0.9023)(0.5182)(373.15) = -4734 \text{ kJ/kg}$$

$$\nu_1 = Z_1 R \frac{T_1}{P_1} = (0.9023)(0.5182) \frac{373.15}{4000} = 0.04362 \text{ m}^3/\text{kg}$$

$$\Delta s_1 = Z_{s1} R = (0.2555)(0.5182 \text{ kJ/kg.K}) = 0.1324 \text{ kJ/kg.K}$$

$$s_1 = s_{1,\text{ideal}} - \Delta s_1 = 10.22 - 0.1324 = 10.09 \text{ kJ/kg.K}$$

State 2:

$$\Delta h_2 = Z_{h2} RT_{\text{cr}} = (0.1435)(0.5182 \text{ kJ/kg.K})(304.2 \text{ K}) = 22.62 \text{ kJ/kg}$$

$$h_2 = h_{2,\text{ideal}} - \Delta h_2 = (-3770) - 22.62 = -3793 \text{ kJ/kg}$$

$$u_2 = h_2 - Z_2 RT_2 = (-3793) - (0.995)(0.5182)(623.15) = -4114 \text{ kJ/kg}$$

$$\nu_2 = Z_2 R \frac{T_2}{P_2} = (0.995)(0.5182) \frac{623.15}{4000} = 0.08033 \text{ m}^3/\text{kg}$$

$$\Delta s_2 = Z_{s2} R = (0.06446)(0.5182 \text{ kJ/kg.K}) = 0.03341 \text{ kJ/kg.K}$$

$$s_2 = s_{2,\text{ideal}} - \Delta s_2 = 11.68 - 0.03341 = 11.65 \text{ kJ/kg.K}$$

Then,

$$w_{\text{chart}} = P(\nu_2 - \nu_1) = (4000 \text{ kPa})(0.08033 - 0.04362) \text{ m}^3/\text{kg} = \mathbf{146.84 \text{ kJ/kg}}$$

$$q_{\text{chart}} = w_{\text{chart}} + (u_2 - u_1) = 146.84 + [(-4114) - (-4734)] = \mathbf{766.84 \text{ kJ/kg}}$$

$$\Delta s_{\text{chart}} = s_2 - s_1 = 11.65 - 10.09 = \mathbf{1.56 \text{ kJ/kg}}$$

The solution using EES built-in property data is as follows:

$$\left. \begin{array}{l} T_1 = 100^\circ\text{C} \\ P_1 = 4 \text{ MPa} \end{array} \right\} \begin{array}{l} \nu_1 = 0.04717 \text{ m}^3/\text{kg} \\ u_1 = -39.82 \text{ kJ/kg} \\ s_1 = -1.439 \text{ kJ/kg.K} \end{array}$$

$$\left. \begin{array}{l} T_2 = 350^\circ\text{C} \\ P_2 = 4 \text{ MPa} \end{array} \right\} \begin{array}{l} \nu_2 = 0.08141 \text{ m}^3/\text{kg} \\ u_2 = 564.52 \text{ kJ/kg} \\ s_2 = 0.06329 \text{ kJ/kg.K} \end{array}$$

$$w_{\text{EES}} = P(\nu_2 - \nu_1) = (4000 \text{ kPa})(0.08141 - 0.04717) \text{ m}^3/\text{kg} = \mathbf{136.96 \text{ kJ/kg}}$$

$$q_{\text{EES}} = w_{\text{EES}} + (u_2 - u_1) = 136.97 + [564.52 - (-39.82)] = \mathbf{741.31 \text{ kJ/kg}}$$

$$\Delta s_{\text{EES}} = s_2 - s_1 = 0.06329 - (-1.439) = \mathbf{1.50 \text{ kJ/kg}}$$

12-103E Methane is compressed steadily. The entropy change and the specific work required are to be determined using the departure charts and the property tables.

Properties The properties of methane are (Table A-1E)

$$M = 16.043 \text{ lbm/lbmol}, T_{\text{cr}} = 343.9 \text{ R}, P_{\text{cr}} = 673 \text{ psia}, c_p = 0.532 \text{ Btu/lbm} \cdot \text{R}, R = 0.1238 \text{ Btu/lbm} \cdot \text{R}$$

Analysis (a) Using empirical correlation for the c_p of methane as given in Table A-2Ec gives

$$\begin{aligned}\bar{h}_2 - \bar{h}_1 &= \int c_p dT = \int (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 4.750(1000) + \frac{0.6666 \times 10^{-2}}{2}(1560^2 - 560^2) + \frac{0.09352 \times 10^{-5}}{3}(1560^3 - 560^3) \\ &\quad + \frac{-0.4510 \times 10^{-9}}{4}(1560^4 - 560^4) \\ &= 12,288 \text{ Btu/lbmol} \cdot \text{R}\end{aligned}$$

The work input is equal to the enthalpy change. The enthalpy change per unit mass is

$$w_{in} = h_2 - h_1 = \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{12,288 \text{ Btu/lbmol}}{16.043 \text{ lbm/lbmol}} = \mathbf{765.9 \text{ Btu/lbm}}$$

Similarly, the entropy change is given by

$$\begin{aligned}(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left(\frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \\ &= 4.750 \ln \frac{1560}{560} + 0.6666 \times 10^{-2}(1560 - 560) + \frac{0.09352 \times 10^{-5}}{2}(1560^2 - 560^2) \\ &\quad + \frac{-0.4510 \times 10^{-9}}{3}(1560^3 - 560^3) - (1.9858) \ln \frac{500}{50} \\ &= 7.407 \text{ Btu/lbmol} \cdot \text{R}\end{aligned}$$

The entropy change per unit mass is

$$(s_2 - s_1)_{\text{ideal}} = \frac{(\bar{s}_2 - \bar{s}_1)_{\text{ideal}}}{M} = \frac{7.407 \text{ Btu/lbmol} \cdot \text{R}}{16.043 \text{ lbm/lbmol}} = \mathbf{0.4617 \text{ Btu/lbm} \cdot \text{R}}$$

(b) The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES. We used EES.)

$$\left. \begin{aligned}T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{560}{343.9} = 1.63 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{50}{673} = 0.0743\end{aligned} \right\} \rightarrow Z_{h1} = 0.03313 \text{ and } Z_{s1} = 0.01617$$

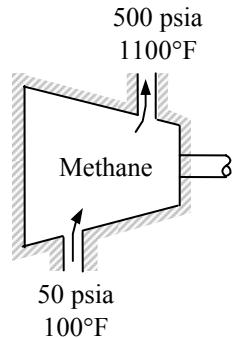

and

$$\left. \begin{aligned}T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{1560}{343.9} = 4.54 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{500}{673} = 0.743\end{aligned} \right\} \rightarrow Z_{h2} = 0 \text{ and } Z_{s2} = 0.00695$$

The work input and entropy changes are

$$\begin{aligned}w_{in} &= h_2 - h_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= 765.9 - (0.1238)(343.9)(0 - 0.03313) = \mathbf{767.4 \text{ Btu/lbm}}\end{aligned}$$

$$\begin{aligned}s_2 - s_1 &= (s_2 - s_1)_{\text{ideal}} - R(Z_{s2} - Z_{s1}) \\ &= 0.4617 - (0.1238)(0.00695 - 0.01617) = \mathbf{0.4628 \text{ Btu/lbm} \cdot \text{R}}\end{aligned}$$

12-104E Methane is compressed in a steady-flow device. The second-law efficiency of the compression process is to be determined.

Analysis The reversible work input to the compressor is determined from

$$w_{\text{rev}} = h_2 - h_1 - T_0(s_2 - s_1) = 767.4 \text{ Btu/lbm} - (537 \text{ R})(0.4628 \text{ Btu/lbm} \cdot \text{R}) = 518.8 \text{ Btu/lbm}$$

The second-law efficiency of the compressor is

$$\eta_{\text{II}} = \frac{w_{\text{rev}}}{w_{\text{actual}}} = \frac{518.8}{767.4} = 0.676 = \mathbf{67.6\%}$$

Fundamentals of Engineering (FE) Exam Problems

12-105 A substance whose Joule-Thomson coefficient is negative is throttled to a lower pressure. During this process, (select the correct statement)

- (a) the temperature of the substance will increase.
- (b) the temperature of the substance will decrease.
- (c) the entropy of the substance will remain constant.
- (d) the entropy of the substance will decrease.
- (e) the enthalpy of the substance will decrease.

Answer (a) the temperature of the substance will increase.

12-106 Consider the liquid-vapor saturation curve of a pure substance on the P - T diagram. The magnitude of the slope of the tangent line to this curve at a temperature T (in Kelvin) is

- (a) proportional to the enthalpy of vaporization h_{fg} at that temperature,
- (b) proportional to the temperature T ,
- (c) proportional to the square of the temperature T ,
- (d) proportional to the volume change v_{fg} at that temperature,
- (e) inversely proportional to the entropy change s_{fg} at that temperature,

Answer (a) proportional to the enthalpy of vaporization h_{fg} at that temperature,

12-107 Based on the generalized charts, the error involved in the enthalpy of CO_2 at 300 K and 5 MPa if it is assumed to be an ideal gas is

- (a) 0
- (b) 9%
- (c) 16%
- (d) 22%
- (e) 27%

Answer (e) 27%

12-108 Based on data from the refrigerant-134a tables, the Joule-Thompson coefficient of refrigerant-134a at 0.8 MPa and 100°C is approximately

Answer (c) $11^{\circ}\text{C}/\text{MPa}$

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

T1=100 "C"

$$P_1=800 \text{ "kPa"}$$

h1=ENTHALPY(R134a,T=T1,P=P1)

Tlow=TEMPERATURE(R134a,h=h1,P=P1+100)

Thigh=TEMPERATURE(R134a,h=h1,P=P1-100)

$$JT = (T_{low} - T_{high}) / 200$$

12-109 For a gas whose equation of state is $P(v - b) = RT$, the specific heat difference $c_p - c_v$ is equal to

Answer (a) R

Solution The general relation for the specific heat difference $c_p - c_v$ is

$$c_p - c_v = -T \left(\frac{\partial v}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial v} \right)_T$$

For the given gas, $P(\nu - b) = RT$. Then,

$$\nu = \frac{RT}{P} + b \longrightarrow \left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

$$P = \frac{RT}{\nu - b} \longrightarrow \left(\frac{\partial P}{\partial \nu} \right)_T = - \frac{RT}{(\nu - b)^2} = - \frac{P}{\nu - b}$$

Substituting,

$$c_p - c_v = -T \left(\frac{R}{P} \right)^2 \left(-\frac{P}{v-b} \right) = \frac{TR^2}{P(v-b)} = R$$

Composition of Gas Mixtures

13-1C The ratio of the mass of a component to the mass of the mixture is called the mass fraction (mf), and the ratio of the mole number of a component to the mole number of the mixture is called the mole fraction (y).

13-2C The mass fractions will be identical, but the mole fractions will not.

13-3C Yes.

13-4C Yes, because both CO_2 and N_2O has the same molar mass, $M = 44 \text{ kg/kmol}$.

13-5C No. We can do this only when each gas has the same mole fraction.

13-6C It is the average or the equivalent molar mass of the gas mixture. No.

13-7 From the definition of mass fraction,

$$mf_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \left(\frac{M_i}{M_m} \right)$$

13-8 A mixture consists of two gases. Relations for mole fractions when mass fractions are known are to be obtained .

Analysis The mass fractions of *A* and *B* are expressed as

$$\text{mf}_A = \frac{m_A}{m_m} = \frac{N_A M_A}{N_m M_m} = y_A \frac{M_A}{M_m} \quad \text{and} \quad \text{mf}_B = y_B \frac{M_B}{M_m}$$

Where *m* is mass, *M* is the molar mass, *N* is the number of moles, and *y* is the mole fraction. The apparent molar mass of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{N_A M_A + N_B M_B}{N_m} = y_A M_A + y_B M_B$$

Combining the two equation above and noting that $y_A + y_B = 1$ gives the following convenient relations for converting mass fractions to mole fractions,

$$y_A = \frac{M_B}{M_A(1/\text{mf}_A - 1) + M_B} \quad \text{and} \quad y_B = 1 - y_A$$

which are the desired relations.

13-9 The definitions for the mass fraction, weight, and the weight fractions are

$$(\text{mf})_i = \frac{m_i}{m_{\text{total}}}$$

$$W = mg$$

$$(\text{wf})_i = \frac{W_i}{W_{\text{total}}}$$

Since the total system consists of one mass unit, the mass of the *i*th component in this mixture is *m_i*. The weight of this one component is then

$$W_i = g(\text{mf})_i$$

Hence, the weight fraction for this one component is

$$(\text{wf})_i = \frac{g(\text{mf})_i}{\sum g(\text{mf})_i} = (\text{mf})_i$$

13-10E The moles of components of a gas mixture are given. The mole fractions and the apparent molecular weight are to be determined.

Properties The molar masses of He, O₂, N₂, and H₂O are 4.0, 32.0, 28.0 and 18.0 lbm/lbmol, respectively (Table A-1).

Analysis The total mole number of the mixture is

$$N_m = N_{\text{He}} + N_{\text{O}_2} + N_{\text{H}_2\text{O}} + N_{\text{N}_2} = 3 + 1.5 + 0.3 + 2.5 = 7.3 \text{ lbmol}$$

and the mole fractions are

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_m} = \frac{3 \text{ lbmol}}{7.3 \text{ lbmol}} = \mathbf{0.411}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{1.5 \text{ lbmol}}{7.3 \text{ lbmol}} = \mathbf{0.206}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{0.3 \text{ lbmol}}{7.3 \text{ lbmol}} = \mathbf{0.0411}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{2.5 \text{ lbmol}}{7.3 \text{ lbmol}} = \mathbf{0.343}$$

3 lbmol He
1.5 lbmol O ₂
0.3 lbmol H ₂ O
2.5 lbmol N ₂

The total mass of the mixture is

$$\begin{aligned} m_m &= m_{\text{He}} + m_{\text{O}_2} + m_{\text{H}_2\text{O}} + m_{\text{N}_2} \\ &= N_{\text{He}}M_{\text{He}} + N_{\text{O}_2}M_{\text{O}_2} + N_{\text{H}_2\text{O}}M_{\text{H}_2\text{O}} + N_{\text{N}_2}M_{\text{N}_2} \\ &= (3 \text{ lbm})(4 \text{ lbm/lbmol}) + (1.5 \text{ lbm})(32 \text{ lbm/lbmol}) + (0.3 \text{ lbm})(18 \text{ lbm/lbmol}) + (2.5 \text{ lbm})(28 \text{ lbm/lbmol}) \\ &= 135.4 \text{ lbm} \end{aligned}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{135.4 \text{ lbm}}{7.3 \text{ lbmol}} = \mathbf{18.6 \text{ lbm/lbmol}}$$

13-11 The masses of the constituents of a gas mixture are given. The mass fractions, the mole fractions, the average molar mass, and gas constant are to be determined.

Properties The molar masses of O₂, N₂, and CO₂ are 32.0, 28.0 and 44.0 kg/kmol, respectively (Table A-1)

Analysis (a) The total mass of the mixture is

$$m_m = m_{O_2} + m_{N_2} + m_{CO_2} = 5 \text{ kg} + 8 \text{ kg} + 10 \text{ kg} = 23 \text{ kg}$$

Then the mass fraction of each component becomes

$$mf_{O_2} = \frac{m_{O_2}}{m_m} = \frac{5 \text{ kg}}{23 \text{ kg}} = 0.217$$

$$mf_{N_2} = \frac{m_{N_2}}{m_m} = \frac{8 \text{ kg}}{23 \text{ kg}} = 0.348$$

$$mf_{CO_2} = \frac{m_{CO_2}}{m_m} = \frac{10 \text{ kg}}{23 \text{ kg}} = 0.435$$

5 kg O₂
8 kg N₂
10 kg CO₂

(b) To find the mole fractions, we need to determine the mole numbers of each component first,

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{5 \text{ kg}}{32 \text{ kg/kmol}} = 0.156 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{8 \text{ kg}}{28 \text{ kg/kmol}} = 0.286 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{10 \text{ kg}}{44 \text{ kg/kmol}} = 0.227 \text{ kmol}$$

Thus,

$$N_m = N_{O_2} + N_{N_2} + N_{CO_2} = 0.156 \text{ kmol} + 0.286 \text{ kmol} + 0.227 \text{ kmol} = 0.669 \text{ kmol}$$

and

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.156 \text{ kmol}}{0.669 \text{ kmol}} = 0.233$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.286 \text{ kmol}}{0.669 \text{ kmol}} = 0.428$$

$$y_{CO_2} = \frac{N_{CO_2}}{N_m} = \frac{0.227 \text{ kmol}}{0.669 \text{ kmol}} = 0.339$$

(c) The average molar mass and gas constant of the mixture are determined from their definitions:

$$M_m = \frac{m_m}{N_m} = \frac{23 \text{ kg}}{0.669 \text{ kmol}} = 34.4 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{34.4 \text{ kg/kmol}} = 0.242 \text{ kJ/kg} \cdot \text{K}$$

13-12 The mass fractions of the constituents of a gas mixture are given. The mole fractions of the gas and gas constant are to be determined.

Properties The molar masses of CH₄, and CO₂ are 16.0 and 44.0 kg/kmol, respectively (Table A-1)

Analysis For convenience, consider 100 kg of the mixture. Then the number of moles of each component and the total number of moles are

$$m_{\text{CH}_4} = 75 \text{ kg} \longrightarrow N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ kg}}{16 \text{ kg/kmol}} = 4.688 \text{ kmol}$$

$$m_{\text{CO}_2} = 25 \text{ kg} \longrightarrow N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.568 \text{ kmol}$$

$$N_m = N_{\text{CH}_4} + N_{\text{CO}_2} = 4.688 \text{ kmol} + 0.568 \text{ kmol} = 5.256 \text{ kmol}$$

mass
75% CH ₄
25% CO ₂

Then the mole fraction of each component becomes

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.688 \text{ kmol}}{5.256 \text{ kmol}} = 0.892 \text{ or } \mathbf{89.2\%}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.568 \text{ kmol}}{5.256 \text{ kmol}} = 0.108 \text{ or } \mathbf{10.8\%}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{5.256 \text{ kmol}} = 19.03 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{19.03 \text{ kg/kmol}} = \mathbf{0.437 \text{ kJ/kg} \cdot \text{K}}$$

13-13 The mole numbers of the constituents of a gas mixture are given. The mass of each gas and the apparent gas constant are to be determined.

Properties The molar masses of H₂, and N₂ are 2.0 and 28.0 kg/kmol, respectively (Table A-1)

Analysis The mass of each component is determined from

$$N_{\text{H}_2} = 5 \text{ kmol} \longrightarrow m_{\text{H}_2} = N_{\text{H}_2} M_{\text{H}_2} = (5 \text{ kmol})(2.0 \text{ kg/kmol}) = \mathbf{10 \text{ kg}}$$

$$N_{\text{N}_2} = 4 \text{ kmol} \longrightarrow m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (4 \text{ kmol})(28 \text{ kg/kmol}) = \mathbf{112 \text{ kg}}$$

5 kmol H ₂
4 kmol N ₂

The total mass and the total number of moles are

$$m_m = m_{\text{H}_2} + m_{\text{N}_2} = 10 \text{ kg} + 112 \text{ kg} = 122 \text{ kg}$$

$$N_m = N_{\text{H}_2} + N_{\text{N}_2} = 5 \text{ kmol} + 4 \text{ kmol} = 9 \text{ kmol}$$

5 kmol H ₂
4 kmol N ₂

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{122 \text{ kg}}{9 \text{ kmol}} = 13.56 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{13.56 \text{ kg/kmol}} = \mathbf{0.613 \text{ kJ/kg} \cdot \text{K}}$$

13-14 The mass fractions of the constituents of a gas mixture are given. The volumetric analysis of the mixture and the apparent gas constant are to be determined.

Properties The molar masses of O₂, N₂ and CO₂ are 32.0, 28, and 44.0 kg/kmol, respectively (Table A-1)

Analysis For convenience, consider 100 kg of the mixture. Then the number of moles of each component and the total number of moles are

$$m_{O_2} = 20 \text{ kg} \longrightarrow N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{20 \text{ kg}}{32 \text{ kg/kmol}} = 0.625 \text{ kmol}$$

$$m_{N_2} = 30 \text{ kg} \longrightarrow N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{30 \text{ kg}}{28 \text{ kg/kmol}} = 1.071 \text{ kmol}$$

$$m_{CO_2} = 50 \text{ kg} \longrightarrow N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{50 \text{ kg}}{44 \text{ kg/kmol}} = 1.136 \text{ kmol}$$

mass
20% O ₂
30% N ₂
50% CO ₂

$$N_m = N_{O_2} + N_{N_2} + N_{CO_2} = 0.625 + 1.071 + 1.136 = 2.832 \text{ kmol}$$

Noting that the volume fractions are same as the mole fractions, the volume fraction of each component becomes

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.625 \text{ kmol}}{2.832 \text{ kmol}} = 0.221 \text{ or } \mathbf{22.1\%}$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{1.071 \text{ kmol}}{2.832 \text{ kmol}} = 0.378 \text{ or } \mathbf{37.8\%}$$

$$y_{CO_2} = \frac{N_{CO_2}}{N_m} = \frac{1.136 \text{ kmol}}{2.832 \text{ kmol}} = 0.401 \text{ or } \mathbf{40.1\%}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{2.832 \text{ kmol}} = 35.31 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{35.31 \text{ kg/kmol}} = \mathbf{0.235 \text{ kJ/kg} \cdot \text{K}}$$

P-v-T Behavior of Gas Mixtures

13-15C Normally yes. Air, for example, behaves as an ideal gas in the range of temperatures and pressures at which oxygen and nitrogen behave as ideal gases.

13-16C The pressure of a gas mixture is equal to the sum of the pressures each gas would exert if existed alone at the mixture temperature and volume. This law holds exactly for ideal gas mixtures, but only approximately for real gas mixtures.

13-17C The volume of a gas mixture is equal to the sum of the volumes each gas would occupy if existed alone at the mixture temperature and pressure. This law holds exactly for ideal gas mixtures, but only approximately for real gas mixtures.

13-18C The $P\text{-}\nu\text{-}T$ behavior of a component in an ideal gas mixture is expressed by the ideal gas equation of state using the properties of the individual component instead of the mixture, $P_i\nu_i = R_iT_i$. The $P\text{-}\nu\text{-}T$ behavior of a component in a real gas mixture is expressed by more complex equations of state, or by $P_i\nu_i = Z_iR_iT_i$, where Z_i is the compressibility factor.

13-19C Component pressure is the pressure a component would exert if existed alone at the mixture temperature and volume. Partial pressure is the quantity y_iP_m , where y_i is the mole fraction of component i . These two are identical for ideal gases.

13-20C Component volume is the volume a component would occupy if existed alone at the mixture temperature and pressure. Partial volume is the quantity $y_i\nu_m$, where y_i is the mole fraction of component i . These two are identical for ideal gases.

13-21C The one with the highest mole number.

13-22C The partial pressures will decrease but the pressure fractions will remain the same.

13-23C The partial pressures will increase but the pressure fractions will remain the same.

13-24C No. The correct expression is “the volume of a gas mixture is equal to the sum of the volumes each gas would occupy if existed alone at the mixture temperature and pressure.”

13-25C No. The correct expression is “the temperature of a gas mixture is equal to the temperature of the individual gas components.”

13-26C Yes, it is correct.

13-27C With Kay's rule, a real-gas mixture is treated as a pure substance whose critical pressure and temperature are defined in terms of the critical pressures and temperatures of the mixture components as

$$P'_{\text{cr},m} = \sum y_i P_{\text{cr},i} \quad \text{and} \quad T'_{\text{cr},m} = \sum y_i T_{\text{cr},i}$$

The compressibility factor of the mixture (Z_m) is then easily determined using these pseudo-critical point values.

13-28 The partial pressure of R-134a in atmospheric air to form a 100-ppm contaminant is to be determined.

Analysis Noting that volume fractions and mole fractions are equal, the molar fraction of R-134a in air is

$$y_{\text{R134a}} = \frac{100}{10^6} = 0.0001$$

The partial pressure of R-134a in air is then

$$P_{\text{R134a}} = y_{\text{R134a}} P_m = (0.0001)(100 \text{ kPa}) = \mathbf{0.01 \text{ kPa}}$$

13-29 A tank contains a mixture of two gases of known masses at a specified pressure and temperature. The mixture is now heated to a specified temperature. The volume of the tank and the final pressure of the mixture are to be determined.

Assumptions Under specified conditions both Ar and N₂ can be treated as ideal gases, and the mixture as an ideal gas mixture.

Analysis The total number of moles is

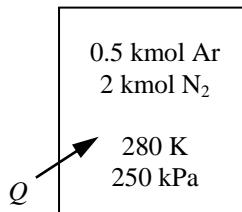

$$N_m = N_{\text{Ar}} + N_{\text{N}_2} = 0.5 \text{ kmol} + 2 \text{ kmol} = 2.5 \text{ kmol}$$

and

$$\mathcal{V}_m = \frac{N_m R_u T_m}{P_m} = \frac{(2.5 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(280 \text{ K})}{250 \text{ kPa}} = \mathbf{23.3 \text{ m}^3}$$

Also,

$$\frac{P_2 \mathcal{V}_2}{T_2} = \frac{P_1 \mathcal{V}_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{400 \text{ K}}{280 \text{ K}} (250 \text{ kPa}) = \mathbf{357.1 \text{ kPa}}$$

13-30 The volume fractions of components of a gas mixture are given. The mass fractions and apparent molecular weight of the mixture are to be determined.

Properties The molar masses of H₂, He, and N₂ are 2.0, 4.0, and 28.0 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned}m_{\text{H}_2} &= N_{\text{H}_2} M_{\text{H}_2} = (30 \text{ kmol})(2 \text{ kg/kmol}) = 60 \text{ kg} \\m_{\text{He}} &= N_{\text{He}} M_{\text{He}} = (40 \text{ kmol})(4 \text{ kg/kmol}) = 160 \text{ kg} \\m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (30 \text{ kmol})(28 \text{ kg/kmol}) = 840 \text{ kg}\end{aligned}$$

The total mass is

$$m_m = m_{\text{H}_2} + m_{\text{He}} + m_{\text{N}_2} = 60 + 160 + 840 = 1060 \text{ kg}$$

Then the mass fractions are

30% H₂
40% He
30% N₂
(by volume)

$$\text{mf}_{\text{H}_2} = \frac{m_{\text{H}_2}}{m_m} = \frac{60 \text{ kg}}{1060 \text{ kg}} = \mathbf{0.05660}$$

$$\text{mf}_{\text{He}} = \frac{m_{\text{He}}}{m_m} = \frac{160 \text{ kg}}{1060 \text{ kg}} = \mathbf{0.1509}$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{840 \text{ kg}}{1060 \text{ kg}} = \mathbf{0.7925}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1060 \text{ kg}}{100 \text{ kmol}} = \mathbf{10.60 \text{ kg/kmol}}$$

13-31 The partial pressures of a gas mixture are given. The mole fractions, the mass fractions, the mixture molar mass, the apparent gas constant, the constant-volume specific heat, and the specific heat ratio are to be determined.

Properties The molar masses of CO₂, O₂ and N₂ are 44.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at 300 K are 0.657, 0.658, and 0.743 kJ/kg·K, respectively (Table A-2a).

Analysis The total pressure is

$$P_{\text{total}} = P_{\text{CO}_2} + P_{\text{O}_2} + P_{\text{N}_2} = 12.5 + 37.5 + 50 = 100 \text{ kPa}$$

The volume fractions are equal to the pressure fractions. Then,

$$y_{\text{CO}_2} = \frac{P_{\text{CO}_2}}{P_{\text{total}}} = \frac{12.5}{100} = \mathbf{0.125}$$

$$y_{\text{O}_2} = \frac{P_{\text{O}_2}}{P_{\text{total}}} = \frac{37.5}{100} = \mathbf{0.375}$$

$$y_{\text{N}_2} = \frac{P_{\text{N}_2}}{P_{\text{total}}} = \frac{50}{100} = \mathbf{0.50}$$

Partial
pressures
CO₂, 12.5 kPa
O₂, 37.5 kPa
N₂, 50 kPa

We consider 100 kmol of this mixture. Then the mass of each component are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (12.5 \text{ kmol})(44 \text{ kg/kmol}) = 550 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (37.5 \text{ kmol})(32 \text{ kg/kmol}) = 1200 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (50 \text{ kmol})(28 \text{ kg/kmol}) = 1400 \text{ kg}$$

The total mass is

$$m_m = m_{\text{N}_2} + m_{\text{O}_2} + m_{\text{Ar}} = 550 + 1200 + 1400 = 3150 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_m} = \frac{550 \text{ kg}}{3150 \text{ kg}} = \mathbf{0.1746}$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{1200 \text{ kg}}{3150 \text{ kg}} = \mathbf{0.3810}$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{1400 \text{ kg}}{3150 \text{ kg}} = \mathbf{0.4444}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{3150 \text{ kg}}{100 \text{ kmol}} = \mathbf{31.50 \text{ kg/kmol}}$$

The constant-volume specific heat of the mixture is determined from

$$\begin{aligned} c_v &= \text{mf}_{\text{CO}_2} c_{v,\text{CO}_2} + \text{mf}_{\text{O}_2} c_{v,\text{O}_2} + \text{mf}_{\text{N}_2} c_{v,\text{N}_2} \\ &= 0.1746 \times 0.657 + 0.3810 \times 0.658 + 0.4444 \times 0.743 \\ &= \mathbf{0.6956 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{31.50 \text{ kg/kmol}} = \mathbf{0.2639 \text{ kJ/kg} \cdot \text{K}}$$

The constant-pressure specific heat of the mixture and the specific heat ratio are

$$c_p = c_v + R = 0.6956 + 0.2639 = \mathbf{0.9595 \text{ kJ/kg} \cdot \text{K}}$$

$$k = \frac{c_p}{c_v} = \frac{0.9595 \text{ kJ/kg} \cdot \text{K}}{0.6956 \text{ kJ/kg} \cdot \text{K}} = \mathbf{1.379}$$

13-32 The mole numbers of combustion gases are given. The partial pressure of water vapor is to be determined.

Analysis The total mole of the mixture and the mole fraction of water vapor are

$$N_{\text{total}} = 0.75 + 1.66 + 5.65 = 8.06 \text{ kmol}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{1.66}{8.06} = 0.2060$$

Noting that molar fraction is equal to pressure fraction, the partial pressure of water vapor is

$$P_{\text{H}_2\text{O}} = y_{\text{H}_2\text{O}} P_{\text{total}} (0.2060)(101.3 \text{ kPa}) = \mathbf{20.86 \text{ kPa}}$$

13-33 An additional 5% of oxygen is mixed with standard atmospheric air. The molecular weight of this mixture is to be determined.

Properties The molar masses of N₂ and O₂ are 28.0 and 32.0 kg/kmol, respectively (Table A-1).

Analysis Standard air is taken as 79% nitrogen and 21% oxygen by mole. That is,

$$y_{\text{O}_2} = 0.21$$

$$y_{\text{N}_2} = 0.79$$

Adding another 0.05 moles of O₂ to 1 kmol of standard air gives

$$y_{\text{O}_2} = \frac{0.26}{1.05} = 0.2476$$

$$y_{\text{N}_2} = \frac{0.79}{1.05} = 0.7524$$

Then,

$$M_m = y_{\text{O}_2} M_{\text{O}_2} + y_{\text{N}_2} M_{\text{N}_2} = 0.2476 \times 32 + 0.7524 \times 28 = \mathbf{28.99 \text{ kg/kmol}}$$

13-34 The masses, temperatures, and pressures of two gases contained in two tanks connected to each other are given. The valve connecting the tanks is opened and the final temperature is measured. The volume of each tank and the final pressure are to be determined.

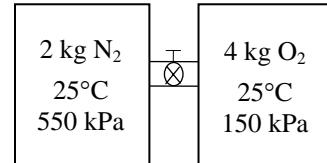

Assumptions Under specified conditions both N₂ and O₂ can be treated as ideal gases, and the mixture as an ideal gas mixture

Properties The molar masses of N₂ and O₂ are 28.0 and 32.0 kg/kmol, respectively. The gas constants of N₂ and O₂ are 0.2968 and 0.2598 kPa·m³/kg·K, respectively (Table A-1).

Analysis The volumes of the tanks are

$$V_{N_2} = \left(\frac{mRT}{P} \right)_{N_2} = \frac{(2 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{550 \text{ kPa}} = 0.322 \text{ m}^3$$

$$V_{O_2} = \left(\frac{mRT}{P} \right)_{O_2} = \frac{(4 \text{ kg})(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{150 \text{ kPa}} = 2.065 \text{ m}^3$$

$$V_{\text{total}} = V_{N_2} + V_{O_2} = 0.322 \text{ m}^3 + 2.065 \text{ m}^3 = 2.386 \text{ m}^3$$

Also,

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{2 \text{ kg}}{28 \text{ kg/kmol}} = 0.07143 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{4 \text{ kg}}{32 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

$$N_m = N_{N_2} + N_{O_2} = 0.07143 \text{ kmol} + 0.125 \text{ kmol} = 0.1964 \text{ kmol}$$

Thus,

$$P_m = \left(\frac{NR_u T}{V} \right)_m = \frac{(0.1964 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(298 \text{ K})}{2.386 \text{ m}^3} = 204 \text{ kPa}$$

13-35 The masses of components of a gas mixture are given. The apparent molecular weight of this mixture, the volume it occupies, the partial volume of the oxygen, and the partial pressure of the helium are to be determined.

Properties The molar masses of O₂, CO₂, and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1).

Analysis The total mass of the mixture is

$$m_m = m_{O_2} + m_{CO_2} + m_{He} = 0.1 + 1 + 0.5 = 1.6 \text{ kg}$$

The mole numbers of each component are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{0.1 \text{ kg}}{32 \text{ kg/kmol}} = 0.003125 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.02273 \text{ kmol}$$

$$N_{He} = \frac{m_{He}}{M_{He}} = \frac{0.5 \text{ kg}}{4 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

0.1 kg O₂
1 kg CO₂
0.5 kg He

The mole number of the mixture is

$$N_m = N_{O_2} + N_{CO_2} + N_{He} = 0.003125 + 0.02273 + 0.125 = 0.15086 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{1.6 \text{ kg}}{0.15086 \text{ kmol}} = \mathbf{10.61 \text{ kg/kmol}}$$

The volume of this ideal gas mixture is

$$V_m = \frac{N_m R_u T}{P} = \frac{(0.1509 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(300 \text{ K})}{100 \text{ kPa}} = \mathbf{3.764 \text{ m}^3}$$

The partial volume of oxygen in the mixture is

$$V_{O_2} = y_{O_2} V_m = \frac{N_{O_2}}{N_m} V_m = \frac{0.003125 \text{ kmol}}{0.1509 \text{ kmol}} (3.764 \text{ m}^3) = \mathbf{0.07795 \text{ m}^3}$$

The partial pressure of helium in the mixture is

$$P_{He} = y_{He} P_m = \frac{N_{He}}{N_m} P_m = \frac{0.125 \text{ kmol}}{0.1509 \text{ kmol}} (100 \text{ kPa}) = \mathbf{82.84 \text{ kPa}}$$

13-36 The mass fractions of components of a gas mixture are given. The volume occupied by 100 kg of this mixture is to be determined.

Properties The molar masses of CH₄, C₃H₈, and C₄H₁₀ are 16.0, 44.0, and 58.0 kg/kmol, respectively (Table A-1).

Analysis The mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_3\text{H}_8} = \frac{m_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.5682 \text{ kmol}$$

$$N_{\text{C}_4\text{H}_{10}} = \frac{m_{\text{C}_4\text{H}_{10}}}{M_{\text{C}_4\text{H}_{10}}} = \frac{15 \text{ kg}}{58 \text{ kg/kmol}} = 0.2586 \text{ kmol}$$

60% CH₄
25% C₃H₈
15% C₄H₁₀
(by mass)

The mole number of the mixture is

$$N_m = N_{\text{CH}_4} + N_{\text{C}_3\text{H}_8} + N_{\text{C}_4\text{H}_{10}} = 3.75 + 0.5682 + 0.2586 = 4.5768 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{4.5768 \text{ kmol}} = 21.85 \text{ kg/kmol}$$

Then the volume of this ideal gas mixture is

$$V_m = \frac{N_m R_u T}{P} = \frac{(4.5768 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(310 \text{ K})}{3000 \text{ kPa}} = \mathbf{3.93 \text{ m}^3}$$

13-37E The mass fractions of components of a gas mixture are given. The mass of 7 ft³ of this mixture and the partial volumes of the components are to be determined.

Properties The molar masses of N₂, O₂, and He are 28.0, 32.0, and 4.0 lbm/lbmol, respectively (Table A-1E).

Analysis We consider 100 lbm of this mixture for calculating the molar mass of the mixture. The mole numbers of each component are

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{45 \text{ lbm}}{28 \text{ lbm/lbmol}} = 1.607 \text{ lbmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{35 \text{ lbm}}{32 \text{ lbm/lbmol}} = 1.094 \text{ lbmol}$$

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{20 \text{ lbm}}{4 \text{ lbm/lbmol}} = 5 \text{ lbmol}$$

7 ft ³
45% N ₂
35% O ₂
20% He
(by mass)

The mole number of the mixture is

$$N_m = N_{\text{N}_2} + N_{\text{O}_2} + N_{\text{He}} = 1.607 + 1.094 + 5 = 7.701 \text{ lbmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{7.701 \text{ lbmol}} = 12.99 \text{ lbm/lbmol}$$

Then the mass of this ideal gas mixture is

$$m = \frac{P M_m}{R_u T} = \frac{(300 \text{ psia})(7 \text{ ft}^3)(12.99 \text{ lbm/lbmol})}{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(520 \text{ R})} = \mathbf{4.887 \text{ lbm}}$$

The mole fractions are

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{1.607 \text{ lbmol}}{7.701 \text{ lbmol}} = 0.2087$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{1.094 \text{ lbmol}}{7.701 \text{ lbmol}} = 0.142$$

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_m} = \frac{5 \text{ lbmol}}{7.701 \text{ lbmol}} = 0.6493$$

Noting that volume fractions are equal to mole fractions, the partial volumes are determined from

$$\nu_{\text{N}_2} = y_{\text{N}_2} \nu_m = (0.2087)(7 \text{ ft}^3) = \mathbf{1.461 \text{ ft}^3}$$

$$\nu_{\text{O}_2} = y_{\text{O}_2} \nu_m = (0.142)(7 \text{ ft}^3) = \mathbf{0.994 \text{ ft}^3}$$

$$\nu_{\text{He}} = y_{\text{He}} \nu_m = (0.6493)(7 \text{ ft}^3) = \mathbf{4.545 \text{ ft}^3}$$

13-38 The mass fractions of components of a gas mixture are given. The partial pressure of ethane is to be determined.

Properties The molar masses of CH₄ and C₂H₆ are 16.0 and 30.0 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{70 \text{ kg}}{16 \text{ kg/kmol}} = 4.375 \text{ kmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{30 \text{ kg}}{30 \text{ kg/kmol}} = 1.0 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6} = 4.375 + 1.0 = 5.375 \text{ kmol}$$

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.375 \text{ kmol}}{5.375 \text{ kmol}} = 0.8139$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{1.0 \text{ kmol}}{5.375 \text{ kmol}} = 0.1861$$

70% CH₄
 30% C₂H₆
 (by mass)
 100 m³
 130 kPa, 25°C

The final pressure of ethane in the final mixture is

$$P_{\text{C}_2\text{H}_6} = y_{\text{C}_2\text{H}_6} P_m = (0.1861)(130 \text{ kPa}) = \mathbf{24.19 \text{ kPa}}$$

13-39 A container contains a mixture of two fluids. The volume of the container and the total weight of its contents are to be determined.

Assumptions The volume of the mixture is the sum of the volumes of the two constituents.

Properties The specific volumes of the two fluids are given to be 0.001 m³/kg and 0.008 m³/kg.

Analysis The volumes of the two fluids are given by

$$\mathcal{V}_A = m_A v_A = (1 \text{ kg})(0.001 \text{ m}^3/\text{kg}) = 0.001 \text{ m}^3$$

$$\mathcal{V}_B = m_B v_B = (2 \text{ kg})(0.008 \text{ m}^3/\text{kg}) = 0.016 \text{ m}^3$$

The volume of the container is then

$$\mathcal{V} = \mathcal{V}_A + \mathcal{V}_B = 0.001 + 0.016 = \mathbf{0.017 \text{ m}^3}$$

1 kg fluid A
 2 kg fluid B

The total mass is

$$m = m_A + m_B = 1 + 2 = 3 \text{ kg}$$

and the weight of this mass will be

$$W = mg = (3 \text{ kg})(9.6 \text{ m/s}^2) = 28.8 \text{ kg} \cdot \text{m/s}^2 = \mathbf{28.8 \text{ N}}$$

13-40E A mixture consists of liquid water and another fluid. The specific weight of this mixture is to be determined.

Properties The densities of water and the fluid are given to be 62.4 lbm/ft³ and 50.0 lbm/ft³, respectively.

Analysis We consider 1 ft³ of this mixture. The volume of the water in the mixture is 0.7 ft³ which has a mass of

$$m_w = \rho_w V_w = (62.4 \text{ lbm/ft}^3)(0.7 \text{ ft}^3) = 43.68 \text{ lbm}$$

The weight of this water is

$$W_w = m_w g = (43.68 \text{ lbm})(31.9 \text{ ft/s}^2) \left(\frac{1 \text{ lbf}}{32.174 \text{ lbm} \cdot \text{ft/s}^2} \right) = 43.31 \text{ lbf}$$

Similarly, the volume of the second fluid is 0.3 ft³, and the mass of this fluid is

$$m_f = \rho_f V_f = (50 \text{ lbm/ft}^3)(0.3 \text{ ft}^3) = 15 \text{ lbm}$$

The weight of the fluid is

$$W_f = m_f g = (15 \text{ lbm})(31.9 \text{ ft/s}^2) \left(\frac{1 \text{ lbf}}{32.174 \text{ lbm} \cdot \text{ft/s}^2} \right) = 14.87 \text{ lbf}$$

The specific weight of this mixture is then

$$\gamma = \frac{W_w + W_f}{V_w + V_f} = \frac{(43.31 + 14.87) \text{ lbf}}{(0.7 + 0.3) \text{ ft}^3} = \mathbf{58.2 \text{ lbf/ft}^3}$$

0.7 ft³ water
0.3 ft³ fluid

13-41 The mole fractions of components of a gas mixture are given. The mass flow rate of the mixture is to be determined.

Properties The molar masses of air and CH₄ are 28.97 and 16.0 kg/kmol, respectively (Table A-1).

Analysis The molar fraction of air is

$$y_{\text{air}} = 1 - y_{\text{CH}_4} = 1 - 0.15 = 0.85$$

The molar mass of the mixture is determined from

$$\begin{aligned} M_m &= y_{\text{CH}_4} M_{\text{CH}_4} + y_{\text{air}} M_{\text{air}} \\ &= 0.15 \times 16 + 0.85 \times 28.97 \\ &= 27.02 \text{ kg/kmol} \end{aligned}$$

15% CH₄
85% air
(by mole)

Given the engine displacement and speed and assuming that this is a 4-stroke engine (2 revolutions per cycle), the volume flow rate is determined from

$$\dot{V} = \frac{\dot{n} V_d}{2} = \frac{(3000 \text{ rev/min})(0.005 \text{ m}^3)}{2 \text{ rev/cycle}} = 7.5 \text{ m}^3/\text{min}$$

The specific volume of the mixture is

$$\nu = \frac{R_u T}{M_m P} = \frac{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})}{(27.02 \text{ kg/kmol})(80 \text{ kPa})} = 1.127 \text{ m}^3/\text{kg}$$

Hence the mass flow rate is

$$\dot{m} = \frac{\dot{V}}{\nu} = \frac{7.5 \text{ m}^3/\text{min}}{1.127 \text{ m}^3/\text{kg}} = \mathbf{6.65 \text{ kg/min}}$$

13-42E The volumetric fractions of components of a natural gas mixture are given. The mass and volume flow rates of the mixture are to be determined.

Properties The molar masses of CH₄ and C₂H₆ are 16.0 and 30.0 lbm/lbmol, respectively (Table A-1E).

Analysis The molar mass of the mixture is determined from

$$M_m = y_{\text{CH}_4} M_{\text{CH}_4} + y_{\text{C}_2\text{H}_6} M_{\text{C}_2\text{H}_6} = 0.95 \times 16 + 0.05 \times 30 = 16.70 \text{ lbm/lbmol}$$

The specific volume of the mixture is

$$\nu = \frac{R_u T}{M_m P} = \frac{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbfmol} \cdot \text{R})(520 \text{ R})}{(16.70 \text{ lbm/lbmol})(100 \text{ psia})} = 3.341 \text{ ft}^3/\text{lbf}$$

	→	95% CH ₄
		5% C ₂ H ₆
		(by volume)

The volume flow rate is

$$\dot{V} = AV = \frac{\pi D^2}{4} V = \frac{\pi (36/12 \text{ ft})^2}{4} (10 \text{ ft/s}) = \mathbf{70.69 \text{ ft}^3/\text{s}}$$

and the mass flow rate is

$$\dot{m} = \frac{\dot{V}}{\nu} = \frac{70.69 \text{ ft}^3/\text{s}}{3.341 \text{ ft}^3/\text{lbf}} = \mathbf{21.16 \text{ lbm/s}}$$

13-43 The mole numbers, temperatures, and pressures of two gases forming a mixture are given. The final temperature is also given. The pressure of the mixture is to be determined using two methods.

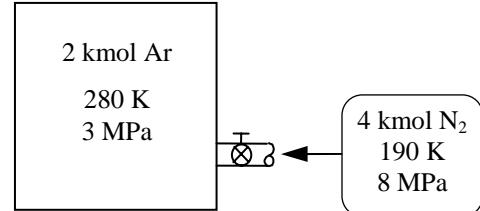

Analysis (a) Under specified conditions both Ar and N₂ will considerably deviate from the ideal gas behavior. Treating the mixture as an ideal gas,

$$\text{Initial state: } P_1 V_1 = N_1 R_u T_1 \quad \left. \begin{array}{l} \\ \end{array} \right\} P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(6)(230 \text{ K})}{(2)(280 \text{ K})} (3 \text{ MPa}) = 7.39 \text{ MPa}$$

$$\text{Final state: } P_2 V_2 = N_2 R_u T_2 \quad \left. \begin{array}{l} \\ \end{array} \right\}$$

(b) Initially,

$$\left. \begin{array}{l} T_R = \frac{T_1}{T_{\text{cr,Ar}}} = \frac{280 \text{ K}}{151.0 \text{ K}} = 1.854 \\ P_R = \frac{P_1}{P_{\text{cr,Ar}}} = \frac{3 \text{ MPa}}{4.86 \text{ MPa}} = 0.6173 \end{array} \right\} Z_{\text{Ar}} = 0.985 \text{ (Fig. A-15 or EES)}$$

Then the volume of the tank is

$$V = \frac{ZN_{\text{Ar}}R_uT}{P} = \frac{(0.985)(2 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(280 \text{ K})}{3000 \text{ kPa}} = 1.529 \text{ m}^3$$

After mixing,

$$\left. \begin{array}{l} T_{R,\text{Ar}} = \frac{T_m}{T_{\text{cr,Ar}}} = \frac{230 \text{ K}}{151.0 \text{ K}} = 1.523 \\ \text{Ar: } \nu_{R,\text{Ar}} = \frac{\nu_{\text{Ar}}}{R_u T_{\text{cr,Ar}} / P_{\text{cr,Ar}}} = \frac{\nu_m / N_{\text{Ar}}}{R_u T_{\text{cr,Ar}} / P_{\text{cr,Ar}}} \\ = \frac{(1.529 \text{ m}^3)/(2 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(151.0 \text{ K})/(4860 \text{ kPa})} = 2.96 \end{array} \right\} P_R = 0.496 \text{ (Fig. A-15 or EES)}$$

$$\left. \begin{array}{l} T_{R,\text{N}_2} = \frac{T_m}{T_{\text{cr,N}_2}} = \frac{230 \text{ K}}{126.2 \text{ K}} = 1.823 \\ \text{N}_2: \nu_{R,\text{N}_2} = \frac{\nu_{\text{N}_2}}{R_u T_{\text{cr,N}_2} / P_{\text{cr,N}_2}} = \frac{\nu_m / N_{\text{N}_2}}{R_u T_{\text{cr,N}_2} / P_{\text{cr,N}_2}} \\ = \frac{(1.529 \text{ m}^3)/(4 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(126.2 \text{ K})/(3390 \text{ kPa})} = 1.235 \end{array} \right\} P_R = 1.43 \text{ (Fig. A-15 or EES)}$$

Thus,

$$P_{\text{Ar}} = (P_R P_{\text{cr}})_{\text{Ar}} = (0.496)(4.86 \text{ MPa}) = 2.41 \text{ MPa}$$

$$P_{\text{N}_2} = (P_R P_{\text{cr}})_{\text{N}_2} = (1.43)(3.39 \text{ MPa}) = 4.85 \text{ MPa}$$

and

$$P_m = P_{\text{Ar}} + P_{\text{N}_2} = 2.41 \text{ MPa} + 4.85 \text{ MPa} = 7.26 \text{ MPa}$$

13-44 Problem 13-43 is reconsidered. The effect of the moles of nitrogen supplied to the tank on the final pressure of the mixture is to be studied using the ideal-gas equation of state and the compressibility chart with Dalton's law.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data"

```
R_u = 8.314 [kJ/kmol-K] "universal Gas Constant"

13-45E The mass fractions of gases forming a mixture at a specified pressure and temperature are given. The mass of the gas mixture is to be determined using four methods.

Properties The molar masses of CH₄ and C₂H₆ are 16.0 and 30.0 lbm/lbmol, respectively (Table A-1E).

Analysis (a) We consider 100 lbm of this mixture. Then the mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ lbm}}{16 \text{ lbm/lbmol}} = 4.6875 \text{ lbmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{25 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.8333 \text{ lbmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 4.6875 + 0.8333 = 5.5208 \text{ lbmol}$$

75% CH₄
25% C₂H₆
(by mass)
2000 psia
300°F

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.6875 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.8491$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{0.8333 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.1509$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m}{N_m} = \frac{100 \text{ lbm}}{5.5208 \text{ lbmol}} = 18.11 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{10.73 \text{ psia} \cdot \text{ft}^3 / \text{lbmol} \cdot \text{R}}{18.11 \text{ lbm/lbmol}} = 0.5925 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R}$$

The mass of this mixture in a 1 million ft³ tank is

$$m = \frac{PV}{RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.5925 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(760 \text{ R})} = 4.441 \times 10^6 \text{ lbm}$$

(b) To use the Amagat's law for this real gas mixture, we first need the compressibility factor of each component at the mixture temperature and pressure. The compressibility factors are obtained using Fig. A-15 to be

$$\left. \begin{aligned} T_{R,\text{CH}_4} &= \frac{T_m}{T_{\text{cr},\text{CH}_4}} = \frac{760 \text{ R}}{343.9 \text{ R}} = 2.210 \\ P_{R,\text{CH}_4} &= \frac{P_m}{P_{\text{cr},\text{CH}_4}} = \frac{2000 \text{ psia}}{673 \text{ psia}} = 2.972 \end{aligned} \right\} Z_{\text{CH}_4} = 0.98 \quad \left. \begin{aligned} T_{R,\text{C}_2\text{H}_6} &= \frac{760 \text{ R}}{549.8 \text{ R}} = 1.382 \\ P_{R,\text{C}_2\text{H}_6} &= \frac{1500 \text{ psia}}{708 \text{ psia}} = 2.119 \end{aligned} \right\} Z_{\text{C}_2\text{H}_6} = 0.77$$

Then,

$$Z_m = \sum y_i Z_i = y_{\text{CH}_4} Z_{\text{CH}_4} + y_{\text{C}_2\text{H}_6} Z_{\text{C}_2\text{H}_6} = (0.8491)(0.98) + (0.1509)(0.77) = 0.9483$$

$$m = \frac{PV}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.9483)(0.5925 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(760 \text{ R})} = 4.684 \times 10^6 \text{ lbm}$$

(c) To use Dalton's law with compressibility factors: (Fig. A-15)

$$\left. \begin{aligned} T_{R,\text{CH}_4} &= 2.210 \\ V_{R,\text{CH}_4} &= \frac{V_m / m_{\text{CH}_4}}{R_{\text{CH}_4} T_{\text{cr},\text{CH}_4} / P_{\text{cr},\text{CH}_4}} = \frac{(1 \times 10^6 \text{ ft}^3) / (4.441 \times 10^6 \times 0.75 \text{ lbm})}{(0.6688 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(343.9 \text{ R}) / (673 \text{ psia})} = 0.8782 \end{aligned} \right\} Z_{\text{CH}_4} = 0.98$$

$$\left. \begin{aligned} T_{R,C2H_6} &= 1.382 \\ \frac{V_m/m_{C2H_6}}{RT_{cr,C2H_6}/P_{cr,C2H_6}} &= \frac{(1 \times 10^6 \text{ ft}^3)/(4.441 \times 10^6 \times 0.25 \text{ lbm})}{(0.3574 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(549.8 \text{ R})/(708 \text{ psia})} = 3.244 \end{aligned} \right\} Z_{CH_4} = 0.92$$

Note that we used $m = 4.441 \times 10^6 \times 0.25 \text{ lbm}$ in above calculations, the value obtained by ideal gas behavior. The solution normally requires iteration until the assumed and calculated mass values match. The mass of the component gas is obtained by multiplying the mass of the mixture by its mass fraction. Then,

$$Z_m = \sum y_i Z_i = y_{CH_4} Z_{CH_4} + y_{C2H_6} Z_{C2H_6} = (0.8491)(0.98) + (0.1509)(0.92) = 0.9709$$

$$m = \frac{PV}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.9709)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = 4.575 \times 10^6 \text{ lbm}$$

This mass is sufficiently close to the assumed mass value of $4.441 \times 10^6 \times 0.25 \text{ lbm}$. Therefore, there is no need to repeat the calculations at this calculated mass.

(d) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$\begin{aligned} T'_{cr,m} &= \sum y_i T_{cr,i} = y_{CH_4} T_{cr,CH_4} + y_{C2H_6} T_{cr,C2H_6} \\ &= (0.8491)(343.9 \text{ R}) + (0.1509)(549.8 \text{ R}) = 375.0 \text{ R} \\ P'_{cr,m} &= \sum y_i P_{cr,i} = y_{CH_4} P_{cr,CH_4} + y_{C2H_6} P_{cr,C2H_6} \\ &= (0.8491)(673 \text{ psia}) + (0.1509)(708 \text{ psia}) = 678.3 \text{ psia} \end{aligned}$$

Then,

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{cr,m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_R &= \frac{P_m}{P'_{cr,m}} = \frac{2000 \text{ psia}}{678.3 \text{ psia}} = 2.949 \end{aligned} \right\} Z_m = 0.97 \quad (\text{Fig. A-15})$$

$$m = \frac{PV}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.97)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = 4.579 \times 10^6 \text{ lbm}$$

13-46 The volumetric analysis of a mixture of gases is given. The volumetric and mass flow rates are to be determined using three methods.

Properties The molar masses of O₂, N₂, CO₂, and CH₄ are 32.0, 28.0, 44.0, and 16.0 kg/kmol, respectively (Table A-1).

Analysis (a) We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned}m_{\text{O}_2} &= N_{\text{O}_2} M_{\text{O}_2} = (30 \text{ kmol})(32 \text{ kg/kmol}) = 960 \text{ kg} \\m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (40 \text{ kmol})(28 \text{ kg/kmol}) = 1120 \text{ kg} \\m_{\text{CO}_2} &= N_{\text{CO}_2} M_{\text{CO}_2} = (10 \text{ kmol})(44 \text{ kg/kmol}) = 440 \text{ kg} \\m_{\text{CH}_4} &= N_{\text{CH}_4} M_{\text{CH}_4} = (20 \text{ kmol})(16 \text{ kg/kmol}) = 320 \text{ kg}\end{aligned}$$

The total mass is

$$\begin{aligned}m_m &= m_{\text{O}_2} + m_{\text{N}_2} + m_{\text{CO}_2} + m_{\text{CH}_4} \\&= 960 + 1120 + 440 + 320 = 2840 \text{ kg}\end{aligned}$$

30% O₂
40% N₂
10% CO₂
20% CH₄
(by volume)

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2840 \text{ kg}}{100 \text{ kmol}} = 28.40 \text{ kg/kmol}$$

Mixture
→ 8 MPa, 15°C

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.40 \text{ kg/kmol}} = 0.2927 \text{ kJ/kg} \cdot \text{K}$$

The specific volume of the mixture is

$$v = \frac{RT}{P} = \frac{(0.2927 \text{ kJ/kg} \cdot \text{K})(288 \text{ K})}{8000 \text{ kPa}} = 0.01054 \text{ m}^3/\text{kg}$$

The volume flow rate is

$$\dot{V} = AV = \frac{\pi D^2}{4} V = \frac{\pi(0.02 \text{ m})^2}{4} (3 \text{ m/s}) = \mathbf{0.0009425 \text{ m}^3/\text{s}}$$

and the mass flow rate is

$$\dot{m} = \frac{\dot{V}}{v} = \frac{0.0009425 \text{ m}^3/\text{s}}{0.01054 \text{ m}^3/\text{kg}} = \mathbf{0.08942 \text{ kg/s}}$$

(b) To use the Amagat's law for this real gas mixture, we first need the mole fractions and the Z of each component at the mixture temperature and pressure. The compressibility factors are obtained using Fig. A-15 to be

$$\left. \begin{array}{l} T_{R,\text{O}_2} = \frac{T_m}{T_{\text{cr},\text{O}_2}} = \frac{288 \text{ K}}{154.8 \text{ K}} = 1.860 \\ P_{R,\text{O}_2} = \frac{P_m}{P_{\text{cr},\text{O}_2}} = \frac{8 \text{ MPa}}{5.08 \text{ MPa}} = 1.575 \end{array} \right\} Z_{\text{O}_2} = 0.95 \quad \left. \begin{array}{l} T_{R,\text{N}_2} = \frac{288 \text{ K}}{126.2 \text{ K}} = 2.282 \\ P_{R,\text{N}_2} = \frac{8 \text{ MPa}}{3.39 \text{ MPa}} = 2.360 \end{array} \right\} Z_{\text{N}_2} = 0.99$$

$$\left. \begin{array}{l} T_{R,\text{CO}_2} = \frac{288 \text{ K}}{304.2 \text{ K}} = 0.947 \\ P_{R,\text{CO}_2} = \frac{8 \text{ MPa}}{7.39 \text{ MPa}} = 1.083 \end{array} \right\} Z_{\text{CO}_2} = 0.199 \quad \left. \begin{array}{l} T_{R,\text{CH}_4} = \frac{288 \text{ K}}{191.1 \text{ K}} = 1.507 \\ P_{R,\text{CH}_4} = \frac{8 \text{ MPa}}{4.64 \text{ MPa}} = 1.724 \end{array} \right\} Z_{\text{CH}_4} = 0.85$$

and

$$\begin{aligned}Z_m &= \sum y_i Z_i = y_{\text{O}_2} Z_{\text{O}_2} + y_{\text{N}_2} Z_{\text{N}_2} + y_{\text{CO}_2} Z_{\text{CO}_2} + y_{\text{CH}_4} Z_{\text{CH}_4} \\&= (0.30)(0.95) + (0.40)(0.99) + (0.10)(0.199) + (0.20)(0.85) = 0.8709\end{aligned}$$

Then,

$$\nu = \frac{Z_m RT}{P} = \frac{(0.8709)(0.2927 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(288 \text{ K})}{8000 \text{ kPa}} = 0.009178 \text{ m}^3/\text{kg}$$

$$\dot{V} = 0.0009425 \text{ m}^3/\text{s}$$

$$\dot{m} = \frac{\dot{V}}{\nu} = \frac{0.0009425 \text{ m}^3/\text{s}}{0.009178 \text{ m}^3/\text{kg}} = 0.10269 \text{ kg/s}$$

(c) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of mixture gases.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{O}_2} T_{\text{cr,O}_2} + y_{\text{N}_2} T_{\text{cr,N}_2} + y_{\text{CO}_2} T_{\text{cr,CO}_2} + y_{\text{CH}_4} T_{\text{cr,CH}_4} \\ &= (0.30)(154.8 \text{ K}) + (0.40)(126.2 \text{ K}) + (0.10)(304.2 \text{ K}) + (0.20)(191.1 \text{ K}) = 165.6 \text{ K} \\ P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{O}_2} P_{\text{cr,O}_2} + y_{\text{N}_2} P_{\text{cr,N}_2} + y_{\text{CO}_2} P_{\text{cr,CO}_2} + y_{\text{CH}_4} P_{\text{cr,CH}_4} \\ &= (0.30)(5.08 \text{ MPa}) + (0.40)(3.39 \text{ MPa}) + (0.10)(7.39 \text{ MPa}) + (0.20)(4.64 \text{ MPa}) = 4.547 \text{ MPa} \end{aligned}$$

and

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{\text{cr},m}} = \frac{288 \text{ K}}{165.6 \text{ K}} = 1.739 \\ P_R &= \frac{P_m}{P'_{\text{cr},m}} = \frac{8 \text{ MPa}}{4.547 \text{ MPa}} = 1.759 \end{aligned} \right\} Z_m = 0.92 \quad (\text{Fig. A-15})$$

Then,

$$\nu = \frac{Z_m RT}{P} = \frac{(0.92)(0.2927 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(288 \text{ K})}{8000 \text{ kPa}} = 0.009694 \text{ m}^3/\text{kg}$$

$$\dot{V} = 0.0009425 \text{ m}^3/\text{s}$$

$$\dot{m} = \frac{\dot{V}}{\nu} = \frac{0.0009425 \text{ m}^3/\text{s}}{0.009694 \text{ m}^3/\text{kg}} = 0.009723 \text{ kg/s}$$

Properties of Gas Mixtures

13-47C Yes. Yes (extensive property).

13-48C No (intensive property).

13-49C The answers are the same for entropy.

13-50C Yes. Yes (conservation of energy).

13-51C We have to use the partial pressure.

13-52C No, this is an approximate approach. It assumes a component behaves as if it existed alone at the mixture temperature and pressure (i.e., it disregards the influence of dissimilar molecules on each other.)

13-53 The volume fractions of components of a gas mixture are given. This mixture is heated while flowing through a tube at constant pressure. The heat transfer to the mixture per unit mass of the mixture is to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

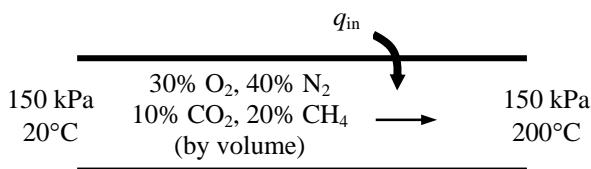

Properties The molar masses of O₂, N₂, CO₂, and CH₄ are 32.0, 28.0, 44.0, and 16.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 0.918, 1.039, 0.846, and 2.2537 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned}m_{\text{O}_2} &= N_{\text{O}_2} M_{\text{O}_2} = (30 \text{ kmol})(32 \text{ kg/kmol}) = 960 \text{ kg} \\m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (40 \text{ kmol})(28 \text{ kg/kmol}) = 1120 \text{ kg} \\m_{\text{CO}_2} &= N_{\text{CO}_2} M_{\text{CO}_2} = (10 \text{ kmol})(44 \text{ kg/kmol}) = 440 \text{ kg} \\m_{\text{CH}_4} &= N_{\text{CH}_4} M_{\text{CH}_4} = (20 \text{ kmol})(16 \text{ kg/kmol}) = 320 \text{ kg}\end{aligned}$$

The total mass is

$$\begin{aligned}m_m &= m_{\text{O}_2} + m_{\text{N}_2} + m_{\text{CO}_2} + m_{\text{CH}_4} \\&= 960 + 1120 + 440 + 320 \\&= 2840 \text{ kg}\end{aligned}$$

Then the mass fractions are

$$\begin{aligned}\text{mf}_{\text{O}_2} &= \frac{m_{\text{O}_2}}{m_m} = \frac{960 \text{ kg}}{2840 \text{ kg}} = 0.3380 \\\text{mf}_{\text{N}_2} &= \frac{m_{\text{N}_2}}{m_m} = \frac{1120 \text{ kg}}{2840 \text{ kg}} = 0.3944 \\\text{mf}_{\text{CO}_2} &= \frac{m_{\text{CO}_2}}{m_m} = \frac{440 \text{ kg}}{2840 \text{ kg}} = 0.1549 \\\text{mf}_{\text{CH}_4} &= \frac{m_{\text{CH}_4}}{m_m} = \frac{320 \text{ kg}}{2840 \text{ kg}} = 0.1127\end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned}c_p &= \text{mf}_{\text{O}_2} c_{p,\text{O}_2} + \text{mf}_{\text{N}_2} c_{p,\text{N}_2} + \text{mf}_{\text{CO}_2} c_{p,\text{CO}_2} + \text{mf}_{\text{CH}_4} c_{p,\text{CH}_4} \\&= 0.3380 \times 0.918 + 0.3944 \times 1.039 + 0.1549 \times 0.846 + 0.1127 \times 2.2537 \\&= 1.1051 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

An energy balance on the tube gives

$$q_{\text{in}} = c_p (T_2 - T_1) = (1.1051 \text{ kJ/kg} \cdot \text{K})(200 - 20) \text{ K} = \mathbf{199 \text{ kJ/kg}}$$

13-54E A mixture of helium and nitrogen is heated at constant pressure in a closed system. The work produced is to be determined.

Assumptions 1 Helium and nitrogen are ideal gases. 2 The process is reversible.

Properties The mole numbers of helium and nitrogen are 4.0 and 28.0 lbm/lbmol, respectively (Table A-1E).

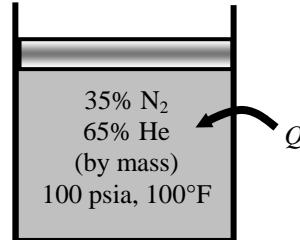

Analysis One lbm of this mixture consists of 0.35 lbm of nitrogen and 0.65 lbm of helium or $0.35 \text{ lbm}/(28.0 \text{ lbm/lbmol}) = 0.0125 \text{ lbmol}$ of nitrogen and $0.65 \text{ lbm}/(4.0 \text{ lbm/lbmol}) = 0.1625 \text{ lbmol}$ of helium. The total mole is $0.0125 + 0.1625 = 0.175 \text{ lbmol}$. The constituent mole fraction are then

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{total}}} = \frac{0.0125 \text{ lbmol}}{0.175 \text{ lbmol}} = 0.07143$$

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_{\text{total}}} = \frac{0.1625 \text{ lbmol}}{0.175 \text{ lbmol}} = 0.9286$$

The effective molecular weight of this mixture is

$$\begin{aligned} M &= y_{\text{N}_2} M_{\text{N}_2} + y_{\text{He}} M_{\text{He}} \\ &= (0.07143)(28) + (0.9286)(4) \\ &= 5.714 \text{ lbm/lbmol} \end{aligned}$$

The work done is determined from

$$\begin{aligned} w &= \int_1^2 P d\nu = P_2 \nu_2 - P_1 \nu_1 = R(T_2 - T_1) \\ &= \frac{R_u}{M} (T_2 - T_1) = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{5.714 \text{ lbm/lbmol}} (500 - 100) \text{R} = \mathbf{139.0 \text{ Btu/lbm}} \end{aligned}$$

13-55 The volume fractions of components of a gas mixture are given. This mixture is expanded isentropically to a specified pressure. The work produced per unit mass of the mixture is to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of H₂, He, and N₂ are 2.0, 4.0, and 28.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 14.307, 5.1926, and 1.039 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned}m_{\text{H}_2} &= N_{\text{H}_2} M_{\text{H}_2} = (30 \text{ kmol})(2 \text{ kg/kmol}) = 60 \text{ kg} \\m_{\text{He}} &= N_{\text{He}} M_{\text{He}} = (40 \text{ kmol})(4 \text{ kg/kmol}) = 160 \text{ kg} \\m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (30 \text{ kmol})(28 \text{ kg/kmol}) = 840 \text{ kg}\end{aligned}$$

The total mass is

$$m_m = m_{\text{H}_2} + m_{\text{He}} + m_{\text{N}_2} = 60 + 160 + 840 = 1060 \text{ kg}$$

30% H₂
40% He
30% N₂
(by volume)
5 MPa, 600°C

Then the mass fractions are

$$\begin{aligned}\text{mf}_{\text{H}_2} &= \frac{m_{\text{H}_2}}{m_m} = \frac{60 \text{ kg}}{1060 \text{ kg}} = 0.05660 \\\text{mf}_{\text{He}} &= \frac{m_{\text{He}}}{m_m} = \frac{160 \text{ kg}}{1060 \text{ kg}} = 0.1509 \\\text{mf}_{\text{N}_2} &= \frac{m_{\text{N}_2}}{m_m} = \frac{840 \text{ kg}}{1060 \text{ kg}} = 0.7925\end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1060 \text{ kg}}{100 \text{ kmol}} = 10.60 \text{ kg/kmol}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned}c_p &= \text{mf}_{\text{H}_2} c_{p,\text{H}_2} + \text{mf}_{\text{He}} c_{p,\text{He}} + \text{mf}_{\text{N}_2} c_{p,\text{N}_2} \\&= 0.05660 \times 14.307 + 0.1509 \times 5.1926 + 0.7925 \times 1.039 \\&= 2.417 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{10.60 \text{ kg/kmol}} = 0.7843 \text{ kJ/kg} \cdot \text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 2.417 - 0.7843 = 1.633 \text{ kJ/kg} \cdot \text{K}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{2.417}{1.633} = 1.480$$

The temperature at the end of the expansion is

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (873 \text{ K}) \left(\frac{200 \text{ kPa}}{5000 \text{ kPa}} \right)^{0.48/1.48} = 307 \text{ K}$$

An energy balance on the adiabatic expansion process gives

$$w_{\text{out}} = c_p (T_1 - T_2) = (2.417 \text{ kJ/kg} \cdot \text{K})(873 - 307) \text{ K} = \mathbf{1368 \text{ kJ/kg}}$$

13-56 The mass fractions of components of a gas mixture are given. This mixture is enclosed in a rigid, well-insulated vessel, and a paddle wheel in the vessel is turned until specified amount of work have been done on the mixture. The mixture's final pressure and temperature are to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N₂, He, CH₄, and C₂H₆ are 28.0, 4.0, 16.0, and 30.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 1.039, 5.1926, 2.2537, and 1.7662 kJ/kg·K, respectively (Table A-2a).

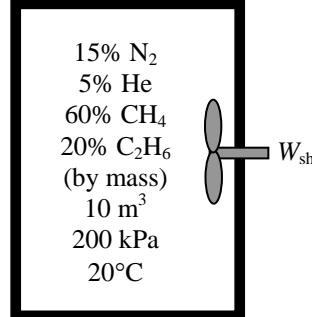

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{15 \text{ kg}}{28 \text{ kg/kmol}} = 0.5357 \text{ kmol}$$

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{5 \text{ kg}}{4 \text{ kg/kmol}} = 1.25 \text{ kmol}$$

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{20 \text{ kg}}{30 \text{ kg/kmol}} = 0.6667 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{\text{N}_2} + N_{\text{He}} + N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6} = 0.5357 + 1.25 + 3.75 + 0.6667 = 6.2024 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{6.2024 \text{ kmol}} = 16.12 \text{ kg/kmol}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{\text{N}_2}c_{p,\text{N}_2} + mf_{\text{He}}c_{p,\text{He}} + mf_{\text{CH}_4}c_{p,\text{CH}_4} + mf_{\text{C}_2\text{H}_6}c_{p,\text{C}_2\text{H}_6} \\ &= 0.15 \times 1.039 + 0.05 \times 5.1926 + 0.60 \times 2.2537 + 0.20 \times 1.7662 \\ &= 2.121 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{16.12 \text{ kg/kmol}} = 0.5158 \text{ kJ/kg} \cdot \text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 2.121 - 0.5158 = 1.605 \text{ kJ/kg} \cdot \text{K}$$

The mass in the container is

$$m_m = \frac{P_1 V_m}{RT_1} = \frac{(200 \text{ kPa})(10 \text{ m}^3)}{(0.5158 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 13.23 \text{ kg}$$

An energy balance on the system gives

$$W_{\text{sh,in}} = m_m c_v (T_2 - T_1) \longrightarrow T_2 = T_1 + \frac{W_{\text{sh,in}}}{m_m c_v} = (293 \text{ K}) + \frac{100 \text{ kJ}}{(13.23 \text{ kg})(1.605 \text{ kJ/kg} \cdot \text{K})} = 297.7 \text{ K}$$

Since the volume remains constant and this is an ideal gas,

$$P_2 = P_1 \frac{T_2}{T_1} = (200 \text{ kPa}) \frac{297.7 \text{ K}}{293 \text{ K}} = 203.2 \text{ kPa}$$

13-57 Propane and air mixture is compressed isentropically in an internal combustion engine. The work input is to be determined.

Assumptions Under specified conditions propane and air can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of C₃H₈ and air are 44.0 and 28.97 kg/kmol, respectively (Table A-1).

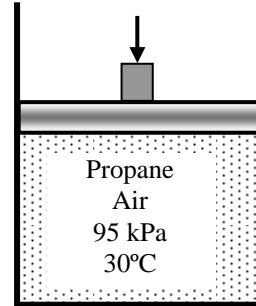

Analysis Given the air-fuel ratio, the mass fractions are determined to be

$$mf_{\text{air}} = \frac{\text{AF}}{\text{AF}+1} = \frac{16}{17} = 0.9412$$

$$mf_{\text{C}_3\text{H}_8} = \frac{1}{\text{AF}+1} = \frac{1}{17} = 0.05882$$

The molar mass of the mixture is determined to be

$$M_m = \frac{1}{\frac{mf_{\text{air}}}{M_{\text{air}}} + \frac{mf_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}}} = \frac{1}{\frac{0.9412}{28.97 \text{ kg/kmol}} + \frac{0.05882}{44.0 \text{ kg/kmol}}} = 29.56 \text{ kg/kmol}$$

The mole fractions are

$$y_{\text{air}} = mf_{\text{air}} \frac{M_m}{M_{\text{air}}} = (0.9412) \frac{29.56 \text{ kg/kmol}}{28.97 \text{ kg/kmol}} = 0.9606$$

$$y_{\text{C}_3\text{H}_8} = mf_{\text{C}_3\text{H}_8} \frac{M_m}{M_{\text{C}_3\text{H}_8}} = (0.05882) \frac{29.56 \text{ kg/kmol}}{44.0 \text{ kg/kmol}} = 0.03944$$

The final pressure is expressed from ideal gas relation to be

$$P_2 = P_1 r \frac{T_2}{T_1} = (95 \text{ kPa})(9.5) \frac{T_2}{(30 + 273.15) \text{ K}} = 2.977 T_2 \quad (1)$$

since the final temperature is not known. Using Dalton's law to find partial pressures, the entropies at the initial state are determined from EES to be:

$$T = 30^\circ\text{C}, P = (0.9606 \times 95) = 91.26 \text{ kPa} \longrightarrow s_{\text{air},1} = 5.7417 \text{ kJ/kg.K}$$

$$T = 30^\circ\text{C}, P = (0.03944 \times 95) = 3.75 \text{ kPa} \longrightarrow s_{\text{C}_3\text{H}_8,1} = 6.7697 \text{ kJ/kg.K}$$

The final state entropies cannot be determined at this point since the final pressure and temperature are not known. However, for an isentropic process, the entropy change is zero and the final temperature and the final pressure may be determined from

$$\Delta s_{\text{total}} = mf_{\text{air}} \Delta s_{\text{air}} + mf_{\text{C}_3\text{H}_8} \Delta s_{\text{C}_3\text{H}_8} = 0$$

and using Eq. (1). The solution may be obtained using EES to be

$$T_2 = 654.9 \text{ K}, P_2 = 1951 \text{ kPa}$$

The initial and final internal energies are (from EES)

$$T_1 = 30^\circ\text{C} \longrightarrow \begin{aligned} u_{\text{air},1} &= 216.5 \text{ kJ/kg} \\ u_{\text{C}_3\text{H}_8,1} &= -2404 \text{ kJ/kg} \end{aligned} \quad T_2 = 654.9 \text{ K} \longrightarrow \begin{aligned} u_{\text{air},2} &= 477.1 \text{ kJ/kg} \\ u_{\text{C}_3\text{H}_8,2} &= -1607 \text{ kJ/kg} \end{aligned}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$q_{\text{in}} + w_{\text{in}} = \Delta u_m \longrightarrow w_{\text{in}} = \Delta u_m$$

$$\text{where } \Delta u_m = mf_{\text{air}} (u_{\text{air},2} - u_{\text{air},1}) + mf_{\text{C}_3\text{H}_8} (u_{\text{C}_3\text{H}_8,2} - u_{\text{C}_3\text{H}_8,1})$$

$$\text{Substituting, } w_{\text{in}} = \Delta u_m = (0.9412)(477.1 - 216.5) + (0.05882)[(-1607) - (-2404)] = \mathbf{292.2 \text{ kJ/kg}}$$

13-58 The moles, temperatures, and pressures of two gases forming a mixture are given. The mixture temperature and pressure are to be determined.

Assumptions 1 Under specified conditions both CO₂ and H₂ can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** The tank is insulated and thus there is no heat transfer. **3** There are no other forms of work involved.

Properties The molar masses and specific heats of CO₂ and H₂ are 44.0 kg/kmol, 2.0 kg/kmol, 0.657 kJ/kg·°C, and 10.183 kJ/kg·°C, respectively. (Tables A-1 and A-2b).

Analysis (a) We take both gases as our system. No heat, work, or mass crosses the system boundary, therefore this is a closed system with $Q = 0$ and $W = 0$. Then the energy balance for this closed system reduces to

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ 0 &= \Delta U = \Delta U_{\text{CO}_2} + \Delta U_{\text{H}_2} \\ 0 &= [mc_v(T_m - T_1)]_{\text{CO}_2} + [mc_v(T_m - T_1)]_{\text{H}_2} \end{aligned}$$

Using c_v values at room temperature and noting that $m = NM$, the final temperature of the mixture is determined to be

$$\begin{aligned} (2.5 \times 44 \text{ kg})(0.657 \text{ kJ/kg} \cdot ^\circ\text{C})(T_m - 27^\circ\text{C}) + (7.5 \times 2 \text{ kg})(10.183 \text{ kJ/kg} \cdot ^\circ\text{C})(T_m - 40^\circ\text{C}) &= 0 \\ T_m &= 35.8^\circ\text{C} \quad (308.8 \text{ K}) \end{aligned}$$

(b) The volume of each tank is determined from

$$\begin{aligned} V_{\text{CO}_2} &= \left(\frac{NR_u T_1}{P_1} \right)_{\text{CO}_2} = \frac{(2.5 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(300 \text{ K})}{200 \text{ kPa}} = 31.18 \text{ m}^3 \\ V_{\text{H}_2} &= \left(\frac{NR_u T_1}{P_1} \right)_{\text{H}_2} = \frac{(7.5 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(313 \text{ K})}{400 \text{ kPa}} = 48.79 \text{ m}^3 \end{aligned}$$

Thus,

$$\begin{aligned} V_m &= V_{\text{CO}_2} + V_{\text{H}_2} = 31.18 \text{ m}^3 + 48.79 \text{ m}^3 = 79.97 \text{ m}^3 \\ N_m &= N_{\text{CO}_2} + N_{\text{H}_2} = 2.5 \text{ kmol} + 7.5 \text{ kmol} = 10.0 \text{ kmol} \end{aligned}$$

and

$$P_m = \frac{N_m R_u T_m}{V_m} = \frac{(10.0 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(308.8 \text{ K})}{79.97 \text{ m}^3} = 321 \text{ kPa}$$

CO ₂	H ₂
2.5 kmol	7.5 kmol
200 kPa	400 kPa
27°C	40°C

13-59 The mass fractions of components of a gas mixture are given. This mixture is compressed in a reversible, isothermal, steady-flow compressor. The work and heat transfer for this compression per unit mass of the mixture are to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of CH₄, C₃H₈, and C₄H₁₀ are 16.0, 44.0, and 58.0 kg/kmol, respectively (Table A-1).

Analysis The mole numbers of each component are

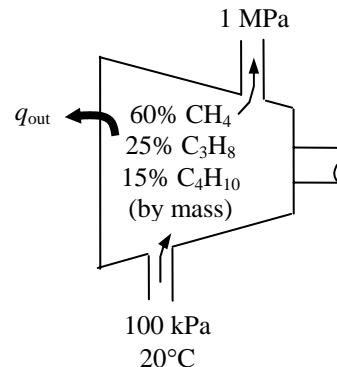

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_3\text{H}_8} = \frac{m_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.5682 \text{ kmol}$$

$$N_{\text{C}_4\text{H}_{10}} = \frac{m_{\text{C}_4\text{H}_{10}}}{M_{\text{C}_4\text{H}_{10}}} = \frac{15 \text{ kg}}{58 \text{ kg/kmol}} = 0.2586 \text{ kmol}$$

The mole number of the mixture is

$$\begin{aligned} N_m &= N_{\text{CH}_4} + N_{\text{C}_3\text{H}_8} + N_{\text{C}_4\text{H}_{10}} \\ &= 3.75 + 0.5682 + 0.2586 = 4.5768 \text{ kmol} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{4.5768 \text{ kmol}} = 21.85 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{21.85 \text{ kg/kmol}} = 0.3805 \text{ kJ/kg} \cdot \text{K}$$

For a reversible, isothermal process, the work input is

$$w_{\text{in}} = RT \ln\left(\frac{P_2}{P_1}\right) = (0.3805 \text{ kJ/kg} \cdot \text{K})(293 \text{ K}) \ln\left(\frac{1000 \text{ kPa}}{100 \text{ kPa}}\right) = 257 \text{ kJ/kg}$$

An energy balance on the control volume gives

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta \dot{E}_{\text{system}}^{\pi_0 \text{ (steady)}}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 + \dot{W}_{\text{in}} = \dot{m}h_2 + \dot{Q}_{\text{out}}$$

$$\dot{W}_{\text{in}} - \dot{Q}_{\text{out}} = \dot{m}(h_2 - h_1)$$

$$w_{\text{in}} - q_{\text{out}} = c_p(T_2 - T_1) = 0 \quad \text{since } T_2 = T_1$$

$$w_{\text{in}} = q_{\text{out}}$$

That is,

$$q_{\text{out}} = w_{\text{in}} = 257 \text{ kJ/kg}$$

13-60 The volume fractions of components of a gas mixture during the expansion process of the ideal Otto cycle are given. The thermal efficiency of this cycle is to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N₂, O₂, H₂O, and CO₂ are 28.0, 32.0, 18.0, and 44.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 1.039, 0.918, 1.8723, and 0.846 kJ/kg·K, respectively. The air properties at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$ (Table A-2a).

Analysis We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned}m_{N_2} &= N_{N_2} M_{N_2} = (30 \text{ kmol})(28 \text{ kg/kmol}) = 840 \text{ kg} \\m_{O_2} &= N_{O_2} M_{O_2} = (10 \text{ kmol})(32 \text{ kg/kmol}) = 320 \text{ kg} \\m_{H_2O} &= N_{H_2O} M_{H_2O} = (35 \text{ kmol})(18 \text{ kg/kmol}) = 630 \text{ kg} \\m_{CO_2} &= N_{CO_2} M_{CO_2} = (25 \text{ kmol})(44 \text{ kg/kmol}) = 1100 \text{ kg}\end{aligned}$$

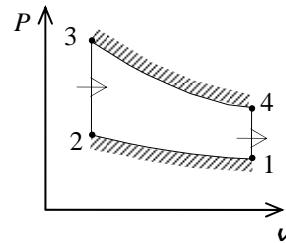

The total mass is

$$\begin{aligned}m_m &= m_{N_2} + m_{O_2} + m_{H_2O} + m_{CO_2} \\&= 840 + 320 + 630 + 1100 \\&= 2890 \text{ kg}\end{aligned}$$

30% N ₂
10% O ₂
35% H ₂ O
25% CO ₂
(by volume)

Then the mass fractions are

$$\begin{aligned}mf_{N_2} &= \frac{m_{N_2}}{m_m} = \frac{840 \text{ kg}}{2890 \text{ kg}} = 0.2907 \\mf_{O_2} &= \frac{m_{O_2}}{m_m} = \frac{320 \text{ kg}}{2890 \text{ kg}} = 0.1107 \\mf_{H_2O} &= \frac{m_{H_2O}}{m_m} = \frac{630 \text{ kg}}{2890 \text{ kg}} = 0.2180 \\mf_{CO_2} &= \frac{m_{CO_2}}{m_m} = \frac{1100 \text{ kg}}{2890 \text{ kg}} = 0.3806\end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned}c_p &= mf_{N_2} c_{p,N_2} + mf_{O_2} c_{p,O_2} + mf_{H_2O} c_{p,H_2O} + mf_{CO_2} c_{p,CO_2} \\&= 0.2907 \times 1.039 + 0.1107 \times 0.918 + 0.2180 \times 1.8723 + 0.3806 \times 0.846 \\&= 1.134 \text{ kJ/kg}\cdot\text{K}\end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2890 \text{ kg}}{100 \text{ kmol}} = 28.90 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol}\cdot\text{K}}{28.90 \text{ kg/kmol}} = 0.2877 \text{ kJ/kg}\cdot\text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 1.134 - 0.2877 = 0.846 \text{ kJ/kg}\cdot\text{K}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{1.134}{0.846} = 1.340$$

The average of the air properties at room temperature and combustion gas properties are

$$c_{p,\text{avg}} = 0.5(1.134 + 1.005) = 1.070 \text{ kJ/kg} \cdot \text{K}$$

$$c_{v,\text{avg}} = 0.5(0.846 + 0.718) = 0.782 \text{ kJ/kg} \cdot \text{K}$$

$$k_{\text{avg}} = 0.5(1.34 + 1.4) = 1.37$$

These average properties will be used for heat addition and rejection processes. For compression, the air properties at room temperature and during expansion, the mixture properties will be used. During the compression process,

$$T_2 = T_1 r^{k-1} = (288 \text{ K})(8)^{0.4} = 662 \text{ K}$$

During the heat addition process,

$$q_{\text{in}} = c_{v,\text{avg}} (T_3 - T_2) = (0.782 \text{ kJ/kg} \cdot \text{K})(1373 - 662) \text{ K} = 556 \text{ kJ/kg}$$

During the expansion process,

$$T_4 = T_3 \left(\frac{1}{r} \right)^{k-1} = (1373 \text{ K}) \left(\frac{1}{8} \right)^{0.37} = 636.1 \text{ K}$$

During the heat rejection process,

$$q_{\text{out}} = c_{v,\text{avg}} (T_4 - T_1) = (0.782 \text{ kJ/kg} \cdot \text{K})(636.1 - 288) \text{ K} = 272.2 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{272.2 \text{ kJ/kg}}{556 \text{ kJ/kg}} = \mathbf{0.511}$$

13-61 The thermal efficiency of the cycle in the previous problem is to be compared to that predicted by air standard analysis.

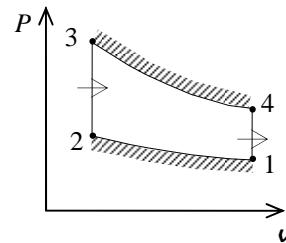

Assumptions Air-standard assumptions are applicable.

Properties The air properties at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$ (Table A-2a).

Analysis In the previous problem, the thermal efficiency of the cycle was determined to be **0.511** (51.1%). The thermal efficiency with air-standard model is determined from

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{8^{0.4}} = \mathbf{0.565}$$

which is greater than that calculated with gas mixture analysis in the previous problem.

13-62E The volume fractions of components of a gas mixture passing through the turbine of a simple ideal Brayton cycle are given. The thermal efficiency of this cycle is to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N₂, O₂, H₂O, and CO₂ are 28.0, 32.0, 18.0, and 44.0 lbm/lbmol, respectively (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.248, 0.219, 0.445, and 0.203 Btu/lbm·R, respectively. The air properties at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$, $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$, $k = 1.4$ (Table A-2Ea).

Analysis We consider 100 lbmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{N_2} &= N_{N_2} M_{N_2} = (20 \text{ lbmol})(28 \text{ lbm/lbmol}) = 560 \text{ lbm} \\ m_{O_2} &= N_{O_2} M_{O_2} = (5 \text{ lbmol})(32 \text{ lbm/lbmol}) = 160 \text{ lbm} \\ m_{H_2O} &= N_{H_2O} M_{H_2O} = (35 \text{ lbmol})(18 \text{ lbm/lbmol}) = 630 \text{ lbm} \\ m_{CO_2} &= N_{CO_2} M_{CO_2} = (40 \text{ lbmol})(44 \text{ lbm/lbmol}) = 1760 \text{ lbm} \end{aligned}$$

The total mass is

$$\begin{aligned} m_m &= m_{N_2} + m_{O_2} + m_{H_2O} + m_{CO_2} \\ &= 560 + 160 + 630 + 1760 \\ &= 3110 \text{ lbm} \end{aligned}$$

Then the mass fractions are

$$\begin{aligned} mf_{N_2} &= \frac{m_{N_2}}{m_m} = \frac{560 \text{ lbm}}{3110 \text{ lbm}} = 0.1801 \\ mf_{O_2} &= \frac{m_{O_2}}{m_m} = \frac{160 \text{ lbm}}{3110 \text{ lbm}} = 0.05145 \\ mf_{H_2O} &= \frac{m_{H_2O}}{m_m} = \frac{630 \text{ lbm}}{3110 \text{ lbm}} = 0.2026 \\ mf_{CO_2} &= \frac{m_{CO_2}}{m_m} = \frac{1760 \text{ lbm}}{3110 \text{ lbm}} = 0.5659 \end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{O_2} c_{p,O_2} + mf_{H_2O} c_{p,H_2O} + mf_{CO_2} c_{p,CO_2} \\ &= 0.1801 \times 0.248 + 0.05145 \times 0.219 + 0.2026 \times 0.445 + 0.5659 \times 0.203 \\ &= 0.2610 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{3110 \text{ lbm}}{100 \text{ lbmol}} = 31.10 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbm}\cdot\text{R}}{31.10 \text{ lbm/lbmol}} = 0.06385 \text{ Btu/lbm}\cdot\text{R}$$

Then the constant-volume specific heat is

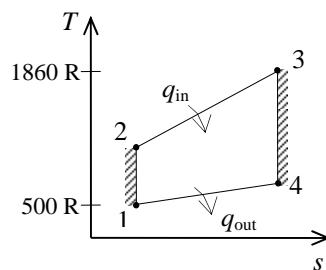

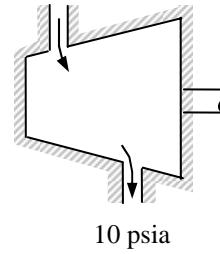

$$c_v = c_p - R = 0.2610 - 0.06385 = 0.1971 \text{ Btu/lbm}\cdot\text{R}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{0.2610}{0.1971} = 1.324$$

The average of the air properties at room temperature and combustion gas properties are

20% N₂, 5% O₂
35% H₂O, 40% CO₂
(by volume)

$$c_{p,\text{avg}} = 0.5(0.2610 + 0.240) = 0.2505 \text{ Btu/lbm} \cdot \text{R}$$

$$c_{v,\text{avg}} = 0.5(0.1971 + 0.171) = 0.1841 \text{ Btu/lbm} \cdot \text{R}$$

$$k_{\text{avg}} = 0.5(1.324 + 1.4) = 1.362$$

These average properties will be used for heat addition and rejection processes. For compression, the air properties at room temperature and during expansion, the mixture properties will be used. During the compression process,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (500 \text{ R}) (6)^{0.4/1.4} = 834.3 \text{ R}$$

During the heat addition process,

$$q_{\text{in}} = c_{p,\text{avg}} (T_3 - T_2) = (0.2505 \text{ Btu/lbm} \cdot \text{R}) (1860 - 834.3) \text{ R} = 256.9 \text{ Btu/lbm}$$

During the expansion process,

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1860 \text{ R}) \left(\frac{1}{6} \right)^{0.362/1.362} = 1155.3 \text{ R}$$

During the heat rejection process,

$$q_{\text{out}} = c_{p,\text{avg}} (T_4 - T_1) = (0.2505 \text{ Btu/lbm} \cdot \text{R}) (1155.3 - 500) \text{ R} = 164.2 \text{ Btu/lbm}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{164.2 \text{ Btu/lbm}}{256.9 \text{ Btu/lbm}} = 0.361 = \mathbf{36.1\%}$$

13-63E The thermal efficiency of the cycle in the previous problem is to be compared to that predicted by air standard analysis?

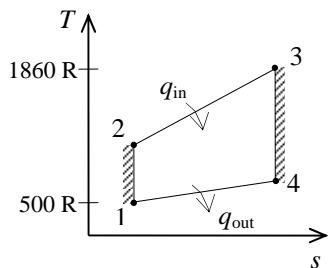

Assumptions Air-standard assumptions are applicable.

Properties The air properties at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$, $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$, $k = 1.4$ (Table A-2Ea).

Analysis In the previous problem, the thermal efficiency of the cycle was determined to be **0.361** (36.1%). The thermal efficiency with air-standard model is determined from

$$\eta_{\text{th}} = 1 - \frac{1}{r_p^{(k-1)/k}} = 1 - \frac{1}{6^{0.4/1.4}} = 0.401 = \mathbf{40.1\%}$$

which is greater than that calculated with gas mixture analysis in the previous problem.

13-64E The mass fractions of a natural gas mixture at a specified pressure and temperature trapped in a geological location are given. This natural gas is pumped to the surface. The work required is to be determined using Kay's rule and the enthalpy-departure method.

Properties The molar masses of CH₄ and C₂H₆ are 16.0 and 30.0 lbm/lbmol, respectively. The critical properties are 343.9 R, 673 psia for CH₄ and 549.8 R and 708 psia for C₂H₆ (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.532 and 0.427 Btu/lbm·R, respectively (Table A-2Ea).

Analysis We consider 100 lbm of this mixture. Then the mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ lbm}}{16 \text{ lbm/lbmol}} = 4.6875 \text{ lbmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{25 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.8333 \text{ lbmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 4.6875 + 0.8333 = 5.5208 \text{ lbmol}$$

75% CH₄
25% C₂H₆
(by mass)
2000 psia
300°F

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.6875 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.8491$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{0.8333 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.1509$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{5.5208 \text{ lbmol}} = 18.11 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbmol}\cdot\text{R}}{18.11 \text{ lbm/lbmol}} = 0.1097 \text{ Btu/lbm}\cdot\text{R}$$

The constant-pressure specific heat of the mixture is determined from

$$c_p = mf_{\text{CH}_4}c_{p,\text{CH}_4} + mf_{\text{C}_2\text{H}_6}c_{p,\text{C}_2\text{H}_6} = 0.75 \times 0.532 + 0.25 \times 0.427 = 0.506 \text{ Btu/lbm}\cdot\text{R}$$

To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{CH}_4} T_{\text{cr},\text{CH}_4} + y_{\text{C}_2\text{H}_6} T_{\text{cr},\text{C}_2\text{H}_6} \\ &= (0.8491)(343.9 \text{ R}) + (0.1509)(549.8 \text{ R}) = 375.0 \text{ R} \end{aligned}$$

$$\begin{aligned} P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{CH}_4} P_{\text{cr},\text{CH}_4} + y_{\text{C}_2\text{H}_6} P_{\text{cr},\text{C}_2\text{H}_6} \\ &= (0.8491)(673 \text{ psia}) + (0.1509)(708 \text{ psia}) = 678.3 \text{ psia} \end{aligned}$$

The compressibility factor of the gas mixture in the reservoir and the mass of this gas are

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{\text{cr},m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_R &= \frac{P_m}{P'_{\text{cr},m}} = \frac{2000 \text{ psia}}{678.3 \text{ psia}} = 2.949 \end{aligned} \right\} Z_m = 0.963 \quad (\text{Fig. A-15})$$

$$m = \frac{PV}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.963)(0.5925 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(760 \text{ R})} = 4.612 \times 10^6 \text{ lbm}$$

The enthalpy departure factors in the reservoir and the surface are (from EES or Fig. A-29)

$$\left. \begin{aligned} T_{R1} &= \frac{T_m}{T'_{cr,m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_{R1} &= \frac{P_m}{P'_{cr,m}} = \frac{2000 \text{ psia}}{678.3 \text{ psia}} = 2.949 \end{aligned} \right\} Z_{h1} = 0.703$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_m}{T'_{cr,m}} = \frac{660 \text{ R}}{375.0 \text{ R}} = 1.76 \\ P_{R2} &= \frac{P_m}{P'_{cr,m}} = \frac{20 \text{ psia}}{678.3 \text{ psia}} = 0.0295 \end{aligned} \right\} Z_{h2} = 0.0112$$

The enthalpy change for the ideal gas mixture is

$$(h_1 - h_2)_{\text{ideal}} = c_p(T_1 - T_2) = (0.506 \text{ Btu/lbm}\cdot\text{R})(760 - 660)\text{R} = 50.6 \text{ Btu/lbm}$$

The enthalpy change with departure factors is

$$\begin{aligned} h_1 - h_2 &= (h_1 - h_2)_{\text{ideal}} - RT'_{cr,m}(Z_{h1} - Z_{h2}) \\ &= 50.6 - (0.1096)(375)(0.703 - 0.0112) \\ &= 22.12 \text{ Btu/lbm} \end{aligned}$$

The work input is then

$$W_{\text{in}} = m(h_1 - h_2) = (4.612 \times 10^6 \text{ lbm})(22.12 \text{ Btu/lbm}) = \mathbf{1.02 \times 10^8 \text{ Btu}}$$

13-65E A gas mixture with known mass fractions is accelerated through a nozzle from a specified state to a specified pressure. For a specified isentropic efficiency, the exit temperature and the exit velocity of the mixture are to be determined.

Assumptions 1 Under specified conditions both N₂ and CO₂ can be treated as ideal gases, and the mixture as an ideal gas mixture. 2 The nozzle is adiabatic and thus heat transfer is negligible. 3 This is a steady-flow process. 4 Potential energy changes are negligible.

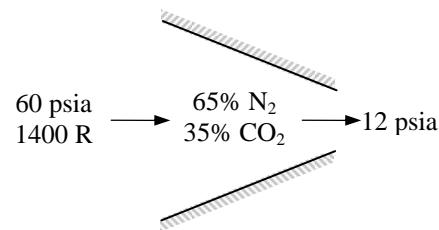

Properties The specific heats of N₂ and CO₂ are $c_{p,N_2} = 0.248 \text{ Btu/lbm.R}$, $c_{v,N_2} = 0.177 \text{ Btu/lbm.R}$, $c_{p,CO_2} = 0.203 \text{ Btu/lbm.R}$, and $c_{v,CO_2} = 0.158 \text{ Btu/lbm.R}$. (Table A-2E).

Analysis (a) Under specified conditions both N₂ and CO₂ can be treated as ideal gases, and the mixture as an ideal gas mixture. The c_p , c_v , and k values of this mixture are determined from

$$\begin{aligned} c_{p,m} &= \sum mf_i c_{p,i} = mf_{N_2} c_{p,N_2} + mf_{CO_2} c_{p,CO_2} \\ &= (0.65)(0.248) + (0.35)(0.203) \\ &= 0.2323 \text{ Btu/lbm.R} \end{aligned}$$

$$\begin{aligned} c_{v,m} &= \sum mf_i c_{v,i} = mf_{N_2} c_{v,N_2} + mf_{CO_2} c_{v,CO_2} \\ &= (0.65)(0.177) + (0.35)(0.158) \\ &= 0.1704 \text{ Btu/lbm.R} \end{aligned}$$

$$k_m = \frac{c_{p,m}}{c_{v,m}} = \frac{0.2323 \text{ Btu/lbm.R}}{0.1704 \text{ Btu/lbm.R}} = 1.363$$

Therefore, the N₂-CO₂ mixture can be treated as a single ideal gas with above properties. Then the isentropic exit temperature can be determined from

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (1400 \text{ R}) \left(\frac{12 \text{ psia}}{60 \text{ psia}} \right)^{0.363/1.363} = 911.7 \text{ R}$$

From the definition of isentropic efficiency,

$$\eta_N = \frac{h_1 - h_2}{h_1 - h_{2s}} = \frac{c_p(T_1 - T_2)}{c_p(T_1 - T_{2s})} \longrightarrow 0.88 = \frac{1400 - T_2}{1400 - 911.7} \longrightarrow T_2 = 970.3 \text{ R}$$

(b) Noting that, $q = w = 0$, from the steady-flow energy balance relation,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{sg0 (steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2$$

$$0 = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$V_2 = \sqrt{2c_p(T_1 - T_2)} = \sqrt{2(0.2323 \text{ Btu/lbm.R})(1400 - 970.3) \text{ R} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 2236 \text{ ft/s}$$

13-66E Problem 13-65E is reconsidered. The problem is first to be solved and then, for all other conditions being the same, the problem is to be resolved to determine the composition of the nitrogen and carbon dioxide that is required to have an exit velocity of 2200 ft/s at the nozzle exit.

Analysis The problem is solved using EES, and the solution is given below.

13-67 A mixture of hydrogen and oxygen is considered. The entropy change of this mixture between the two specified states is to be determined.

Assumptions Hydrogen and oxygen are ideal gases.

Properties The gas constants of hydrogen and oxygen are 4.124 and 0.2598 kJ/kg·K, respectively (Table A-1).

Analysis The effective gas constant of this mixture is

$R = m_f H_2 R_{H_2} + m_f O_2 R_{O_2} = (0.33)(4.1240) + (0.67)(0.2598) = 1.5350 \text{ kJ/kg} \cdot \text{K}$ Since the temperature of the two states is the same, the entropy change is determined from

$$s_2 - s_1 = -R \ln \frac{P_2}{P_1} = -(1.5350 \text{ kJ/kg} \cdot \text{K}) \ln \frac{150 \text{ kPa}}{750 \text{ kPa}} = \mathbf{2.470 \text{ kJ/kg} \cdot \text{K}}$$

13-68 A piston-cylinder device contains a gas mixture at a given state. Heat is transferred to the mixture. The amount of heat transfer and the entropy change of the mixture are to be determined.

Assumptions 1 Under specified conditions both H_2 and N_2 can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** Kinetic and potential energy changes are negligible.

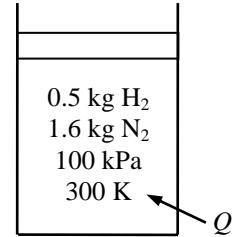

Properties The constant pressure specific heats of H_2 and N_2 at 450 K are 14.501 kJ/kg·K and 1.049 kJ/kg·K, respectively. (Table A-2b).

Analysis (a) Noting that $P_2 = P_1$ and $V_2 = 2V_1$,

$$\frac{P_2 V_2}{T_2} = \frac{P_1 V_1}{T_1} \longrightarrow T_2 = \frac{2V_1}{V_1} T_1 = 2T_1 = (2)(300 \text{ K}) = 600 \text{ K}$$

From the closed system energy balance relation,

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ Q_{\text{in}} - W_{b,\text{out}} &= \Delta U \rightarrow Q_{\text{in}} = \Delta H \end{aligned}$$

since W_b and ΔU combine into ΔH for quasi-equilibrium constant pressure processes.

$$\begin{aligned} Q_{\text{in}} &= \Delta H = \Delta H_{H_2} + \Delta H_{N_2} = [mc_{p,\text{avg}}(T_2 - T_1)]_{H_2} + [mc_{p,\text{avg}}(T_2 - T_1)]_{N_2} \\ &= (0.5 \text{ kg})(14.501 \text{ kJ/kg} \cdot \text{K})(600 - 300) \text{ K} + (1.6 \text{ kg})(1.049 \text{ kJ/kg} \cdot \text{K})(600 - 300) \text{ K} \\ &= \mathbf{2679 \text{ kJ}} \end{aligned}$$

(b) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of the mixture during this process is

$$\begin{aligned} \Delta S_{H_2} &= [m(s_2 - s_1)]_{H_2} = m_{H_2} \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{H_2}^{\phi_0} = m_{H_2} \left(c_p \ln \frac{T_2}{T_1} \right)_{H_2} \\ &= (0.5 \text{ kg})(14.501 \text{ kJ/kg} \cdot \text{K}) \ln \frac{600 \text{ K}}{300 \text{ K}} \\ &= 5.026 \text{ kJ/K} \end{aligned}$$

$$\begin{aligned} \Delta S_{N_2} &= [m(s_2 - s_1)]_{N_2} = m_{N_2} \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{N_2}^{\phi_0} = m_{N_2} \left(c_p \ln \frac{T_2}{T_1} \right)_{N_2} \\ &= (1.6 \text{ kg})(1.049 \text{ kJ/kg} \cdot \text{K}) \ln \frac{600 \text{ K}}{300 \text{ K}} \\ &= 1.163 \text{ kJ/K} \end{aligned}$$

$$\Delta S_{\text{total}} = \Delta S_{H_2} + \Delta S_{N_2} = 5.026 \text{ kJ/K} + 1.163 \text{ kJ/K} = \mathbf{6.19 \text{ kJ/K}}$$

13-69 The temperatures and pressures of two gases forming a mixture in a mixing chamber are given. The mixture temperature and the rate of entropy generation are to be determined.

Assumptions 1 Under specified conditions both C_2H_6 and CH_4 can be treated as ideal gases, and the mixture as an ideal gas mixture. 2 The mixing chamber is insulated and thus there is no heat transfer. 3 There are no other forms of work involved. 3 This is a steady-flow process. 4 The kinetic and potential energy changes are negligible.

Properties The specific heats of C_2H_6 and CH_4 are 1.7662 kJ/kg·°C and 2.2537 kJ/kg·°C, respectively. (Table A-2b).

Analysis (a) The enthalpy of ideal gases is independent of pressure, and thus the two gases can be treated independently even after mixing. Noting that

$\dot{W} = \dot{Q} = 0$, the steady-flow energy balance equation reduces to

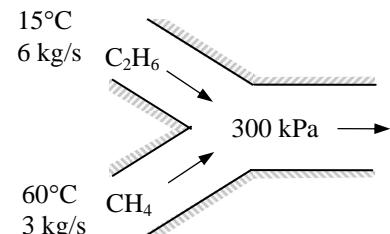

$$\dot{E}_{in} - \dot{E}_{out} = \Delta\dot{E}_{system}^{\text{0(steady)}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i = \dot{m}_{C_2H_6} (h_e - h_i)_{C_2H_6} + \dot{m}_{CH_4} (h_e - h_i)_{CH_4}$$

$$0 = [\dot{m} c_p (T_e - T_i)]_{C_2H_6} + [\dot{m} c_p (T_e - T_i)]_{CH_4}$$

Using c_p values at room temperature and substituting, the exit temperature of the mixture becomes

$$0 = (6 \text{ kg/s})(1.7662 \text{ kJ/kg} \cdot \text{°C})(T_m - 15^\circ\text{C}) + (3 \text{ kg/s})(2.2537 \text{ kJ/kg} \cdot \text{°C})(T_m - 60^\circ\text{C})$$

$$T_m = 32.5^\circ\text{C} \quad (305.5 \text{ K})$$

(b) The rate of entropy change associated with this process is determined from an entropy balance on the mixing chamber,

$$\dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} = \Delta\dot{S}_{system}^{\text{0}} = 0$$

$$[\dot{m}(s_1 - s_2)]_{C_2H_6} + [\dot{m}(s_1 - s_2)]_{CH_4} + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = [\dot{m}(s_2 - s_1)]_{C_2H_6} + [\dot{m}(s_2 - s_1)]_{CH_4}$$

The molar flow rate of the two gases in the mixture is

$$\dot{N}_{C_2H_6} = \left(\frac{\dot{m}}{M} \right)_{C_2H_6} = \frac{6 \text{ kg/s}}{30 \text{ kg/kmol}} = 0.2 \text{ kmol/s}$$

$$\dot{N}_{CH_4} = \left(\frac{\dot{m}}{M} \right)_{CH_4} = \frac{4.5 \text{ kg/s}}{16 \text{ kg/kmol}} = 0.1875 \text{ kmol/s}$$

Then the mole fraction of each gas becomes

$$y_{C_2H_6} = \frac{0.2}{0.2 + 0.1875} = 0.5161$$

$$y_{CH_4} = \frac{0.1875}{0.2 + 0.1875} = 0.4839$$

Thus,

$$(s_2 - s_1)_{C_2H_6} = \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{C_2H_6} = \left(c_p \ln \frac{T_2}{T_1} - R \ln y \right)_{C_2H_6}$$

$$= (1.7662 \text{ kJ/kg} \cdot \text{K}) \ln \frac{305.5 \text{ K}}{288 \text{ K}} - (0.2765 \text{ kJ/kg} \cdot \text{K}) \ln(0.5161) = 0.2872 \text{ kJ/kg} \cdot \text{K}$$

$$(s_2 - s_1)_{CH_4} = \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{CH_4} = \left(c_p \ln \frac{T_2}{T_1} - R \ln y \right)_{CH_4}$$

$$= (2.2537 \text{ kJ/kg} \cdot \text{K}) \ln \frac{305.5 \text{ K}}{333 \text{ K}} - (0.5182 \text{ kJ/kg} \cdot \text{K}) \ln(0.4839) = 0.1821 \text{ kJ/kg} \cdot \text{K}$$

Noting that $P_{m,2} = P_{i,1} = 300 \text{ kPa}$ and substituting,

$$\dot{S}_{gen} = (6 \text{ kg/s})(0.2872 \text{ kJ/kg} \cdot \text{K}) + (3 \text{ kg/s})(0.1821 \text{ kJ/kg} \cdot \text{K}) = 2.27 \text{ kW/K}$$

13-70 Problem 13-69 is reconsidered. The effect of the mass fraction of methane in the mixture on the mixture temperature and the rate of exergy destruction is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

13-71E In an air-liquefaction plant, it is proposed that the pressure and temperature of air be adiabatically reduced. It is to be determined whether this process is possible and the work produced is to be determined using Kay's rule and the departure charts.

Assumptions Air is a gas mixture with 21% O₂ and 79% N₂, by mole.

Properties The molar masses of O₂ and N₂ are 32.0 and 28.0 lbm/lbmol, respectively. The critical properties are 278.6 R, 736 psia for O₂ and 227.1 R and 492 psia for N₂ (Table A-1E).

Analysis To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{O}_2} T_{\text{cr},\text{O}_2} + y_{\text{N}_2} T_{\text{cr},\text{N}_2} \\ &= (0.21)(278.6 \text{ R}) + (0.79)(227.1 \text{ R}) = 237.9 \text{ R} \\ P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{O}_2} P_{\text{cr},\text{O}_2} + y_{\text{N}_2} P_{\text{cr},\text{N}_2} \\ &= (0.21)(736 \text{ psia}) + (0.79)(492 \text{ psia}) = 543.2 \text{ psia} \end{aligned}$$

21% O ₂
79% N ₂
(by mole)
1500 psia
40°F

The enthalpy and entropy departure factors at the initial and final states are (from EES)

$$\left. \begin{array}{l} T_{R1} = \frac{T_{m1}}{T'_{\text{cr},m}} = \frac{500 \text{ R}}{237.9 \text{ R}} = 2.102 \\ P_{R1} = \frac{P_{m1}}{P'_{\text{cr},m}} = \frac{1500 \text{ psia}}{432.2 \text{ psia}} = 3.471 \\ \\ T_{R2} = \frac{T_{m2}}{T'_{\text{cr},m}} = \frac{360 \text{ R}}{237.9 \text{ R}} = 1.513 \\ P_{R2} = \frac{P_{m2}}{P'_{\text{cr},m}} = \frac{15 \text{ psia}}{432.2 \text{ psia}} = 0.0347 \end{array} \right\} \begin{array}{l} Z_{h1} = 0.725 \\ Z_{s1} = 0.339 \\ \\ Z_{h2} = 0.0179 \\ Z_{s2} = 0.00906 \end{array}$$

The enthalpy and entropy changes of the air under the ideal gas assumption is (Properties are from Table A-17E)

$$(h_2 - h_1)_{\text{ideal}} = 85.97 - 119.48 = -33.5 \text{ Btu/lbm}$$

$$(s_2 - s_1)_{\text{ideal}} = s_2^{\circ} - s_1^{\circ} - R \ln \frac{P_2}{P_1} = 0.50369 - 0.58233 - (0.06855) \ln \frac{15}{1500} = 0.2370 \text{ Btu/lbm} \cdot \text{R}$$

With departure factors, the enthalpy change (i.e., the work output) and the entropy change are

$$\begin{aligned} w_{\text{out}} &= h_1 - h_2 = (h_1 - h_2)_{\text{ideal}} - RT'_{\text{cr}}(Z_{h1} - Z_{h2}) \\ &= 33.5 - (0.06855)(237.9)(0.725 - 0.0179) = \mathbf{22.0 \text{ Btu/lbm}} \end{aligned}$$

$$\begin{aligned} s_2 - s_1 &= (s_2 - s_1)_{\text{ideal}} - R(Z_{s2} - Z_{s1}) \\ &= 0.2370 - (0.06855)(0.00906 - 0.339) = \mathbf{0.2596 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

The entropy change in this case is equal to the entropy generation during the process since the process is adiabatic. The positive value of entropy generation shows that this process is possible.

13-72 Heat is transferred to a gas mixture contained in a piston cylinder device. The initial state and the final temperature are given. The heat transfer is to be determined for the ideal gas and non-ideal gas cases.

Properties The molar masses of H₂ and N₂ are 2.0, and 28.0 kg/kmol. (Table A-1).

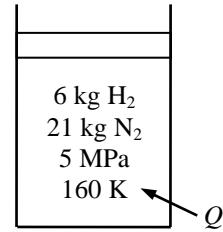

Analysis From the energy balance relation,

$$E_{\text{in}} - E_{\text{out}} = \Delta E$$

$$Q_{\text{in}} - W_{b,\text{out}} = \Delta U$$

$$Q_{\text{in}} = \Delta H = \Delta H_{\text{H}_2} + \Delta H_{\text{N}_2} = N_{\text{H}_2} (\bar{h}_2 - \bar{h}_1)_{\text{H}_2} + N_{\text{N}_2} (\bar{h}_2 - \bar{h}_1)_{\text{N}_2}$$

since W_b and ΔU combine into ΔH for quasi-equilibrium constant pressure processes

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{6 \text{ kg}}{2 \text{ kg/kmol}} = 3 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{21 \text{ kg}}{28 \text{ kg/kmol}} = 0.75 \text{ kmol}$$

(a) Assuming ideal gas behavior, the inlet and exit enthalpies of H₂ and N₂ are determined from the ideal gas tables to be

$$\text{H}_2: \quad \bar{h}_1 = \bar{h}_{@160 \text{ K}} = 4,535.4 \text{ kJ/kmol}, \quad \bar{h}_2 = \bar{h}_{@200 \text{ K}} = 5,669.2 \text{ kJ/kmol}$$

$$\text{N}_2: \quad \bar{h}_1 = \bar{h}_{@160 \text{ K}} = 4,648 \text{ kJ/kmol}, \quad \bar{h}_2 = \bar{h}_{@200 \text{ K}} = 5,810 \text{ kJ/kmol}$$

Thus, $Q_{\text{ideal}} = 3 \times (5,669.2 - 4,535.4) + 0.75 \times (5,810 - 4,648) = 4273 \text{ kJ}$

(b) Using Amagat's law and the generalized enthalpy departure chart, the enthalpy change of each gas is determined to be

$$\left. \begin{aligned} T_{R_1, \text{H}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{H}_2}} = \frac{160}{33.3} = 4.805 \\ \text{H}_2: \quad P_{R_1, \text{H}_2} &= P_{R_2, \text{H}_2} = \frac{P_m}{P_{\text{cr}, \text{H}_2}} = \frac{5}{1.30} = 3.846 \\ T_{R_2, \text{H}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{H}_2}} = \frac{200}{33.3} = 6.006 \end{aligned} \right\} \begin{array}{l} Z_{h_1} \approx 0 \\ Z_{h_2} \approx 0 \end{array} \quad (\text{Fig. A-29})$$

Thus H₂ can be treated as an ideal gas during this process.

$$\left. \begin{aligned} T_{R_1, \text{N}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{N}_2}} = \frac{160}{126.2} = 1.27 \\ \text{N}_2: \quad P_{R_1, \text{N}_2} &= P_{R_2, \text{N}_2} = \frac{P_m}{P_{\text{cr}, \text{N}_2}} = \frac{5}{3.39} = 1.47 \\ T_{R_2, \text{N}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{N}_2}} = \frac{200}{126.2} = 1.58 \end{aligned} \right\} \begin{array}{l} Z_{h_1} = 1.3 \\ Z_{h_2} = 0.7 \end{array} \quad (\text{Fig. A-29})$$

Therefore,

$$(\bar{h}_2 - \bar{h}_1)_{\text{H}_2} = (\bar{h}_2 - \bar{h}_1)_{\text{H}_2, \text{ideal}} = 5,669.2 - 4,535.4 = 1,133.8 \text{ kJ/kmol}$$

$$\begin{aligned} (\bar{h}_2 - \bar{h}_1)_{\text{N}_2} &= R_u T_{\text{cr}} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314 \text{ kPa} \cdot \text{m}^3 / \text{kmol} \cdot \text{K})(126.2 \text{ K})(1.3 - 0.7) + (5,810 - 4,648) \text{ kJ/kmol} = 1,791.5 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$Q_{\text{in}} = (3 \text{ kmol})(1,133.8 \text{ kJ/kmol}) + (0.75 \text{ kmol})(1,791.5 \text{ kJ/kmol}) = 4745 \text{ kJ}$$

13-73 Heat is transferred to a gas mixture contained in a piston cylinder device discussed in previous problem. The total entropy change and the exergy destruction are to be determined for two cases.

Analysis The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the piston-cylinder device and its immediate surroundings so that the boundary temperature of the extended system is the environment temperature at all times. It gives

$$\begin{aligned} S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} &= \Delta S_{\text{system}} \\ \frac{Q_{\text{in}}}{T_{\text{boundary}}} + S_{\text{gen}} &= \Delta S_{\text{water}} \rightarrow S_{\text{gen}} = m(s_2 - s_1) - \frac{Q_{\text{in}}}{T_{\text{surr}}} \end{aligned}$$

Then the exergy destroyed during a process can be determined from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$.

(a) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of a component in the mixture during this process is

$$\Delta S_i = m_i \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2^{\ddagger 0}}{P_1} \right)_i = m_i c_{p,i} \ln \frac{T_2}{T_1}$$

Assuming ideal gas behavior and using c_p values at the average temperature, the ΔS of H₂ and N₂ are determined from

$$\Delta S_{\text{H}_2,\text{ideal}} = (6 \text{ kg})(13.60 \text{ kJ/kg} \cdot \text{K}) \ln \frac{200 \text{ K}}{160 \text{ K}} = 18.21 \text{ kJ/K}$$

$$\Delta S_{\text{N}_2,\text{ideal}} = (21 \text{ kg})(1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{200 \text{ K}}{160 \text{ K}} = 4.87 \text{ kJ/K}$$

and

$$S_{\text{gen}} = 18.21 \text{ kJ/K} + 4.87 \text{ kJ/K} - \frac{4273 \text{ kJ}}{303 \text{ K}} = \mathbf{8.98 \text{ kJ/K}}$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (303 \text{ K})(8.98 \text{ kJ/K}) = \mathbf{2721 \text{ kJ}}$$

(b) Using Amagat's law and the generalized entropy departure chart, the entropy change of each gas is determined to be

$$\left. \begin{array}{l} T_{R_1,\text{H}_2} = \frac{T_{m,1}}{T_{\text{cr},\text{H}_2}} = \frac{160}{33.3} = 4.805 \\ P_{R_1,\text{H}_2} = P_{R_2,\text{H}_2} = \frac{P_m}{P_{\text{cr},\text{H}_2}} = \frac{5}{1.30} = 3.846 \\ T_{R_2,\text{H}_2} = \frac{T_{m,2}}{T_{\text{cr},\text{H}_2}} = \frac{200}{33.3} = 6.006 \end{array} \right\} \begin{array}{l} Z_{s_1} \approx 1 \\ Z_{s_2} \approx 1 \end{array} \quad (\text{Table A-30})$$

Thus H₂ can be treated as an ideal gas during this process.

$$\left. \begin{array}{l} T_{R_1,\text{N}_2} = \frac{T_{m,1}}{T_{\text{cr},\text{N}_2}} = \frac{160}{126.2} = 1.268 \\ P_{R_1,\text{N}_2} = P_{R_2,\text{N}_2} = \frac{P_m}{P_{\text{cr},\text{N}_2}} = \frac{5}{3.39} = 1.475 \\ T_{R_2,\text{N}_2} = \frac{T_{m,2}}{T_{\text{cr},\text{N}_2}} = \frac{200}{126.2} = 1.585 \end{array} \right\} \begin{array}{l} Z_{s_1} = 0.8 \\ Z_{s_2} = 0.4 \end{array} \quad (\text{Table A-30})$$

Therefore,

$$\Delta S_{H_2} = \Delta S_{H_2,\text{ideal}} = 18.21 \text{ kJ/K}$$

$$\begin{aligned}\Delta S_{N_2} &= N_{N_2} R_u (Z_{s_1} - Z_{s_2}) + \Delta S_{N_2,\text{ideal}} \\ &= (0.75 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(0.8 - 0.4) + (4.87 \text{ kJ/K}) \\ &= 7.37 \text{ kJ/K}\end{aligned}$$

$$\Delta S_{\text{surr}} = \frac{Q_{\text{surr}}}{T_0} = \frac{-4745 \text{ kJ}}{303 \text{ K}} = -15.66 \text{ kJ/K}$$

and

$$S_{\text{gen}} = 18.21 \text{ kJ/K} + 7.37 \text{ kJ/K} - \frac{4745 \text{ kJ}}{303 \text{ K}} = \mathbf{9.92 \text{ kJ/K}}$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (303 \text{ K})(9.92 \text{ kJ/K}) = \mathbf{3006 \text{ kJ}}$$

13-74 Air is compressed isothermally in a steady-flow device. The power input to the compressor and the rate of heat rejection are to be determined for ideal and non-ideal gas cases.

Assumptions 1 This is a steady-flow process. **2** The kinetic and potential energy changes are negligible.

Properties The molar mass of air is 28.97 kg/kmol. (Table A-1).

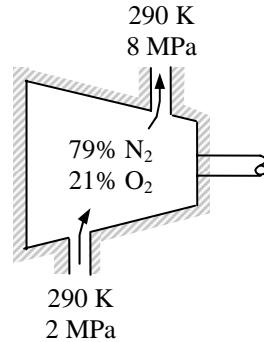

Analysis The mass flow rate of air can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{1.75 \text{ kg/s}}{28.97 \text{ kg/kmol}} = 0.06041 \text{ kmol/s}$$

(a) Assuming ideal gas behavior, the Δh and Δs of air during this process is

$$\Delta\bar{h} = 0 \text{ (isothermal process)}$$

$$\begin{aligned}\Delta\bar{s} &= \bar{c}_p \ln \frac{T_2}{T_1} - R_u \ln \frac{P_2}{P_1} = -R_u \ln \frac{P_2}{P_1} \\ &= -(8.314 \text{ kJ/kg} \cdot \text{K}) \ln \frac{8 \text{ MPa}}{2 \text{ MPa}} = -11.53 \text{ kJ/kmol} \cdot \text{K}\end{aligned}$$

Disregarding any changes in kinetic and potential energies, the steady-flow energy balance equation for the isothermal process of an ideal gas reduces to

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta\dot{E}_{\text{system}}^{\pi 0(\text{steady})} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{W}_{\text{in}} + \dot{N}\bar{h}_1 &= \dot{Q}_{\text{out}} + \dot{N}\bar{h}_2 \\ \dot{W}_{\text{in}} - \dot{Q}_{\text{out}} &= \dot{N}\Delta\bar{h}^{\pi 0} = 0 \longrightarrow \dot{W}_{\text{in}} = \dot{Q}_{\text{out}}\end{aligned}$$

Also for an isothermal, internally reversible process the heat transfer is related to the entropy change by

$$Q = T\Delta S = NT\Delta\bar{s},$$

$$\dot{Q} = \dot{N}T\Delta\bar{s} = (0.06041 \text{ kmol/s})(290 \text{ K})(-11.53 \text{ kJ/kmol} \cdot \text{K}) = -201.9 \text{ kW} \rightarrow \dot{Q}_{\text{out}} = 201.9 \text{ kW}$$

Therefore,

$$\dot{W}_{\text{in}} = \dot{Q}_{\text{out}} = \mathbf{201.9 \text{ kW}}$$

(b) Using Amagat's law and the generalized charts, the enthalpy and entropy changes of each gas are determined from

$$\begin{aligned}\bar{h}_2 - \bar{h}_1 &= R_u T_{cr}(Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}}^{\pi 0} \\ \bar{s}_2 - \bar{s}_1 &= R_u(Z_{s_1} - Z_{s_2}) + (\bar{s}_2 - \bar{s}_1)_{\text{ideal}}\end{aligned}$$

where

$$\left. \begin{aligned} P_{R_1} &= \frac{P_{m,1}}{P_{cr,N_2}} = \frac{2}{3.39} = 0.59 \\ T_{R_1} &= T_{R_2} = \frac{T_m}{T_{cr,N_2}} = \frac{290}{126.2} = 2.298 \\ P_{R_2} &= \frac{P_{m,2}}{P_{cr,N_2}} = \frac{8}{3.39} = 2.36 \end{aligned} \right\} \begin{aligned} Z_{h_1} &= 0.1154, Z_{s_1} = 0.05136 \\ Z_{h_2} &= 0.4136, Z_{s_2} = 0.1903 \end{aligned} \quad (\text{Figures A-29 and A-30 or EES})$$

Note that we used EES to obtain enthalpy and entropy departure factors. The accurate readings like these are not possible with Figures A-29 and A-30. EES has built-in functions for enthalpy departure and entropy departure factors in the following format:

`Z_h1=ENTHDEP(T_R1, P_R1)` "the function that returns enthalpy departure factor"

`Z_s1=ENTRDEP(T_R1, P_R1)` "the function that returns entropy departure factor"

$$\left. \begin{array}{l} P_{R_1} = \frac{P_{m,1}}{P_{cr,O_2}} = \frac{2}{5.08} = 0.3937 \\ O_2: \quad T_{R_1} = T_{R_2} = \frac{T_m}{T_{cr,O_2}} = \frac{290}{154.8} = 1.873 \\ P_{R_2} = \frac{P_{m,2}}{P_{cr,O_2}} = \frac{8}{5.08} = 1.575 \end{array} \right\} \begin{array}{l} Z_{h_1} = 0.1296, Z_{s_1} = 0.05967 \\ Z_{h_2} = 0.4956, Z_{s_2} = 0.2313 \end{array} \quad (\text{Figures A-29 and A-30 or EES})$$

Then,

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= y_i \Delta \bar{h}_i = y_{N_2} (\bar{h}_2 - \bar{h}_1)_{N_2} + y_{O_2} (\bar{h}_2 - \bar{h}_1)_{O_2} \\ &= (0.79)(8.314)(126.2)(0.1154 - 0.4136) + (0.21)(8.314)(154.8)(0.1296 - 0.4956) + 0 \\ &= -346.1 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= y_i \Delta \bar{s}_i = y_{N_2} (\bar{s}_2 - \bar{s}_1)_{N_2} + y_{O_2} (\bar{s}_2 - \bar{s}_1)_{O_2} \\ &= (0.79)(8.314)(0.05136 - 0.1903) + (0.21)(8.314)(0.05967 - 0.2313) + (-11.53) \\ &= -12.74 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

Thus,

$$\dot{Q}_{out} = -\dot{N}T\Delta\bar{s} = -(0.06041 \text{ kmol/s})(290 \text{ K})(-12.74 \text{ kJ/kmol} \cdot \text{K}) = 223.2 \text{ kW}$$

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{\text{system}}^{\text{0 (steady)}} = 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \dot{W}_{in} + \dot{N}\bar{h}_1 &= \dot{Q}_{out} + \dot{N}\bar{h}_2 \\ \dot{W}_{in} &= \dot{Q}_{out} + \dot{N}(\bar{h}_2 - \bar{h}_1) \longrightarrow \dot{W}_{in} = 223.2 \text{ kW} + (0.06041 \text{ kmol/s})(-346.1 \text{ kJ/kmol}) = 202.3 \text{ kW} \end{aligned}$$

13-75 Problem 13-74 is reconsidered. The results obtained by assuming ideal behavior, real gas behavior with Amagat's law, and real gas behavior with EES data are to be compared.

Analysis The problem is solved using EES, and the solution is given below.

"Given"

$y_{N2}=0.79$
 $y_{O2}=0.21$
 $T=290 \text{ [K]}$
 $P_1=2000 \text{ [kPa]}$
 $P_2=8000 \text{ [kPa]}$
 $m_{dot}=1.75 \text{ [kg/s]}$

13-76 Two mass streams of two different ideal gases are mixed in a steady-flow chamber while receiving energy by heat transfer from the surroundings. Expressions for the final temperature and the exit volume flow rate are to be obtained and two special cases are to be evaluated.

Assumptions Kinetic and potential energy changes are negligible.

Analysis (a) Mass and Energy Balances for the mixing process:

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$$

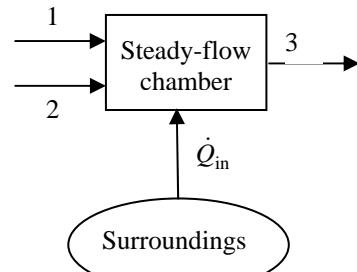

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 + \dot{Q}_{in} = \dot{m}_3 h_3$$

$$h = C_p T$$

$$\dot{m}_1 C_{P,1} T_1 + \dot{m}_2 C_{P,2} T_2 + \dot{Q}_{in} = \dot{m}_3 C_{P,m} T_3$$

$$C_{P,m} = \frac{\dot{m}_1}{\dot{m}_3} C_{P,1} + \frac{\dot{m}_2}{\dot{m}_3} C_{P,2}$$

$$T_3 = \frac{\dot{m}_1 C_{P,1}}{\dot{m}_3 C_{P,m}} T_1 + \frac{\dot{m}_2 C_{P,2}}{\dot{m}_3 C_{P,m}} T_2 + \frac{\dot{Q}_{in}}{\dot{m}_3 C_{P,m}}$$

(b) The expression for the exit volume flow rate is obtained as follows:

$$\dot{V}_3 = \dot{m}_3 v_3 = \dot{m}_3 \frac{R_3 T_3}{P_3}$$

$$\dot{V}_3 = \frac{\dot{m}_3 R_3}{P_3} \left[\frac{\dot{m}_1 C_{P,1}}{\dot{m}_3 C_{P,m}} T_1 + \frac{\dot{m}_2 C_{P,2}}{\dot{m}_3 C_{P,m}} T_2 + \frac{\dot{Q}_{in}}{\dot{m}_3 C_{P,m}} \right]$$

$$\dot{V}_3 = \frac{C_{P,1} R_3}{C_{P,m} R_1} \frac{\dot{m}_1 R_1 T_1}{P_3} + \frac{C_{P,2} R_3}{C_{P,m} R_2} \frac{\dot{m}_2 R_2 T_2}{P_3} + \frac{R_3 \dot{Q}_{in}}{P_3 C_{P,m}}$$

$$P_3 = P_1 = P_2$$

$$\dot{V}_3 = \frac{C_{P,1} R_3}{C_{P,m} R_1} \dot{V}_1 + \frac{C_{P,2} R_3}{C_{P,m} R_2} \dot{V}_2 + \frac{R_3 \dot{Q}_{in}}{P_3 C_{P,m}}$$

$$R = \frac{R_u}{M}, \quad \frac{R_3}{R_1} = \frac{R_u}{M_3} \frac{M_1}{R_u} = \frac{M_1}{M_3}, \quad \frac{R_3}{R_2} = \frac{M_2}{M_3}$$

$$\dot{V}_3 = \frac{C_{P,1} M_1}{C_{P,m} M_3} \dot{V}_1 + \frac{C_{P,2} M_2}{C_{P,m} M_3} \dot{V}_2 + \frac{R_u \dot{Q}_{in}}{P_3 M_3 C_{P,m}}$$

The mixture molar mass M_3 is found as follows:

$$M_3 = \sum y_i M_i, \quad y_i = \frac{m_{fi} / M_i}{\sum m_{fi} / M_i}, \quad m_{fi} = \frac{\dot{m}_i}{\sum \dot{m}_i}$$

(c) For adiabatic mixing \dot{Q}_{in} is zero, and the mixture volume flow rate becomes

$$\dot{V}_3 = \frac{C_{P,1} M_1}{C_{P,m} M_3} \dot{V}_1 + \frac{C_{P,2} M_2}{C_{P,m} M_3} \dot{V}_2$$

(d) When adiabatically mixing the same two ideal gases, the mixture volume flow rate becomes

$$M_3 = M_1 = M_2$$

$$C_{P,3} = C_{P,1} = C_{P,2}$$

$$\dot{V}_3 = \dot{V}_1 + \dot{V}_2$$

Special Topic: Chemical Potential and the Separation Work of Mixtures

13-77C No, a process that separates a mixture into its components without requiring any work (exergy) input is impossible since such a process would violate the 2nd law of thermodynamics.

13-78C Yes, the volume of the mixture can be more or less than the sum of the initial volumes of the mixing liquids because of the attractive or repulsive forces acting between dissimilar molecules.

13-79C The person who claims that the temperature of the mixture can be higher than the temperatures of the components is right since the total enthalpy of the mixture of two components at the same pressure and temperature, in general, is not equal to the sum of the total enthalpies of the individual components before mixing, the difference being the enthalpy (or heat) of mixing, which is the heat released or absorbed as two or more components are mixed isothermally.

13-80C Mixtures or solutions in which the effects of molecules of different components on each other are negligible are called ideal solutions (or ideal mixtures). The ideal-gas mixture is just one category of ideal solutions. For ideal solutions, the enthalpy change and the volume change due to mixing are zero, but the entropy change is not. The chemical potential of a component of an ideal mixture is independent of the identity of the other constituents of the mixture. The chemical potential of a component in an ideal mixture is equal to the Gibbs function of the pure component.

13-81 Brackish water is used to produce fresh water. The minimum power input and the minimum height the brackish water must be raised by a pump for reverse osmosis are to be determined.

Assumptions 1 The brackish water is an ideal solution since it is dilute. 2 The total dissolved solids in water can be treated as table salt (NaCl). 3 The environment temperature is also 12°C.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ kg/kmol}$ and $M_s = 58.44 \text{ kg/kmol}$. The gas constant of pure water is $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The density of fresh water is 1000 kg/m^3 .

Analysis First we determine the mole fraction of pure water in brackish water using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.00078$ and $mf_w = 1 - mf_s = 0.99922$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.00078}{58.44} + \frac{0.99922}{18.0}} = 18.01 \text{ kg/kmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.99922) \frac{18.01 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.99976$$

The minimum work input required to produce 1 kg of freshwater from brackish water is

$$w_{\min, \text{in}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(285.15 \text{ K}) \ln(1/0.99976) = 0.03159 \text{ kJ/kg} \text{ fresh water}$$

Therefore, 0.03159 kJ of work is needed to produce 1 kg of fresh water is mixed with seawater reversibly. Therefore, the required power input to produce fresh water at the specified rate is

$$\dot{W}_{\min, \text{in}} = \rho \dot{V} w_{\min, \text{in}} = (1000 \text{ kg/m}^3)(0.280 \text{ m}^3/\text{s})(0.03159 \text{ kJ/kg}) \left(\frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = \mathbf{8.85 \text{ kW}}$$

The minimum height to which the brackish water must be pumped is

$$\Delta z_{\min} = \frac{w_{\min, \text{in}}}{g} = \left(\frac{0.03159 \text{ kJ/kg}}{9.81 \text{ m/s}^2} \right) \left(\frac{1 \text{ kg.m/s}^2}{1 \text{ N}} \right) \left(\frac{1000 \text{ N.m}}{1 \text{ kJ}} \right) = \mathbf{3.22 \text{ m}}$$

13-82 A river is discharging into the ocean at a specified rate. The amount of power that can be generated is to be determined.

Assumptions 1 The seawater is an ideal solution since it is dilute. 2 The total dissolved solids in water can be treated as table salt (NaCl). 3 The environment temperature is also 15°C.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ kg/kmol}$ and $M_s = 58.44 \text{ kg/kmol}$. The gas constant of pure water is $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The density of river water is 1000 kg/m^3 .

Analysis First we determine the mole fraction of pure water in ocean water using Eqs. 13-4 and 13-5. Noting that $\text{mf}_s = 0.025$ and $\text{mf}_w = 1 - \text{mf}_s = 0.975$,

$$M_m = \frac{1}{\sum \frac{\text{mf}_i}{M_i}} = \frac{1}{\frac{\text{mf}_s}{M_s} + \frac{\text{mf}_w}{M_w}} = \frac{1}{\frac{0.025}{58.44} + \frac{0.975}{18.0}} = 18.32 \text{ kg/kmol}$$

$$y_i = \text{mf}_i \frac{M_m}{M_i} \rightarrow y_w = \text{mf}_w \frac{M_m}{M_w} = (0.975) \frac{18.32 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.9922$$

The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is

$$w_{\max, \text{out}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(288.15 \text{ K}) \ln(1/0.9922) = 1.046 \text{ kJ/kg fresh water}$$

Therefore, 1.046 kJ of work can be produced as 1 kg of fresh water is mixed with seawater reversibly. Therefore, the power that can be generated as a river with a flow rate of $400,000 \text{ m}^3/\text{s}$ mixes reversibly with seawater is

$$\dot{W}_{\max, \text{out}} = \rho \dot{V} w_{\max, \text{out}} = (1000 \text{ kg/m}^3)(1.5 \times 10^5 \text{ m}^3/\text{s})(1.046 \text{ kJ/kg}) \left(\frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = \mathbf{157 \times 10^6 \text{ kW}}$$

Discussion This is more power than produced by all nuclear power plants (112 of them) in the U.S., which shows the tremendous amount of power potential wasted as the rivers discharge into the seas.

- 13-83** Problem 13-82 is reconsidered. The effect of the salinity of the ocean on the maximum power generated is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Given"

$$V_{\text{dot}}=150000 \text{ [m}^3/\text{s}]$$

"salinity=2.5"

$$T=(15+273.15) \text{ [K]}$$

"Properties"

$$M_w=18 \text{ [kg/kmol]} \text{ "molarmass(H}_2\text{O)"}$$

$$M_s=58.44 \text{ [kg/kmol]} \text{ "molar mass of salt"}$$

$$R_w=0.4615 \text{ [kJ/kg-K]} \text{ "gas constant of water"}$$

$$\rho=1000 \text{ [kg/m}^3]$$

"Analysis"

$$\text{mass}_w=100-\text{salinity}$$

$$mf_s=\text{salinity}/100$$

$$mf_w=\text{mass}_w/100$$

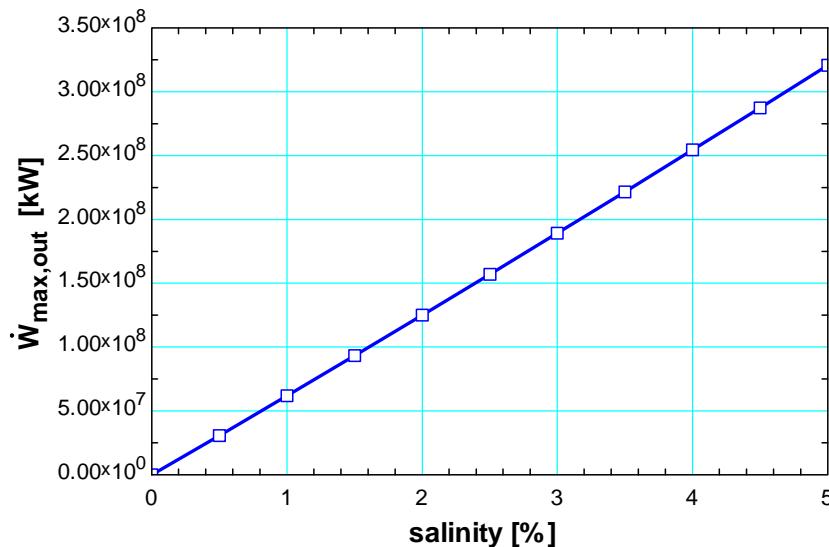

$$M_m=1/(mf_s/M_s+mf_w/M_w)$$

$$y_w=mf_w \cdot M_m/M_w$$

$$w_{\text{max,out}}=R_w \cdot T \cdot \ln(1/y_w)$$

$$W_{\text{dot,max,out}}=\rho \cdot V_{\text{dot}} \cdot w_{\text{max,out}}$$

Salinity [%]	$W_{\text{max,out}} [\text{kW}]$
0	0
0.5	3.085E+07
1	6.196E+07
1.5	9.334E+07
2	1.249E+08
2.5	1.569E+08
3	1.891E+08
3.5	2.216E+08
4	2.544E+08
4.5	2.874E+08
5	3.208E+08

13-84E Brackish water is used to produce fresh water. The mole fractions, the minimum work inputs required to separate 1 lbm of brackish water and to obtain 1 lbm of fresh water are to be determined.

Assumptions 1 The brackish water is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is equal to the water temperature.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ lbm/lbmol}$ and $M_s = 58.44 \text{ lbm/lbmol}$. The gas constant of pure water is $R_w = 0.1102 \text{ Btu/lbm\cdot R}$ (Table A-1E).

Analysis (a) First we determine the mole fraction of pure water in brackish water using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.0012$ and $mf_w = 1 - mf_s = 0.9988$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.0012}{58.44} + \frac{0.9988}{18.0}} = 18.015 \text{ lbm/lbmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.9988) \frac{18.015 \text{ lbm/lbmol}}{18.0 \text{ lbm/lbmol}} = \mathbf{0.99963}$$

$$y_s = 1 - y_w = 1 - 0.99963 = \mathbf{0.00037}$$

(b) The minimum work input required to separate 1 lbmol of brackish water is

$$\begin{aligned} w_{\min, \text{in}} &= -R_w T_0 (y_w \ln y_w + y_s \ln y_s) \\ &= -(0.1102 \text{ Btu/lbmol.R})(525 \text{ R})[0.99963 \ln(0.99963) + 0.00037 \ln(0.00037)] \\ &= \mathbf{-0.191 \text{ Btu/lbm}} \text{ brackish water} \end{aligned}$$

(c) The minimum work input required to produce 1 lbm of freshwater from brackish water is

$$w_{\min, \text{in}} = R_w T_0 \ln(1/y_w) = (0.1102 \text{ Btu/lbm\cdot R})(525 \text{ R}) \ln(1/0.99963) = \mathbf{0.0214 \text{ Btu/lbm fresh water}}$$

Discussion Note that it takes about 9 times work to separate 1 lbm of brackish water into pure water and salt compared to producing 1 lbm of fresh water from a large body of brackish water.

13-85 A desalination plant produces fresh water from seawater. The second law efficiency of the plant is to be determined.

Assumptions 1 The seawater is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is equal to the seawater temperature.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ kg/kmol}$ and $M_s = 58.44 \text{ kg/kmol}$. The gas constant of pure water is $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The density of river water is 1000 kg/m^3 .

Analysis First we determine the mole fraction of pure water in seawater using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.032$ and $mf_w = 1 - mf_s = 0.968$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.032}{58.44} + \frac{0.968}{18.0}} = 18.41 \text{ kg/kmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.968) \frac{18.41 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.9900$$

The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is

$$w_{\max, \text{out}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(283.15 \text{ K}) \ln(1/0.990) = 1.313 \text{ kJ/kg}$$

The power that can be generated as $1.4 \text{ m}^3/\text{s}$ fresh water mixes reversibly with seawater is

$$\dot{W}_{\max, \text{out}} = \rho \dot{V} w_{\max, \text{out}} = (1000 \text{ kg/m}^3)(1.4 \text{ m}^3/\text{s})(1.313 \text{ kJ/kg}) \left(\frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = 1.84 \text{ kW}$$

Then the second law efficiency of the plant becomes

$$\eta_{II} = \frac{\dot{W}_{\min, \text{in}}}{\dot{W}_{\text{in}}} = \frac{1.83 \text{ MW}}{8.5 \text{ MW}} = 0.216 = 21.6\%$$

13-86 The power consumption and the second law efficiency of a desalination plant are given. The power that can be produced if the fresh water produced is mixed with the seawater reversibly is to be determined.

Assumptions 1 This is a steady-flow process. **2** The kinetic and potential energy changes are negligible.

Analysis From the definition of the second law efficiency

$$\eta_{II} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_{\text{actual}}} \rightarrow 0.25 = \frac{\dot{W}_{\text{rev}}}{11,500 \text{ kW}} \rightarrow \dot{W}_{\text{rev}} = 2875 \text{ kW}$$

which is the maximum power that can be generated.

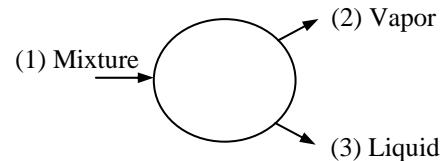

13-87E It is to be determined if it is possible for an adiabatic liquid-vapor separator to separate wet steam at 100 psia and 90 percent quality, so that the pressure of the outlet streams is greater than 100 psia.

Analysis Because the separator divides the inlet stream into the liquid and vapor portions,

$$\begin{aligned}\dot{m}_2 &= x\dot{m}_1 = 0.9\dot{m}_1 \\ \dot{m}_3 &= (1-x)\dot{m}_1 = 0.1\dot{m}_1\end{aligned}$$

According to the water property tables at 100 psia (Table A-5E),

$$s_1 = s_f + xs_{fg} = 0.47427 + 0.9 \times 1.12888 = 1.4903 \text{ Btu/lbm}\cdot\text{R}$$

When the increase in entropy principle is adapted to this system, it becomes

$$\begin{aligned}\dot{m}_2 s_2 + \dot{m}_3 s_3 &\geq \dot{m}_1 s_1 \\ x\dot{m}_1 s_2 + (1-x)\dot{m}_1 s_3 &\geq \dot{m}_1 s_1 \\ 0.9s_2 + 0.1s_3 &\geq s_1 \\ &\geq 1.4903 \text{ Btu/lbm}\cdot\text{R}\end{aligned}$$

To test this hypothesis, let's assume the outlet pressures are 110 psia. Then,

$$\begin{aligned}s_2 &= s_g = 1.5954 \text{ Btu/lbm}\cdot\text{R} \\ s_3 &= s_f = 0.48341 \text{ Btu/lbm}\cdot\text{R}\end{aligned}$$

The left-hand side of the above equation is

$$0.9s_2 + 0.1s_3 = 0.9 \times 1.5954 + 0.1 \times 0.48341 = 1.4842 \text{ Btu/lbm}\cdot\text{R}$$

which is less than the minimum possible specific entropy. Hence, the outlet pressure cannot be 110 psia. Inspection of the water table in light of above equation proves that the pressure at the separator outlet cannot be greater than that at the inlet.

Review Problems

13-88 Using Dalton's law, it is to be shown that $Z_m = \sum_{i=1}^k y_i Z_i$ for a real-gas mixture.

Analysis Using the compressibility factor, the pressure of a component of a real-gas mixture and of the pressure of the gas mixture can be expressed as

$$P_i = \frac{Z_i N_i R_u T_m}{V_m} \quad \text{and} \quad P_m = \frac{Z_m N_m R_u T_m}{V_m}$$

Dalton's law can be expressed as $P_m = \sum P_i(T_m, V_m)$. Substituting,

$$\frac{Z_m N_m R_u T_m}{V_m} = \sum \frac{Z_i N_i R_u T_m}{V_m}$$

Simplifying,

$$Z_m N_m = \sum Z_i N_i$$

Dividing by N_m ,

$$Z_m = \sum y_i Z_i$$

where Z_i is determined at the mixture temperature and volume.

13-89 The volume fractions of components of a gas mixture are given. The mole fractions, the mass fractions, the partial pressures, the mixture molar mass, apparent gas constant, and constant-pressure specific heat are to be determined and compared to the values in Table A-2a.

Properties The molar masses of N₂, O₂ and Ar are 28.0, 32.0, and 40.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at 300 K are 1.039, 0.918, and 0.5203 kJ/kg·K, respectively (Table A-2a).

Analysis The volume fractions are equal to the mole fractions:

$$y_{N_2} = \mathbf{0.78}, \quad y_{O_2} = \mathbf{0.21}, \quad y_{Ar} = \mathbf{0.01}$$

The volume fractions are equal to the pressure fractions. The partial pressures are then

$$P_{N_2} = y_{N_2} P_{\text{total}} = (0.78)(100 \text{ kPa}) = \mathbf{78 \text{ kPa}}$$

$$P_{O_2} = y_{O_2} P_{\text{total}} = (0.21)(100 \text{ kPa}) = \mathbf{21 \text{ kPa}}$$

$$P_{Ar} = y_{Ar} P_{\text{total}} = (0.01)(100 \text{ kPa}) = \mathbf{1 \text{ kPa}}$$

78% N₂
21% O₂
1% Ar
(by volume)

We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$m_{N_2} = N_{N_2} M_{N_2} = (78 \text{ kmol})(28 \text{ kg/kmol}) = 2184 \text{ kg}$$

$$m_{O_2} = N_{O_2} M_{O_2} = (21 \text{ kmol})(32 \text{ kg/kmol}) = 672 \text{ kg}$$

$$m_{Ar} = N_{Ar} M_{Ar} = (1 \text{ kmol})(40 \text{ kg/kmol}) = 40 \text{ kg}$$

The total mass is

$$m_m = m_{N_2} + m_{O_2} + m_{Ar} = 2184 + 672 + 40 = 2896 \text{ kg}$$

Then the mass fractions are

$$mf_{N_2} = \frac{m_{N_2}}{m_m} = \frac{2184 \text{ kg}}{2896 \text{ kg}} = \mathbf{0.7541}$$

$$mf_{O_2} = \frac{m_{O_2}}{m_m} = \frac{672 \text{ kg}}{2896 \text{ kg}} = \mathbf{0.2320}$$

$$mf_{Ar} = \frac{m_{Ar}}{m_m} = \frac{40 \text{ kg}}{2896 \text{ kg}} = \mathbf{0.0138}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2896 \text{ kg}}{100 \text{ kmol}} = \mathbf{28.96 \text{ kg/kmol}}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{O_2} c_{p,O_2} + mf_{Ar} c_{p,Ar} \\ &= 0.7541 \times 1.039 + 0.2320 \times 0.918 + 0.0138 \times 0.5203 \\ &= \mathbf{1.004 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.96 \text{ kg/kmol}} = \mathbf{0.2871 \text{ kJ/kg} \cdot \text{K}}$$

This mixture closely correspond to the air, and the mixture properties determined (mixture molar mass, mixture gas constant and mixture specific heat) are practically the same as those listed for air in Tables A-1 and A-2a.

13-90 The mole numbers of combustion gases are given. The partial pressure of water vapor and the condensation temperature of water vapor are to be determined.

Properties The molar masses of CO₂, H₂O, O₂ and N₂ are 44.0, 18.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1).

Analysis The total mole of the mixture and the mole fraction of water vapor are

$$N_{\text{total}} = 8 + 9 + 12.5 + 94 = 123.5 \text{ kmol}$$

$$\gamma_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{9}{123.5} = 0.07287$$

Noting that molar fraction is equal to pressure fraction, the partial pressure of water vapor is

$$P_{\text{H}_2\text{O}} = \gamma_{\text{H}_2\text{O}} P_{\text{total}} = (0.07287)(100 \text{ kPa}) = \mathbf{7.29 \text{ kPa}}$$

The temperature at which the condensation starts is the saturation temperature of water at this pressure. This is called the dew-point temperature. Then,

$$T_{\text{cond}} = T_{\text{sat@7.29 kPa}} = \mathbf{39.7^\circ\text{C}} \quad (\text{Table A-5})$$

Water vapor in the combustion gases will start to condense when the temperature of the combustion gases drop to 39.7°C.

13-91 The masses of gases forming a mixture at a specified pressure and temperature are given. The mass of the gas mixture is to be determined using four methods.

Properties The molar masses of O₂, CO₂, and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1).

Analysis (a) The given total mass of the mixture is

$$m_m = m_{O_2} + m_{CO_2} + m_{He} = 0.1 + 1 + 0.5 = 1.6 \text{ kg}$$

The mole numbers of each component are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{0.1 \text{ kg}}{32 \text{ kg/kmol}} = 0.003125 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.02273 \text{ kmol}$$

$$N_{He} = \frac{m_{He}}{M_{He}} = \frac{0.5 \text{ kg}}{4 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

0.1 kg O ₂
1 kg CO ₂
0.5 kg He

The mole number of the mixture is

$$N_m = N_{O_2} + N_{CO_2} + N_{He} = 0.003125 + 0.02273 + 0.125 = 0.1509 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{1.6 \text{ kg}}{0.1509 \text{ kmol}} = 10.61 \text{ kg/kmol}$$

The mass of this mixture in a 0.3 m³ tank is

$$m = \frac{M_m P V}{R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = 22.87 \text{ kg}$$

(b) To use the Amagat's law for this real gas mixture, we first need the mole fractions and the Z of each component at the mixture temperature and pressure.

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.003125 \text{ kmol}}{0.1509 \text{ kmol}} = 0.02071$$

$$y_{CO_2} = \frac{N_{CO_2}}{N_m} = \frac{0.02273 \text{ kmol}}{0.1509 \text{ kmol}} = 0.1506$$

$$y_{He} = \frac{N_{He}}{N_m} = \frac{0.125 \text{ kmol}}{0.1509 \text{ kmol}} = 0.8284$$

$$\left. \begin{aligned} T_{R,O_2} &= \frac{T_m}{T_{cr,O_2}} = \frac{293 \text{ K}}{154.8 \text{ K}} = 1.893 \\ P_{R,O_2} &= \frac{P_m}{P_{cr,O_2}} = \frac{17.5 \text{ MPa}}{5.08 \text{ MPa}} = 3.445 \end{aligned} \right\} Z_{O_2} = 0.93 \quad (\text{Fig. A-15})$$

$$\left. \begin{aligned} T_{R,CO_2} &= \frac{T_m}{T_{cr,CO_2}} = \frac{293 \text{ K}}{304.2 \text{ K}} = 0.963 \\ P_{R,CO_2} &= \frac{P_m}{P_{cr,CO_2}} = \frac{17.5 \text{ MPa}}{7.39 \text{ MPa}} = 2.368 \end{aligned} \right\} Z_{CO_2} = 0.33 \quad (\text{Fig. A-15})$$

$$\left. \begin{aligned} T_{R,He} &= \frac{T_m}{T_{cr,He}} = \frac{293 \text{ K}}{5.3 \text{ K}} = 55.3 \\ P_{R,He} &= \frac{P_m}{P_{cr,He}} = \frac{17.5 \text{ MPa}}{0.23 \text{ MPa}} = 76.1 \end{aligned} \right\} Z_{He} = 1.04 \quad (\text{from EES})$$

Then,

$$\begin{aligned} Z_m &= \sum y_i Z_i = y_{\text{O}_2} Z_{\text{O}_2} + y_{\text{CO}_2} Z_{\text{CO}_2} + y_{\text{He}} Z_{\text{He}} \\ &= (0.02071)(0.93) + (0.1506)(0.33) + (0.8284)(1.04) = 0.9305 \end{aligned}$$

$$m = \frac{M_m P V}{Z_m R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(0.9305)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{24.57 \text{ kg}}$$

(c) To use Dalton's law with compressibility factors:

$$\left. \begin{aligned} T_{R,\text{O}_2} &= 1.893 \\ \nu_{R,\text{O}_2} &= \frac{\nu_m/m_{\text{O}_2}}{R_{\text{O}_2} T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} = \frac{(0.3 \text{ m}^3)/(22.87 \times 0.1/1.6 \text{ kg})}{(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(154.8 \text{ K})/(5080 \text{ kPa})} = 26.5 \end{aligned} \right\} Z_{\text{O}_2} = 1.0$$

$$\left. \begin{aligned} T_{R,\text{CO}_2} &= 0.963 \\ \nu_{R,\text{CO}_2} &= \frac{\nu_m/m_{\text{CO}_2}}{R_{\text{CO}_2} T_{\text{cr},\text{CO}_2} / P_{\text{cr},\text{CO}_2}} = \frac{(0.3 \text{ m}^3)/(22.87 \times 1.0/1.6 \text{ kg})}{(0.1889 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(304.2 \text{ K})/(7390 \text{ kPa})} = 2.70 \end{aligned} \right\} Z_{\text{CO}_2} = 0.86$$

$$\left. \begin{aligned} T_{R,\text{He}} &= 55.3 \\ \nu_{R,\text{He}} &= \frac{\nu_m/m_{\text{He}}}{R_{\text{He}} T_{\text{cr},\text{He}} / P_{\text{cr},\text{He}}} = \frac{(0.3 \text{ m}^3)/(22.87 \times 0.5/1.6 \text{ kg})}{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(5.3 \text{ K})/(230 \text{ kPa})} = 0.88 \end{aligned} \right\} Z_{\text{He}} = 1.0$$

Note that we used $m = 22.87 \text{ kg}$ in above calculations, the value obtained by ideal gas behavior. The solution normally requires iteration until the assumed and calculated mass values match. The mass of the component gas is obtained by multiplying the mass of the mixture by its mass fraction. Then,

$$\begin{aligned} Z_m &= \sum y_i Z_i = y_{\text{O}_2} Z_{\text{O}_2} + y_{\text{CO}_2} Z_{\text{CO}_2} + y_{\text{He}} Z_{\text{He}} \\ &= (0.02071)(1.0) + (0.1506)(0.86) + (0.8284)(1.0) = 0.9786 \end{aligned}$$

$$m = \frac{M_m P V}{Z_m R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(0.9786)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{23.37 \text{ kg}}$$

This mass is sufficiently close to the mass value 22.87 kg. Therefore, there is no need to repeat the calculations at this calculated mass.

(d) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of O₂, CO₂ and He.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{O}_2} T_{\text{cr},\text{O}_2} + y_{\text{CO}_2} T_{\text{cr},\text{CO}_2} + y_{\text{He}} T_{\text{cr},\text{He}} \\ &= (0.02071)(154.8 \text{ K}) + (0.1506)(304.2 \text{ K}) + (0.8284)(5.3 \text{ K}) = 53.41 \text{ K} \\ P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{O}_2} P_{\text{cr},\text{O}_2} + y_{\text{CO}_2} P_{\text{cr},\text{CO}_2} + y_{\text{He}} P_{\text{cr},\text{He}} \\ &= (0.02071)(5.08 \text{ MPa}) + (0.1506)(7.39 \text{ MPa}) + (0.8284)(0.23 \text{ MPa}) = 1.409 \text{ MPa} \end{aligned}$$

Then,

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{\text{cr},m}} = \frac{293 \text{ K}}{53.41 \text{ K}} = 5.486 \\ P_R &= \frac{P_m}{P'_{\text{cr},m}} = \frac{17.5 \text{ MPa}}{1.409 \text{ MPa}} = 12.42 \end{aligned} \right\} Z_m = 1.194 \quad (\text{from EES})$$

$$m = \frac{M_m P V}{Z_m R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(1.194)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{19.15 \text{ kg}}$$

13-92 A mixture of carbon dioxide and nitrogen flows through a converging nozzle. The required make up of the mixture on a mass basis is to be determined.

Assumptions Under specified conditions CO₂ and N₂ can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of CO₂ and N₂ are 44.0 and 28.0 kg/kmol, respectively (Table A-1). The specific heat ratios of CO₂ and N₂ at 500 K are $k_{\text{CO}_2} = 1.229$ and $k_{\text{N}_2} = 1.391$ (Table A-2).

Analysis The molar mass of the mixture is determined from

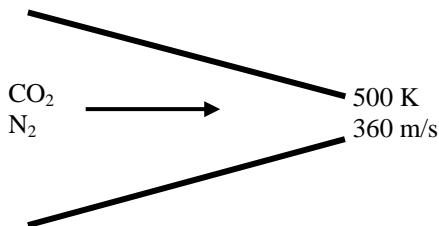

$$M_m = y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{N}_2} M_{\text{N}_2}$$

The molar fractions are related to each other by

$$y_{\text{CO}_2} + y_{\text{N}_2} = 1$$

The gas constant of the mixture is given by

$$R_m = \frac{R_u}{M_m}$$

The specific heat ratio of the mixture is expressed as

$$k = mf_{\text{CO}_2} k_{\text{CO}_2} + mf_{\text{N}_2} k_{\text{N}_2}$$

The mass fractions are

$$mf_{\text{CO}_2} = y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m}$$

$$mf_{\text{N}_2} = y_{\text{N}_2} \frac{M_{\text{N}_2}}{M_m}$$

The exit velocity equals the speed of sound at 500 K

$$V_{\text{exit}} = \sqrt{k R_m T \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

Substituting the given values and known properties and solving the above equations simultaneously using EES, we find

$$mf_{\text{CO}_2} = \mathbf{0.838}$$

$$mf_{\text{N}_2} = \mathbf{0.162}$$

13-93E A mixture of nitrogen and oxygen is expanded isothermally. The work produced is to be determined.

Assumptions 1 Nitrogen and oxygen are ideal gases. 2 The process is reversible.

Properties The mole numbers of nitrogen and oxygen are 28.0 and 32.0 lbm/lbmol, respectively (Table A-1E).

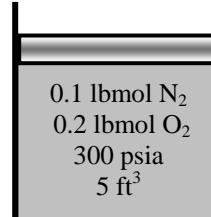

Analysis The mole fractions are

$$y_{N_2} = \frac{N_{N_2}}{N_{\text{total}}} = \frac{0.1 \text{ lbmol}}{0.3 \text{ lbmol}} = 0.3333$$

$$y_{O_2} = \frac{N_{O_2}}{N_{\text{total}}} = \frac{0.2 \text{ kmol}}{0.3 \text{ kmol}} = 0.6667$$

The gas constant for this mixture is then

$$\begin{aligned} R &= \frac{R_u}{y_{N_2} M_{N_2} + y_{O_2} M_{O_2}} \\ &= \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{(0.3333 \times 28 + 0.6667 \times 32) \text{ lbm/lbmol}} \\ &= 0.06475 \text{ Btu/lbm} \cdot \text{R} \\ &= (0.06475 \text{ Btu/lbm} \cdot \text{R}) \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) \\ &= 0.3499 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R} \end{aligned}$$

The mass of this mixture of gases is

$$m = N_{N_2} M_{N_2} + N_{O_2} M_{O_2} = 0.1 \times 28 + 0.2 \times 32 = 9.2 \text{ lbm}$$

The temperature of the mixture is

$$T_1 = \frac{P_1 V_1}{mR} = \frac{(300 \text{ psia})(5 \text{ ft}^3)}{(9.2 \text{ lbm})(0.3499 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})} = 466.0 \text{ R}$$

Noting that $Pv = RT$ for an ideal gas, the work done for this process is then

$$\begin{aligned} W_{\text{out}} &= m \int_1^2 P dV = mRT \int_1^2 \frac{dV}{V} = mRT \ln \frac{V_2}{V_1} \\ &= (9.2 \text{ lbm})(0.06475 \text{ Btu/lbm} \cdot \text{R})(466 \text{ R}) \ln \frac{10 \text{ ft}^3}{5 \text{ ft}^3} \\ &= \mathbf{192.4 \text{ Btu}} \end{aligned}$$

13-94 A mixture of nitrogen and carbon dioxide is compressed at constant temperature in a closed system. The work required is to be determined.

Assumptions 1 Nitrogen and carbon dioxide are ideal gases. 2 The process is reversible.

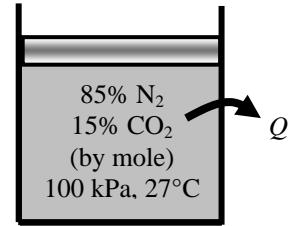

Properties The mole numbers of nitrogen and carbon dioxide are 28.0 and 44.0 kg/kmol, respectively (Table A-1).

Analysis The effective molecular weight of this mixture is

$$\begin{aligned} M &= y_{\text{N}_2} M_{\text{N}_2} + y_{\text{CO}_2} M_{\text{CO}_2} \\ &= (0.85)(28) + (0.15)(44) \\ &= 30.4 \text{ kg/kmol} \end{aligned}$$

The work done is determined from

$$\begin{aligned} w &= \int_1^2 P dV = RT \int_1^2 \frac{d\nu}{\nu} = RT \ln \frac{\nu_2}{\nu_1} = RT \ln \frac{P_2}{P_1} = \frac{R_u}{M} RT \ln \frac{P_2}{P_1} \\ &= \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{30.4 \text{ kg/kmol}} (300 \text{ K}) \ln \frac{500 \text{ kPa}}{100 \text{ kPa}} \\ &= \mathbf{132.0 \text{ kJ/kg}} \end{aligned}$$

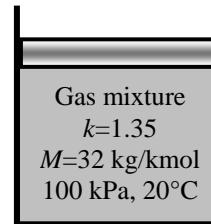

13-95 The specific heat ratio and an apparent molecular weight of a mixture of ideal gases are given. The work required to compress this mixture isentropically in a closed system is to be determined.

Analysis For an isentropic process of an ideal gas with constant specific heats, the work is expressed as

$$\begin{aligned} w_{\text{out}} &= \int_1^2 P d\nu = P_1 \nu_1^k \int_1^2 \nu^{-k} d\nu \\ &= \frac{P_1 \nu_1^k}{1-k} (\nu_2^{1-k} - \nu_1^{1-k}) = \frac{P_1 \nu_1^k}{1-k} \left[\left(\frac{\nu_2}{\nu_1} \right)^{1-k} - 1 \right] \end{aligned}$$

since $P_1 \nu_1^k = P \nu^k$ for an isentropic process. Also,

$$\begin{aligned} P_1 \nu_1 &= RT_1 \\ (\nu_2 / \nu_1)^k &= P_1 / P_2 \end{aligned}$$

Substituting, we obtain

$$\begin{aligned} w_{\text{out}} &= \frac{R_u T_1}{M(1-k)} \left[\left(\frac{P_2}{P_1} \right)^{(k-1)/k} - 1 \right] \\ &= \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(293 \text{ K})}{(32 \text{ kg/kmol})(1-1.35)} \left[\left(\frac{1000 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.35-1)/1.35} - 1 \right] \\ &= \mathbf{-177.6 \text{ kJ/kg}} \end{aligned}$$

The negative sign shows that the work is done on the system.

13-96 A mixture of gases is placed in a spring-loaded piston-cylinder device. The device is now heated until the pressure rises to a specified value. The total work and heat transfer for this process are to be determined.

Properties The molar masses of Ne, O₂, and N₂ are 20.18, 32.0, 28.0 kg/kmol, respectively and the gas constants are 0.4119, 0.2598, and 0.2968 kJ/kg·K, respectively (Table A-1). The constant-volume specific heats are 0.6179, 0.658, and 0.743 kJ/kg·K, respectively (Table A-2a).

Analysis The total pressure is 200 kPa and the partial pressures are

$$P_{\text{Ne}} = y_{\text{Ne}} P_m = (0.25)(200 \text{ kPa}) = 50 \text{ kPa}$$

$$P_{\text{O}_2} = y_{\text{O}_2} P_m = (0.50)(200 \text{ kPa}) = 100 \text{ kPa}$$

$$P_{\text{N}_2} = y_{\text{N}_2} P_m = (0.25)(200 \text{ kPa}) = 50 \text{ kPa}$$

The mass of each constituent for a volume of 0.1 m³ and a temperature of 10°C are

$$m_{\text{Ne}} = \frac{P_{\text{Ne}} V_m}{R_{\text{Ne}} T} = \frac{(50 \text{ kPa})(0.1 \text{ m}^3)}{(0.4119 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.04289 \text{ kg}$$

$$m_{\text{O}_2} = \frac{P_{\text{O}_2} V_m}{R_{\text{O}_2} T} = \frac{(100 \text{ kPa})(0.1 \text{ m}^3)}{(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.1360 \text{ kg}$$

$$m_{\text{N}_2} = \frac{P_{\text{N}_2} V_m}{R_{\text{N}_2} T} = \frac{(50 \text{ kPa})(0.1 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.05953 \text{ kg}$$

$$m_{\text{total}} = 0.04289 + 0.1360 + 0.05953 = 0.2384 \text{ kg}$$

The mass fractions are

$$\text{mf}_{\text{Ne}} = \frac{m_{\text{Ne}}}{m_m} = \frac{0.04289 \text{ kg}}{0.2384 \text{ kg}} = 0.1799$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{0.1360 \text{ kg}}{0.2384 \text{ kg}} = 0.5705$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{0.05953 \text{ kg}}{0.2384 \text{ kg}} = 0.2497$$

The constant-volume specific heat of the mixture is determined from

$$\begin{aligned} c_v &= \text{mf}_{\text{Ne}} c_{v,\text{Ne}} + \text{mf}_{\text{O}_2} c_{v,\text{O}_2} + \text{mf}_{\text{N}_2} c_{v,\text{N}_2} \\ &= 0.1799 \times 0.6179 + 0.5705 \times 0.658 + 0.2497 \times 0.743 = 0.672 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The moles are

$$N_{\text{Ne}} = \frac{m_{\text{Ne}}}{M_{\text{Ne}}} = \frac{0.04289 \text{ kg}}{20.18 \text{ kg/kmol}} = 0.002126 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.1360 \text{ kg}}{32 \text{ kg/kmol}} = 0.00425 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{0.05953 \text{ kg}}{28 \text{ kg/kmol}} = 0.002126 \text{ kmol}$$

$$N_m = N_{\text{Ne}} + N_{\text{O}_2} + N_{\text{N}_2} = 0.008502 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{0.2384 \text{ kg}}{0.008502 \text{ kmol}} = 28.04 \text{ kg/kmol}$$

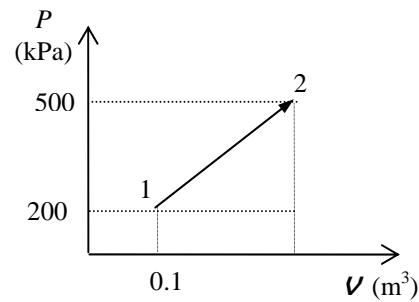

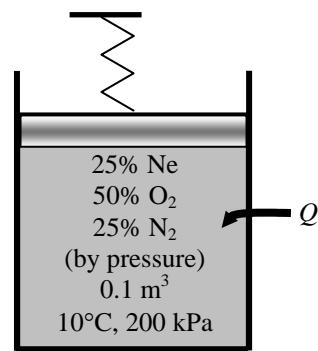

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.04 \text{ kg/kmol}} = 0.2964 \text{ kJ/kg} \cdot \text{K}$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2964 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.2384 \text{ kg}$$

Noting that the pressure changes linearly with volume, the final volume is determined by linear interpolation to be

$$\frac{500 - 200}{1000 - 200} = \frac{V_2 - 0.1}{1.0 - 0.1} \longrightarrow V_2 = 0.4375 \text{ m}^3$$

The final temperature is

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(500 \text{ kPa})(0.4375 \text{ m}^3)}{(0.2384 \text{ kg})(0.2964 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 3096 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(500 + 200) \text{ kPa}}{2} (0.4375 - 0.1) \text{ m}^3 = 118 \text{ kJ}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v(T_2 - T_1) = 118 + (0.2384 \text{ kg})(0.672 \text{ kJ/kg} \cdot \text{K})(3096 - 283) \text{ K} = 569 \text{ kJ}$$

13-97 A spring-loaded piston-cylinder device is filled with a mixture of nitrogen and carbon dioxide whose mass fractions are given. The gas is heated until the volume has doubled. The total work and heat transfer for this process are to be determined.

Properties The molar masses of N₂ and CO₂ are 28.0 and 44.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at room temperature are 0.743 and 0.657 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{55 \text{ kg}}{28 \text{ kg/kmol}} = 1.964 \text{ kmol}$$

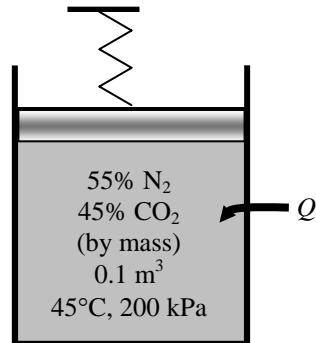

$$N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{45 \text{ kg}}{44 \text{ kg/kmol}} = 1.023 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{\text{N}_2} + N_{\text{CO}_2} = 1.964 + 1.023 = 2.987 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{2.987 \text{ kmol}} = 33.48 \text{ kg/kmol}$$

The constant-volume specific heat of the mixture is determined from

$$c_v = m f_{\text{N}_2} c_{v,\text{N}_2} + m f_{\text{CO}_2} c_{v,\text{CO}_2} = 0.55 \times 0.743 + 0.45 \times 0.657 = 0.7043 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{33.48 \text{ kg/kmol}} = 0.2483 \text{ kJ/kg} \cdot \text{K}$$

Noting that the pressure changes linearly with volume, the initial volume is determined by linear interpolation using the data of the previous problem to be

$$\frac{200 - 200}{1000 - 200} = \frac{V_1 - 0.1}{1.0 - 0.1} \longrightarrow V_1 = 0.1 \text{ m}^3$$

The final volume is

$$V_2 = 2V_1 = 2(0.1 \text{ m}^3) = 0.2 \text{ m}^3$$

The final pressure is similarly determined by linear interpolation using the data of the previous problem to be

$$\frac{P_2 - 200}{1000 - 200} = \frac{0.2 - 0.1}{1.0 - 0.1} \longrightarrow P_2 = 288.9 \text{ kPa}$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(318 \text{ K})} = 0.2533 \text{ kg}$$

The final temperature is

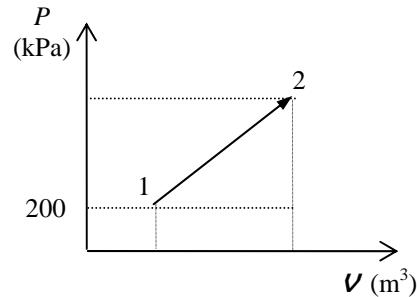

$$T_2 = \frac{P_2 V_2}{m R} = \frac{(288.9 \text{ kPa})(0.2 \text{ m}^3)}{(0.2533 \text{ kg})(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 918.7 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(200 + 288.9) \text{ kPa}}{2} (0.2 - 0.1) \text{ m}^3 = 24.4 \text{ kJ}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v(T_2 - T_1) = 24.4 + (0.2533 \text{ kg})(0.7043 \text{ kJ/kg} \cdot \text{K})(918.7 - 318) \text{ K} = 132 \text{ kJ}$$

13-98 A spring-loaded piston-cylinder device is filled with a mixture of nitrogen and carbon dioxide whose mass fractions are given. The gas is heated until the pressure has tripled. The total work and heat transfer for this process are to be determined.

Properties The molar masses of N₂ and CO₂ are 28.0 and 44.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at room temperature are 0.743 and 0.657 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{55 \text{ kg}}{28 \text{ kg/kmol}} = 1.964 \text{ kmol}$$

$$N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{45 \text{ kg}}{44 \text{ kg/kmol}} = 1.023 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{\text{N}_2} + N_{\text{CO}_2} = 1.964 + 1.023 = 2.987 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{2.987 \text{ kmol}} = 33.48 \text{ kg/kmol}$$

The constant-volume specific heat of the mixture is determined from

$$c_v = m f_{\text{N}_2} c_{v,\text{N}_2} + m f_{\text{CO}_2} c_{v,\text{CO}_2} = 0.55 \times 0.743 + 0.45 \times 0.657 = 0.7043 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{33.48 \text{ kg/kmol}} = 0.2483 \text{ kJ/kg} \cdot \text{K}$$

Noting that the pressure changes linearly with volume, the initial volume is determined by linear interpolation using the data of the previous problem to be

$$\frac{200 - 200}{1000 - 200} = \frac{V_1 - 0.1}{1.0 - 0.1} \longrightarrow V_1 = 0.1 \text{ m}^3$$

The final pressure is

$$P_2 = 3P_1 = 3(200 \text{ kPa}) = 600 \text{ kPa}$$

The final volume is similarly determined by linear interpolation using the data of the previous problem to be

$$\frac{600 - 200}{1000 - 200} = \frac{V_2 - 0.1}{1.0 - 0.1} \longrightarrow V_2 = 0.55 \text{ m}^3$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(318 \text{ K})} = 0.2533 \text{ kg}$$

The final temperature is

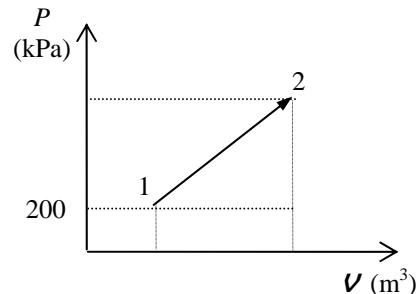

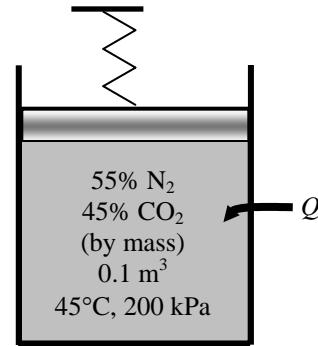

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(600 \text{ kPa})(0.55 \text{ m}^3)}{(0.2533 \text{ kg})(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 5247 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(200 + 600) \text{ kPa}}{2} (0.55 - 0.1) \text{ m}^3 = 180 \text{ kJ}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v(T_2 - T_1) = 180 + (0.2533 \text{ kg})(0.7043 \text{ kJ/kg} \cdot \text{K})(5247 - 318) \text{ K} = 1059 \text{ kJ}$$

13-99 The masses, pressures, and temperatures of the constituents of a gas mixture in a tank are given. Heat is transferred to the tank. The final pressure of the mixture and the heat transfer are to be determined.

Assumptions He is an ideal gas and O₂ is a nonideal gas.

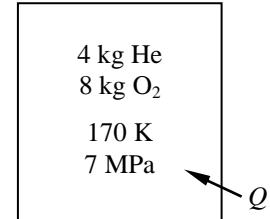

Properties The molar masses of He and O₂ are 4.0 and 32.0 kg/kmol. (Table A-1)

Analysis (a) The number of moles of each gas is

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{4 \text{ kg}}{4.0 \text{ kg/kmol}} = 1 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{8 \text{ kg}}{32 \text{ kg/kmol}} = 0.25 \text{ kmol}$$

$$N_m = N_{\text{He}} + N_{\text{O}_2} = 1 \text{ kmol} + 0.25 \text{ kmol} = 1.25 \text{ kmol}$$

Then the partial volume of each gas and the volume of the tank are

He:

$$\nu_{\text{He}} = \frac{N_{\text{He}} R_u T_1}{P_{m,1}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(170 \text{ K})}{7000 \text{ kPa}} = 0.202 \text{ m}^3$$

O₂:

$$\left. \begin{aligned} P_{R_1} &= \frac{P_{m,1}}{P_{\text{cr},\text{O}_2}} = \frac{7}{5.08} = 1.38 \\ T_{R_1} &= \frac{T_1}{T_{\text{cr},\text{O}_2}} = \frac{170}{154.8} = 1.10 \end{aligned} \right\} Z_1 = 0.53 \quad (\text{Fig. A-15})$$

$$\nu_{\text{O}_2} = \frac{Z N_{\text{O}_2} R_u T_1}{P_{m,1}} = \frac{(0.53)(0.25 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(170 \text{ K})}{7000 \text{ kPa}} = 0.027 \text{ m}^3$$

$$\nu_{\text{tank}} = \nu_{\text{He}} + \nu_{\text{O}_2} = 0.202 \text{ m}^3 + 0.027 \text{ m}^3 = 0.229 \text{ m}^3$$

The partial pressure of each gas and the total final pressure is

He:

$$P_{\text{He},2} = \frac{N_{\text{He}} R_u T_2}{\nu_{\text{tank}}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(220 \text{ K})}{0.229 \text{ m}^3} = 7987 \text{ kPa}$$

O₂:

$$\left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{\text{cr},\text{O}_2}} = \frac{220}{154.8} = 1.42 \\ \bar{\nu}_{\text{O}_2} &= \frac{\nu_{\text{O}_2}}{R_u T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} = \frac{\nu_m / N_{\text{O}_2}}{R_u T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} \\ &= \frac{(0.229 \text{ m}^3)/(0.25 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(154.8 \text{ K})/(5080 \text{ kPa})} = 3.616 \end{aligned} \right\} P_R = 0.39 \quad (\text{Fig. A-15})$$

$$P_{\text{O}_2} = (P_R P_{\text{cr}})_{\text{O}_2} = (0.39)(5080 \text{ kPa}) = 1981 \text{ kPa} = 1.981 \text{ MPa}$$

$$P_{m,2} = P_{\text{He}} + P_{\text{O}_2} = 7.987 \text{ MPa} + 1.981 \text{ MPa} = \mathbf{9.97 \text{ MPa}}$$

(b) We take both gases as the system. No work or mass crosses the system boundary, therefore this is a closed system with no work interactions. Then the energy balance for this closed system reduces to

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ Q_{\text{in}} &= \Delta U = \Delta U_{\text{He}} + \Delta U_{\text{O}_2} \end{aligned}$$

He:

$$\Delta U_{\text{He}} = mc_v(T_m - T_1) = (4 \text{ kg})(3.1156 \text{ kJ/kg}\cdot\text{K})(220 - 170)\text{K} = 623.1 \text{ kJ}$$

O₂:

$$\left. \begin{array}{l} T_{R_1} = 1.10 \\ P_{R_1} = 1.38 \end{array} \right\} Z_{h_1} = 2.2$$

$$\left. \begin{array}{l} T_{R_2} = 1.42 \\ P_{R_2} = \frac{9.97}{5.08} = 1.963 \end{array} \right\} Z_{h_2} = 1.2 \quad (\text{Fig. A-29})$$

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= R_u T_{\text{cr}} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314 \text{ kJ/kmol}\cdot\text{K})(154.8 \text{ K})(2.2 - 1.2) + (6404 - 4949) \text{ kJ/kmol} \\ &= 2742 \text{ kJ/kmol} \end{aligned}$$

Also,

$$\begin{aligned} P_{\text{He},1} &= \frac{N_{\text{He}} R_u T_1}{V_{\text{tank}}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(170 \text{ K})}{0.229 \text{ m}^3} = 6,172 \text{ kPa} \\ P_{\text{O}_2,1} &= P_{m,1} - P_{\text{He},1} = 7000 \text{ kPa} - 6172 \text{ kPa} = 828 \text{ kPa} \end{aligned}$$

Thus,

$$\begin{aligned} \Delta U_{\text{O}_2} &= N_{\text{O}_2} (\bar{h}_2 - \bar{h}_1) - (P_2 V_2 - P_1 V_1) = N_{\text{O}_2} (\bar{h}_2 - \bar{h}_1) - (P_{\text{O}_2,2} - P_{\text{O}_2,1}) V_{\text{tank}} \\ &= (0.25 \text{ kmol})(2742 \text{ kJ/kmol}) - (1981 - 828)(0.229) \text{ kPa}\cdot\text{m}^3 \\ &= 421.5 \text{ kJ} \end{aligned}$$

Substituting,

$$Q_{\text{in}} = 623.1 \text{ kJ} + 421.5 \text{ kJ} = \mathbf{1045 \text{ kJ}}$$

13-100 A mixture of carbon dioxide and methane expands through a turbine. The power produced by the mixture is to be determined using ideal gas approximation and Kay's rule.

Assumptions The expansion process is reversible and adiabatic (isentropic).

Properties The molar masses of CO₂ and CH₄ are 44.0 and 16.0 kg/kmol and respectively. The critical properties are 304.2 K, 7390 kPa for CO₂ and 191.1 K and 4640 kPa for CH₄ (Table A-1). EES may use slightly different values.

Analysis The molar mass of the mixture is determined to be

$$M_m = y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{CH}_4} M_{\text{CH}_4} = (0.75)(44) + (0.25)(16) = 37.0 \text{ kg/kmol}$$

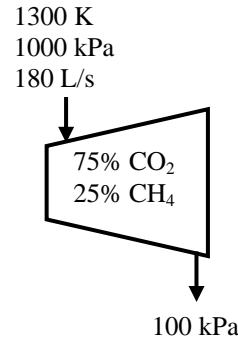

The gas constant is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol.K}}{37.0 \text{ kg/kmol}} = 0.2246 \text{ kJ/kg.K}$$

The mass fractions are

$$mf_{\text{CO}_2} = y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m} = (0.75) \frac{44 \text{ kg/kmol}}{37.0 \text{ kg/kmol}} = 0.8917$$

$$mf_{\text{CH}_4} = y_{\text{CH}_4} \frac{M_{\text{CH}_4}}{M_m} = (0.25) \frac{16 \text{ kg/kmol}}{37.0 \text{ kg/kmol}} = 0.1083$$

Ideal gas solution:

Using Dalton's law to find partial pressures, the entropies at the initial state are determined from EES to be:

$$T = 1300 \text{ K}, P = (0.75 \times 1000) = 750 \text{ kPa} \longrightarrow s_{\text{CO}_2,1} = 6.068 \text{ kJ/kg.K}$$

$$T = 1600 \text{ K}, P = (0.25 \times 1000) = 250 \text{ kPa} \longrightarrow s_{\text{CH}_4,1} = 16.22 \text{ kJ/kg.K}$$

The final state entropies cannot be determined at this point since the final temperature is not known. However, for an isentropic process, the entropy change is zero and the final temperature may be determined from

$$\begin{aligned} \Delta s_{\text{total}} &= mf_{\text{CO}_2} \Delta s_{\text{CO}_2} + mf_{\text{CH}_4} \Delta s_{\text{CH}_4} \\ 0 &= mf_{\text{CO}_2} (s_{\text{CO}_2,2} - s_{\text{CO}_2,1}) + mf_{\text{CH}_4} (s_{\text{CH}_4,2} - s_{\text{CH}_4,1}) \end{aligned}$$

The solution is obtained using EES to be

$$T_2 = 947.1 \text{ K}$$

The initial and final enthalpies and the changes in enthalpy are (from EES)

$$\begin{array}{ll} T_1 = 1300 \text{ K} \longrightarrow h_{\text{CO}_2,1} = -7803 \text{ kJ/kg} & T_2 = 947.1 \text{ K} \longrightarrow h_{\text{CO}_2,2} = -8248 \text{ kJ/kg} \\ h_{\text{CH}_4,1} = -831 \text{ kJ/kg} & h_{\text{CH}_4,2} = -2503 \text{ kJ/kg} \end{array}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$\dot{Q}_{\text{in}} - \dot{W}_{\text{out}} = \dot{m} \Delta h_m \longrightarrow \dot{W}_{\text{out}} = -\dot{m} \Delta h_m$$

where

$$\begin{aligned} \Delta h_m &= mf_{\text{CO}_2} (h_{\text{CO}_2,2} - h_{\text{CO}_2,1}) + mf_{\text{CH}_4} (h_{\text{CH}_4,2} - h_{\text{CH}_4,1}) \\ &= (0.8917)[(-8248) - (-7803)] + (0.1083)[(-2503) - (-831)] = -577.7 \text{ kJ/kg} \end{aligned}$$

The mass flow rate is

$$\dot{m} = \frac{P_1 \dot{V}_1}{RT_1} = \frac{(1000 \text{ kPa})(0.180 \text{ m}^3/\text{s})}{(0.2246 \text{ kJ/kg.K})(1300 \text{ K})} = 0.6165 \text{ kg/s}$$

$$\text{Substituting, } \dot{W}_{\text{out}} = \dot{m} \Delta h_m = -(0.6165)(-577.7 \text{ kJ/kg}) = \mathbf{356 \text{ kW}}$$

Kay's rule solution:

The critical temperature and pressure of the mixture is

$$T_{\text{cr}} = y_{\text{CO}_2} T_{\text{cr,CO}_2} + y_{\text{CH}_4} T_{\text{cr,CH}_4} = (0.75)(304.2 \text{ K}) + (0.25)(191.1 \text{ K}) = 276 \text{ K}$$

$$P_{\text{cr}} = y_{\text{CO}_2} P_{\text{cr,CO}_2} + y_{\text{CH}_4} P_{\text{cr,CH}_4} = (0.75)(7390 \text{ kPa}) + (0.25)(4640 \text{ kPa}) = 6683 \text{ kPa}$$

State 1 properties:

$$\left. \begin{array}{l} T_{R1} = \frac{T_1}{T_{\text{cr}}} = \frac{1300 \text{ K}}{276 \text{ K}} = 4.715 \\ P_{R1} = \frac{P_1}{P_{\text{cr}}} = \frac{1000 \text{ kPa}}{6683 \text{ kPa}} = 0.1496 \end{array} \right\} \begin{array}{l} Z_1 = 1.003 \\ Z_{h1} = -0.0064 \quad (\text{from EES}) \\ Z_{s1} = 0.001197 \end{array}$$

$$\Delta h_1 = Z_{h1} RT_{\text{cr}} = (-0.0064)(0.2246 \text{ kJ/kg.K})(276 \text{ K}) = -0.399 \text{ kJ/kg}$$

$$\begin{aligned} h_1 &= mf_{\text{CO}_2} h_{\text{CO}_2,1} + mf_{\text{CH}_4} h_{\text{CH}_4,1} - \Delta h_1 \\ &= (0.8917)(-7803) + (0.1083)(-831) - (-0.399) = -7047 \text{ kJ/kg} \\ \Delta s_1 &= Z_{s1} R = (0.001197)(0.2246 \text{ kJ/kg.K}) = 0.0002688 \text{ kJ/kg.K} \end{aligned}$$

$$\begin{aligned} s_1 &= mf_{\text{CO}_2} s_{\text{CO}_2,1} + mf_{\text{CH}_4} s_{\text{CH}_4,1} - \Delta s_1 \\ &= (0.8917)(6.068) + (0.1083)(16.22) - (0.0002688) = 7.1679 \text{ kJ/kg.K} \end{aligned}$$

The final state entropies cannot be determined at this point since the final temperature is not known. However, for an isentropic process, the entropy change is zero and the final temperature may be determined from

$$\begin{aligned} \Delta s_{\text{total}} &= mf_{\text{CO}_2} \Delta s_{\text{CO}_2} + mf_{\text{CH}_4} \Delta s_{\text{CH}_4} \\ 0 &= mf_{\text{CO}_2} (s_{\text{CO}_2,2} - s_{\text{CO}_2,1}) + mf_{\text{CH}_4} (s_{\text{CH}_4,2} - s_{\text{CH}_4,1}) \end{aligned}$$

The solution is obtained using EES to be

$$T_2 = 947 \text{ K}$$

The initial and final enthalpies and the changes in enthalpy are

$$\left. \begin{array}{l} T_{R2} = \frac{T_2}{T_{\text{cr}}} = \frac{947 \text{ K}}{276 \text{ K}} = 3.434 \\ P_{R2} = \frac{P_2}{P_{\text{cr}}} = \frac{100 \text{ kPa}}{6683 \text{ kPa}} = 0.015 \end{array} \right\} \begin{array}{l} Z_{h2} = -0.0004869 \\ Z_{s2} = 0.0004057 \quad (\text{from EES}) \end{array}$$

$$\Delta h_2 = Z_{h2} RT_{\text{cr}} = (-0.0004869)(0.2246 \text{ kJ/kg.K})(276 \text{ K}) = -0.03015 \text{ kJ/kg}$$

$$\begin{aligned} h_2 &= mf_{\text{CO}_2} h_{\text{CO}_2,2} + mf_{\text{CH}_4} h_{\text{CH}_4,2} - \Delta h_2 \\ &= (0.8917)(-8248) + (0.1083)(-2503) - (-0.03015) = -7625 \text{ kJ/kg} \end{aligned}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$\dot{Q}_{\text{in}} - \dot{W}_{\text{out}} = \dot{m} \Delta h_m \longrightarrow \dot{W}_{\text{out}} = -\dot{m}(h_2 - h_1)$$

where the mass flow rate is

$$\dot{m} = \frac{P_1 \dot{V}_1}{Z_1 RT_1} = \frac{(1000 \text{ kPa})(0.180 \text{ m}^3/\text{s})}{(1.003)(0.2246 \text{ kJ/kg.K})(1300 \text{ K})} = 0.6149 \text{ kg/s}$$

Substituting,

$$\dot{W}_{\text{out}} = -(0.6149 \text{ kg/s})[(-7625) - (-7047) \text{ kJ/kg}] = \mathbf{356 \text{ kW}}$$

13-101 A stream of gas mixture at a given pressure and temperature is to be separated into its constituents steadily. The minimum work required is to be determined.

Assumptions 1 Both the N₂ and CO₂ gases and their mixture are ideal gases. 2 This is a steady-flow process. 3 The kinetic and potential energy changes are negligible.

Properties The molar masses of N₂ and CO₂ are 28.0 and 44.0 kg/kmol. (Table A-1).

Analysis The minimum work required to separate a gas mixture into its components is equal to the reversible work associated with the mixing process, which is equal to the exergy destruction (or irreversibility) associated with the mixing process since

$$X_{\text{destroyed}} = W_{\text{rev,out}} - W_{\text{act,u}} \xrightarrow{\text{J}} = W_{\text{rev,out}} = T_0 S_{\text{gen}}$$

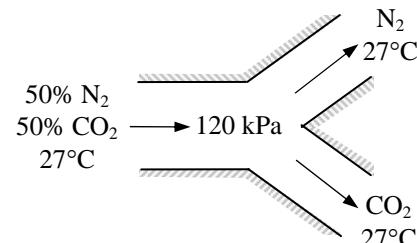

where S_{gen} is the entropy generation associated with the steady-flow mixing process. The entropy change associated with a constant pressure and temperature adiabatic mixing process is determined from

$$\bar{s}_{\text{gen}} = \sum \Delta \bar{s}_i = -R_u \sum y_i \ln y_i = -(8.314 \text{ kJ/kmol} \cdot \text{K})[0.5 \ln(0.5) + 0.5 \ln(0.5)] \\ = 5.763 \text{ kJ/kmol} \cdot \text{K}$$

$$M_m = \sum y_i M_i = (0.5)(28 \text{ kg/kmol}) + (0.5)(44 \text{ kg/kmol}) = 36 \text{ kg/kmol}$$

$$s_{\text{gen}} = \frac{\bar{s}_{\text{gen}}}{M_m} = \frac{5.763 \text{ kJ/kmol} \cdot \text{K}}{36 \text{ kg/kmol}} = 0.1601 \text{ kJ/kg} \cdot \text{K}$$

$$x_{\text{destroyed}} = T_0 s_{\text{gen}} = (300 \text{ K})(0.1601 \text{ kJ/kg} \cdot \text{K}) = 48.0 \text{ kJ/kg}$$

13-102E The mass percentages of a gas mixture are given. This mixture is expanded in an adiabatic, steady-flow turbine of specified isentropic efficiency. The second law efficiency and the exergy destruction during this expansion process are to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N₂, He, CH₄, and C₂H₆ are 28.0, 4.0, 16.0, and 30.0 lbm/lbmol, respectively (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.248, 1.25, 0.532, and 0.427 Btu/lbm·R, respectively (Table A-2Ea).

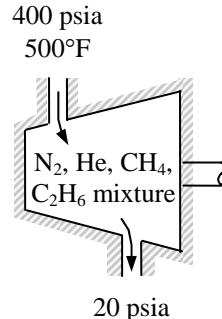

Analysis For 1 lbm of mixture, the mole numbers of each component are

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{0.15 \text{ lbm}}{28 \text{ lbm/lbmol}} = 0.005357 \text{ lbmol}$$

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{0.05 \text{ lbm}}{4 \text{ lbm/lbmol}} = 0.0125 \text{ lbmol}$$

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{0.6 \text{ lbm}}{16 \text{ lbm/lbmol}} = 0.0375 \text{ lbmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{0.20 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.006667 \text{ lbmol}$$

The mole number of the mixture is

$$N_m = N_{\text{O}_2} + N_{\text{CO}_2} + N_{\text{He}} = 0.005357 + 0.0125 + 0.0375 + 0.006667 = 0.06202 \text{ lbmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1 \text{ lbm}}{0.06202 \text{ lbmol}} = 16.12 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ lbm/lbmol}\cdot\text{R}}{16.12 \text{ lbm/lbmol}} = 0.1232 \text{ Btu/lbm}\cdot\text{R}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{\text{N}_2}c_{p,\text{N}_2} + mf_{\text{He}}c_{p,\text{He}} + mf_{\text{CH}_4}c_{p,\text{CH}_4} + mf_{\text{C}_2\text{H}_6}c_{p,\text{C}_2\text{H}_6} \\ &= 0.15 \times 0.248 + 0.05 \times 1.25 + 0.60 \times 0.532 + 0.20 \times 0.427 \\ &= 0.5043 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 0.5043 - 0.1232 = 0.3811 \text{ Btu/lbm}\cdot\text{R}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{0.5043}{0.3811} = 1.323$$

The temperature at the end of the expansion for the isentropic process is

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (960 \text{ R}) \left(\frac{20 \text{ psia}}{400 \text{ psia}} \right)^{0.323/1.323} = 462.0 \text{ R}$$

Using the definition of turbine isentropic efficiency, the actual outlet temperature is

$$T_2 = T_1 - \eta_{\text{turb}}(T_1 - T_{2s}) = (960 \text{ R}) - (0.85)(960 - 462.0) = 536.7 \text{ R}$$

The entropy change of the gas mixture is

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (0.5043) \ln \frac{536.7}{960} - (0.1232) \ln \frac{20}{400} = 0.07583 \text{ Btu/lbm}\cdot\text{R}$$

The actual work produced is

$$w_{\text{out}} = h_1 - h_2 = c_p(T_1 - T_2) = (0.5043 \text{ Btu/lbm} \cdot \text{R})(960 - 536.7) \text{ R} = 213.5 \text{ Btu/lbm}$$

The reversible work output is

$$w_{\text{rev,out}} = h_1 - h_2 - T_0(s_1 - s_2) = 213.5 \text{ Btu/lbm} - (537 \text{ R})(-0.07583 \text{ Btu/lbm} \cdot \text{R}) = 254.2 \text{ Btu/lbm}$$

The second-law efficiency and the exergy destruction are then

$$\eta_{\text{II}} = \frac{w_{\text{out}}}{w_{\text{rev,out}}} = \frac{213.5}{254.2} = 0.840 = \mathbf{84.0\%}$$

$$x_{\text{dest}} = w_{\text{rev,out}} - w_{\text{out}} = 254.2 - 213.5 = \mathbf{40.7 \text{ Btu/lbm}}$$

13-103 A program is to be written to determine the mole fractions of the components of a mixture of three gases with known molar masses when the mass fractions are given, and to determine the mass fractions of the components when the mole fractions are given. Also, the program is to be run for a sample case.

Analysis The problem is solved using EES, and the solution is given below.

```

Fundamentals of Engineering (FE) Exam Problems

13-105 An ideal gas mixture whose apparent molar mass is 20 kg/kmol consists of nitrogen N₂ and three other gases. If the mole fraction of nitrogen is 0.55, its mass fraction is

- (a) 0.15 (b) 0.23 (c) 0.39 (d) 0.55 (e) 0.77

Answer (e) 0.77

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
M_mix=20 "kg/kmol"
M_N2=28 "kg/kmol"
y_N2=0.55
mf_N2=(M_N2/M_mix)*y_N2
```

"Some Wrong Solutions with Common Mistakes:"

W1_mf = y_N2 "Taking mass fraction to be equal to mole fraction"
 W2_mf= y_N2*(M_mix/M_N2) "Using the molar mass ratio backwards"
 W3_mf= 1-mf_N2 "Taking the complement of the mass fraction"

13-106 An ideal gas mixture consists of 2 kmol of N₂ and 6 kmol of CO₂. The mass fraction of CO₂ in the mixture is

- (a) 0.175 (b) 0.250 (c) 0.500 (d) 0.750 (e) 0.825

Answer (e) 0.825

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

Dry and Atmospheric Air: Specific and Relative Humidity

14-1C Dry air does not contain any water vapor, but atmospheric air does.

14-2C Yes; by cooling the air at constant pressure.

14-3C Yes.

14-4C Specific humidity will decrease but relative humidity will increase.

14-5C Yes, the water vapor in the air can be treated as an ideal gas because of its very low partial pressure.

14-6C The same. This is because water vapor behaves as an ideal gas at low pressures, and the enthalpy of an ideal gas depends on temperature only.

14-7C Specific humidity is the amount of water vapor present in a unit mass of dry air. Relative humidity is the ratio of the actual amount of vapor in the air at a given temperature to the maximum amount of vapor air can hold at that temperature.

14-8C The specific humidity will remain constant, but the relative humidity will decrease as the temperature rises in a well-sealed room.

14-9C The specific humidity will remain constant, but the relative humidity will decrease as the temperature drops in a well-sealed room.

14-10C A tank that contains moist air at 3 atm is located in moist air that is at 1 atm. The driving force for moisture transfer is the vapor pressure difference, and thus it is possible for the water vapor to flow into the tank from surroundings if the vapor pressure in the surroundings is greater than the vapor pressure in the tank.

14-11C Insulations on *chilled water lines* are always wrapped with *vapor barrier jackets* to eliminate the possibility of vapor entering the insulation. This is because moisture that migrates through the insulation to the cold surface will condense and remain there indefinitely with no possibility of vaporizing and moving back to the outside.

14-12C When the temperature, total pressure, and the relative humidity are given, the vapor pressure can be determined from the psychrometric chart or the relation $P_v = \phi P_{\text{sat}}$ where P_{sat} is the saturation (or boiling) pressure of water at the specified temperature and ϕ is the relative humidity.

14-13 A tank contains dry air and water vapor at specified conditions. The specific humidity, the relative humidity, and the volume of the tank are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The specific humidity can be determined from its definition,

$$\omega = \frac{m_v}{m_a} = \frac{0.3 \text{ kg}}{21 \text{ kg}} = \mathbf{0.0143 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The saturation pressure of water at 30°C is

$$P_g = P_{\text{sat}} @ 30^\circ\text{C} = 4.2469 \text{ kPa}$$

Then the relative humidity can be determined from

21 kg dry air
0.3 kg H₂O vapor
30°C
100 kPa

$$\phi = \frac{\omega P}{(0.622 + \omega)P_g} = \frac{(0.0143)(100 \text{ kPa})}{(0.622 + 0.0143)(4.2469 \text{ kPa})} = \mathbf{52.9\%}$$

(c) The volume of the tank can be determined from the ideal gas relation for the dry air,

$$P_v = \phi P_g = (0.529)(4.2469 \text{ kPa}) = 2.245 \text{ kPa}$$

$$P_a = P - P_v = 100 - 2.245 = 97.755 \text{ kPa}$$

$$V = \frac{m_a R_a T}{P_a} = \frac{(21 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(303 \text{ K})}{97.755 \text{ kPa}} = \mathbf{18.7 \text{ m}^3}$$

14-14 A tank contains dry air and water vapor at specified conditions. The specific humidity, the relative humidity, and the volume of the tank are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The specific humidity can be determined from its definition,

$$\omega = \frac{m_v}{m_a} = \frac{0.3 \text{ kg}}{21 \text{ kg}} = \mathbf{0.0143 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The saturation pressure of water at 24°C is

$$P_g = P_{\text{sat } @ 24^\circ\text{C}} = 2.339 \text{ kPa}$$

Then the relative humidity can be determined from

$$\phi = \frac{\omega P}{(0.622 + \omega)P_g} = \frac{(0.0143)(100 \text{ kPa})}{(0.622 + 0.0143)2.339 \text{ kPa}} = 0.960 = \mathbf{96.0\%}$$

(c) The volume of the tank can be determined from the ideal gas relation for the dry air,

$$P_v = \phi P_g = (0.960)(2.339 \text{ kPa}) = 2.245 \text{ kPa}$$

$$P_a = P - P_v = 100 - 2.245 = 97.755 \text{ kPa}$$

$$V = \frac{m_a R_a T}{P_a} = \frac{(21 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(293 \text{ K})}{97.755 \text{ kPa}} = \mathbf{18.1 \text{ m}^3}$$

21 kg dry air
0.3 kg H ₂ O vapor
20°C
100 kPa

14-15 A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat } @ 20^\circ\text{C}} = (0.85)(2.3392 \text{ kPa}) = 1.988 \text{ kPa}$$

$$P_a = P - P_v = 98 - 1.988 = \mathbf{96.01 \text{ kPa}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(1.988 \text{ kPa})}{(98 - 1.988) \text{ kPa}} = \mathbf{0.0129 \text{ kg H}_2\text{O/kg dry air}}$$

AIR
20°C
98 kPa
85% RH

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \approx c_p T + \omega h_g \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0129)(2537.4 \text{ kJ/kg}) \\ &= \mathbf{52.78 \text{ kJ/kg dry air}} \end{aligned}$$

14-16 A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat} @ 20^\circ\text{C}} = (0.85)(2.3392 \text{ kPa}) = 1.988 \text{ kPa}$$

$$P_a = P - P_v = 85 - 1.988 = \mathbf{83.01 \text{ kPa}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(1.988 \text{ kPa})}{(85 - 1.988) \text{ kPa}} = \mathbf{0.0149 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$h = h_a + \omega h_v \approx c_p T + \omega h_g$$

$$= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0149)(2537.4 \text{ kJ/kg})$$

$$= \mathbf{57.90 \text{ kJ/kg dry air}}$$

AIR
20°C
85 kPa
85% RH

14-17E A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat} @ 85^\circ\text{F}} = (0.60)(0.5966 \text{ psia}) = 0.358 \text{ psia}$$

$$P_a = P - P_v = 13.5 - 0.358 = \mathbf{13.14 \text{ psia}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(0.358 \text{ psia})}{(13.5 - 0.358) \text{ psia}} = \mathbf{0.0169 \text{ lbm H}_2\text{O/lbm dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$h = h_a + \omega h_v \approx c_p T + \omega h_g$$

$$= (0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(85^\circ\text{F}) + (0.0169)(1098.3 \text{ Btu/lbm})$$

$$= \mathbf{39.01 \text{ Btu/lbm dry air}}$$

AIR
85°F
13.5 psia
60% RH

14-18 The masses of dry air and the water vapor contained in a room at specified conditions and relative humidity are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis The partial pressure of water vapor and dry air are determined to be

$$P_v = \phi P_g = \phi P_{\text{sat}} @ 23^\circ\text{C} = (0.50)(2.811 \text{ kPa}) = 1.41 \text{ kPa}$$

$$P_a = P - P_v = 98 - 1.41 = 96.59 \text{ kPa}$$

The masses are determined to be

$$m_a = \frac{P_a V}{R_a T} = \frac{(96.59 \text{ kPa})(240 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(296 \text{ K})} = 272.9 \text{ kg}$$

$$m_v = \frac{P_v V}{R_v T} = \frac{(1.41 \text{ kPa})(240 \text{ m}^3)}{(0.4615 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(296 \text{ K})} = 2.47 \text{ kg}$$

ROOM
240 m ³
23°C
98 kPa
50% RH

14-19E Humid air is expanded in an isentropic nozzle. The amount of water vapor that has condensed during the process is to be determined.

Assumptions The air and the water vapor are ideal gases.

Properties The specific heat ratio of air at room temperature is $k = 1.4$ (Table A-2a). The saturation properties of water are to be obtained from water tables.

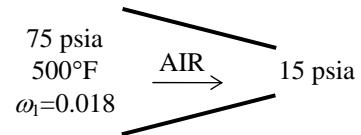

Analysis Since the mole fraction of the water vapor in this mixture is very small,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (960 \text{ R}) \left(\frac{15 \text{ psia}}{75 \text{ psia}} \right)^{0.4/1.4} = 606.1 \text{ R}$$

We will assume that the air leaves the nozzle at a relative humidity of 100% (will be verified later). The vapor pressure and specific humidity at the outlet are then

$$P_{v,2} = \phi_2 P_g = \phi_2 P_{\text{sat}} @ 146.1^\circ\text{F} = (1.0)(3.381 \text{ psia}) = 3.381 \text{ psia}$$

$$\omega_2 = \frac{0.622 P_{v,2}}{P - P_{v,2}} = \frac{(0.622)(3.381 \text{ psia})}{(15 - 3.381) \text{ psia}} = 0.181 \text{ lbm H}_2\text{O/lbm dry air}$$

This is greater than the inlet specific humidity (0.018 lbm/lbm dry air), and thus there will be no condensation of water vapor:

$$\Delta\omega = \omega_1 - \omega_2 = 0 \text{ lbm H}_2\text{O/lbm dry air}$$

14-20 Humid air is compressed in an isentropic compressor. The relative humidity of the air at the compressor outlet is to be determined.

Assumptions The air and the water vapor are ideal gases.

Properties The specific heat ratio of air at room temperature is $k = 1.4$ (Table A-2a). The saturation properties of water are to be obtained from water tables.

Analysis At the inlet,

$$P_{v,1} = \phi_1 P_{g,1} = \phi_1 P_{\text{sat} @ 20^\circ\text{C}} = (0.90)(2.3392 \text{ kPa}) = 2.105 \text{ kPa}$$

$$\omega_2 = \omega_1 = \frac{0.622 P_{v,1}}{P - P_{v,1}} = \frac{(0.622)(2.105 \text{ kPa})}{(100 - 2.105) \text{ kPa}} = 0.0134 \text{ kg H}_2\text{O/kg dry air}$$

Since the mole fraction of the water vapor in this mixture is very small,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (293 \text{ K}) \left(\frac{800 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 531 \text{ K}$$

The saturation pressure at this temperature is

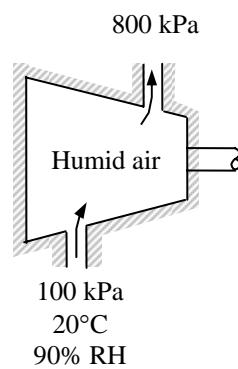

$$P_{g,2} = P_{\text{sat} @ 258^\circ\text{C}} = 4542 \text{ kPa} \text{ (from EES)}$$

The vapor pressure at the exit is

$$P_{v,2} = \frac{\omega_2 P_2}{\omega_2 + 0.622} = \frac{(0.0134)(800)}{0.0134 + 0.622} = 16.87 \text{ kPa}$$

The relative humidity at the exit is then

$$\phi_2 = \frac{P_{v,2}}{P_{g,2}} = \frac{16.87}{4542} = \mathbf{0.0037 = 0.37\%}$$

Dew-Point, Adiabatic Saturation, and Wet-bulb Temperatures

14-21C Dew-point temperature is the temperature at which condensation begins when air is cooled at constant pressure.

14-22C Andy's. The temperature of his glasses may be below the dew-point temperature of the room, causing condensation on the surface of the glasses.

14-23C The outer surface temperature of the glass may drop below the dew-point temperature of the surrounding air, causing the moisture in the vicinity of the glass to condense. After a while, the condensate may start dripping down because of gravity.

14-24C When the temperature falls below the dew-point temperature, dew forms on the outer surfaces of the car. If the temperature is below 0°C, the dew will freeze. At very low temperatures, the moisture in the air will freeze directly on the car windows.

14-25C When the air is saturated (100% relative humidity).

14-26C These two are approximately equal at atmospheric temperatures and pressure.

14-27 A house contains air at a specified temperature and relative humidity. It is to be determined whether any moisture will condense on the inner surfaces of the windows when the temperature of the window drops to a specified value.

Assumptions The air and the water vapor are ideal gases.

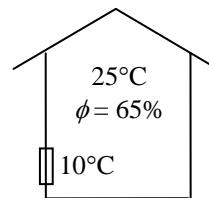

Analysis The vapor pressure P_v is uniform throughout the house, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.65)(3.1698 \text{ kPa}) = 2.06 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat} @ P_v = T_{sat} @ 2.06 \text{ kPa} = \mathbf{18.0^\circ\text{C}}$$

That is, the moisture in the house air will start condensing when the temperature drops below 18.0°C. Since the windows are at a lower temperature than the dew-point temperature, some moisture **will condense** on the window surfaces.

14-28 A person wearing glasses enters a warm room at a specified temperature and relative humidity from the cold outdoors. It is to be determined whether the glasses will get fogged.

Assumptions The air and the water vapor are ideal gases.

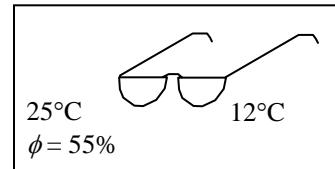

Analysis The vapor pressure P_v of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.55)(3.1698 \text{ kPa}) = 1.743 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 1.743 \text{ kPa}} = 15.3^\circ\text{C} \quad (\text{Table A-5 or EES})$$

That is, the moisture in the house air will start condensing when the air temperature drops below 15.3°C . Since the glasses are at a lower temperature than the dew-point temperature, some moisture will condense on the glasses, and thus they **will get fogged**.

14-29 A person wearing glasses enters a warm room at a specified temperature and relative humidity from the cold outdoors. It is to be determined whether the glasses will get fogged.

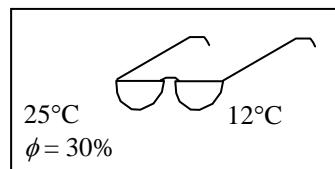

Assumptions The air and the water vapor are ideal gases.

Analysis The vapor pressure P_v of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.30)(3.1698 \text{ kPa}) = 0.9509 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.9509 \text{ kPa}} = 6.2^\circ\text{C} \quad (\text{Table A-5 or EES})$$

That is, the moisture in the house air will start condensing when the air temperature drops below 6.2°C . Since the glasses are at a higher temperature than the dew-point temperature, moisture will not condense on the glasses, and thus they **will not get fogged**.

14-30E A woman drinks a cool canned soda in a room at a specified temperature and relative humidity. It is to be determined whether the can will sweat.

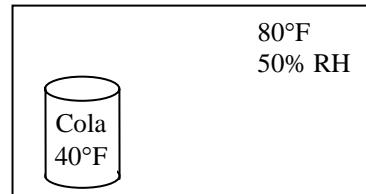

Assumptions The air and the water vapor are ideal gases.

Analysis The vapor pressure P_v of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 80^\circ\text{F} = (0.50)(0.50745 \text{ psia}) = 0.254 \text{ psia}$$

The dew-point temperature of the air in the house is

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.254 \text{ psia}} = 59.7^\circ\text{F} \quad (\text{from EES})$$

That is, the moisture in the house air will start condensing when the air temperature drops below 59.7°F . Since the canned drink is at a lower temperature than the dew-point temperature, some moisture will condense on the can, and thus it **will sweat**.

14-31 The dry- and wet-bulb temperatures of atmospheric air at a specified pressure are given. The specific humidity, the relative humidity, and the enthalpy of air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) We obtain the properties of water vapor from EES. The specific humidity ω_1 is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where T_2 is the wet-bulb temperature, and ω_2 is determined from

$$\omega_2 = \frac{0.622P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(1.938 \text{ kPa})}{(95 - 1.938) \text{ kPa}} = 0.01295 \text{ kg H}_2\text{O/kg dry air}$$

95 kPa
25°C
$T_{wb} = 17^\circ\text{C}$

Thus,

$$\omega_1 = \frac{(1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(17 - 25)^\circ\text{C} + (0.01295)(2460.6 \text{ kJ/kg})}{(2546.5 - 71.36) \text{ kJ/kg}} = \mathbf{0.00963 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The relative humidity ϕ_1 is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.00963)(95 \text{ kPa})}{(0.622 + 0.00963)(3.1698 \text{ kPa})} = 0.457 \text{ or } \mathbf{45.7\%}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h_1 &= h_{a1} + \omega_1 h_{v1} \cong c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.00963)(2546.5 \text{ kJ/kg}) \\ &= \mathbf{49.65 \text{ kJ/kg dry air}} \end{aligned}$$

14-32 The dry- and wet-bulb temperatures of air in room at a specified pressure are given. The specific humidity, the relative humidity, and the dew-point temperature are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) We obtain the properties of water vapor from EES. The specific humidity ω_1 is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where T_2 is the wet-bulb temperature, and ω_2 is determined from

$$\omega_2 = \frac{0.622P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(2.488 \text{ kPa})}{(100 - 2.488) \text{ kPa}} = 0.01587 \text{ kg H}_2\text{O/kg dry air}$$

100 kPa
26°C
$T_{wb} = 21^\circ\text{C}$

Thus,

$$\omega_1 = \frac{(1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(21 - 26)^\circ\text{C} + (0.01587)(2451.2 \text{ kJ/kg})}{(2548.3 - 88.10) \text{ kJ/kg}} = \mathbf{0.01377 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The relative humidity ϕ_1 is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.01377)(100 \text{ kPa})}{(0.622 + 0.01377)(3.3638 \text{ kPa})} = 0.644 \text{ or } \mathbf{64.4\%}$$

(c) The vapor pressure at the inlet conditions is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 26^\circ\text{C}} = (0.644)(3.3638 \text{ kPa}) = 2.166 \text{ kPa}$$

Thus the dew-point temperature of the air is

$$T_{dp} = T_{\text{sat} @ P_v} = T_{\text{sat} @ 2.166 \text{ kPa}} = \mathbf{18.8^\circ\text{C}}$$

14-33 EES Problem 14-32 is reconsidered. The required properties are to be determined using EES at 100 and 300 kPa pressures.

Analysis The problem is solved using EES, and the solution is given below.

```
Tdb=26 [C]
Twb=21 [C]
P1=100 [kPa]
P2=300 [kPa]
```

```
h1=enthalpy(AirH2O,T=Tdb,P=P1,B=Twb)
v1=volume(AirH2O,T=Tdb,P=P1,B=Twb)
Tdp1=dewpoint(AirH2O,T=Tdb,P=P1,B=Twb)
w1=humrat(AirH2O,T=Tdb,P=P1,B=Twb)
Rh1=relhum(AirH2O,T=Tdb,P=P1,B=Twb)

h2=enthalpy(AirH2O,T=Tdb,P=P2,B=Twb)
v2=volume(AirH2O,T=Tdb,P=P2,B=Twb)
Tdp2=dewpoint(AirH2O,T=Tdb,P=P2,B=Twb)
w2=humrat(AirH2O,T=Tdb,P=P2,B=Twb)
Rh2=relhum(AirH2O,T=Tdb,P=P2,B=Twb)
```

SOLUTION

```
h1=61.25 [kJ/kg]
h2=34.16 [kJ/kg]
P1=100 [kPa]
P2=300 [kPa]
Rh1=0.6437
Rh2=0.4475
Tdb=26 [C]
Tdp1=18.76
Tdp2=13.07
Twb=21 [C]
v1=0.8777 [m^3/kg]
v2=0.2877 [m^3/kg]
w1=0.01376 [kg/kg]
w2=0.003136 [kg/kg]
```

Alternative Solution

The following EES routine can also be used to solve this problem. The above EES routine uses built-in psychrometric functions whereas the one below uses analytical expressions together with steam properties.

"Given"

```
T_db=26 [C]
T_wb=21 [C]
P=100 [kPa]
```

"Properties"

```
Fluid$='steam_iapws'
P_g1=pressure(Fluid$, T=T_db, x=1)
P_g2=pressure(Fluid$, T=T_wb, x=1)
h_g1=enthalpy(Fluid$, T=T_db, x=1)
h_g2=enthalpy(Fluid$, T=T_wb, x=1)
h_f2=enthalpy(Fluid$, T=T_wb, x=0)
h_fg2=h_g2-h_f2
c_p=1.005 [kJ/kg-C] "for air"
```

"Analysis"
"(a)"
 $w_2 = (0.622*P_g2)/(P-P_g2)$ "kg H₂O/kg dry air"
 $w_1 = (c_p*(T_wb-T_db) + w_2*h_fg2)/(h_g1-h_f2)$
"(b)"
 $\phi_1 = (w_1*P)/((0.622+w_1)*P_g1)$
"(c)"
 $P_v1 = \phi_1 * P_g1$
 $T_dp = \text{temperature}(\text{Fluid\$}, P=P_v1, x=1)$

SOLUTION

$c_p = 1.005$ [kJ/kg-C]
 $\text{Fluid\$} = \text{'steam_iapws'}$
 $h_f2 = 88.1$ [kJ/kg]
 $h_fg2 = 2451.2$ [kJ/kg]
 $h_g1 = 2548.3$ [kJ/kg]
 $h_g2 = 2539.3$ [kJ/kg]
 $P = 100$ [kPa]
 $\phi_1 = 0.6439$
 $P_g1 = 3.3638$ [kPa]
 $P_g2 = 2.488$ [kPa]
 $P_v1 = 2.166$ [kPa]
 $T_db = 26$ [C]
 $T_dp = 18.8$ [C]
 $T_wb = 21$ [C]
 $w_1 = 0.01377$
 $w_2 = 0.01587$

14-34E The dry- and wet-bulb temperatures of air in room at a specified pressure are given. The specific humidity, the relative humidity, and the dew-point temperature are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The specific humidity ω_1 is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where T_2 is the wet-bulb temperature, and ω_2 is determined from

14.7 psia
80°F
 $T_{wb} = 65^\circ\text{F}$

$$\omega_2 = \frac{0.622P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(0.30578 \text{ psia})}{(14.7 - 0.30578) \text{ psia}} = 0.01321 \text{ lbm H}_2\text{O/lbm dry air}$$

Thus,

$$\omega_1 = \frac{(0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(65 - 80)^\circ\text{F} + (0.01321)(1056.5 \text{ Btu/lbm})}{(1096.1 - 33.08) \text{ Btu/lbm}} = \mathbf{0.00974 \text{ lbm H}_2\text{O/lbm dry air}}$$

(b) The relative humidity ϕ_1 is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.00974)(14.7 \text{ psia})}{(0.622 + 0.00974)(0.50745 \text{ psia})} = 0.447 \text{ or } \mathbf{44.7\%}$$

(c) The vapor pressure at the inlet conditions is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 70^\circ\text{F}} = (0.447)(0.50745 \text{ psia}) = 0.2268 \text{ psia}$$

Thus the dew-point temperature of the air is

$$T_{dp} = T_{\text{sat} @ P_v} = T_{\text{sat} @ 0.2268 \text{ psia}} = \mathbf{56.6^\circ\text{F}} \quad (\text{from EES})$$

14-35 Atmospheric air flows steadily into an adiabatic saturation device and leaves as a saturated vapor. The relative humidity and specific humidity of air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The exit state of the air is completely specified, and the total pressure is 98 kPa. The properties of the moist air at the exit state may be determined from EES to be

$$h_2 = 78.11 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.02079 \text{ kg H}_2\text{O/kg dry air}$$

The enthalpy of makeup water is

$$h_{w2} = h_{f@ 25^\circ\text{C}} = 104.83 \text{ kJ/kg} \quad (\text{Table A - 4})$$

An energy balance on the control volume gives

$$h_1 + (\omega_2 - \omega_1)h_w = h_2$$

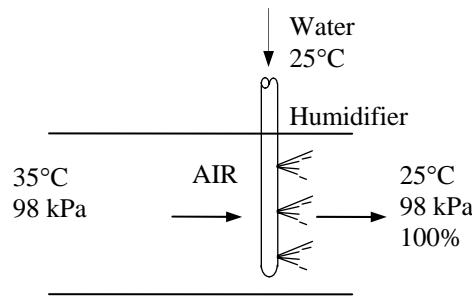

$$h_1 + (0.02079 - \omega_1)(104.83 \text{ kJ/kg}) = 78.11 \text{ kJ/kg}$$

Pressure and temperature are known for inlet air. Other properties may be determined from this equation using EES. A hand solution would require a trial-error approach. The results are

$$h_1 = 77.66 \text{ kJ/kg dry air}$$

$$\omega_1 = \mathbf{0.01654 \text{ kg H}_2\text{O/kg dry air}}$$

$$\phi_1 = \mathbf{0.4511}$$

Psychrometric Chart

14-36C They are very nearly parallel to each other.

14-37C The saturation states (located on the saturation curve).

14-38C By drawing a horizontal line until it intersects with the saturation curve. The corresponding temperature is the dew-point temperature.

14-39C No, they cannot. The enthalpy of moist air depends on ω , which depends on the total pressure.

 **14-40** The pressure, temperature, and relative humidity of air in a room are specified. Using the psychrometric chart, the specific humidity, the enthalpy, the wet-bulb temperature, the dew-point temperature, and the specific volume of the air are to be determined.

Analysis From the psychrometric chart (Fig. A-31) we read

- (a) $\omega = 0.0087 \text{ kg H}_2\text{O} / \text{kg dry air}$
- (b) $h = 45.4 \text{ kJ/kg dry air}$
- (c) $T_{wb} = 16.3^\circ\text{C}$
- (d) $T_{dp} = 12.0^\circ\text{C}$
- (e) $v = 0.851 \text{ m}^3 / \text{kg dry air}$

14-41 Problem 14-40 is reconsidered. The required properties are to be determined using EES. Also, the properties are to be obtained at an altitude of 2000 m.

Analysis The problem is solved using EES, and the solution is given below.

$$T_{db}=23 \text{ [C]}$$

$$Rh=0.50$$

$$P_1=101.325 \text{ [kPa]}$$

$$Z = 2000 \text{ [m]}$$

$$P_2=101.325*(1-0.02256*Z*\text{convert(m,km)})^5.256 \text{ "Relation giving P as a function of altitude"}$$

```

h1=enthalpy(AirH2O,T=Tdb,P=P1,R=Rh)
v1=volume(AirH2O,T=Tdb,P=P1,R=Rh)
Tdp1=dewpoint(AirH2O,T=Tdb,P=P1,R=Rh)
w1=humrat(AirH2O,T=Tdb,P=P1,R=Rh)
Twb1=wetbulb(AirH2O,T=Tdb,P=P1,R=Rh)

h2=enthalpy(AirH2O,T=Tdb,P=P2,R=Rh)
v2=volume(AirH2O,T=Tdb,P=P2,R=Rh)
Tdp2=dewpoint(AirH2O,T=Tdb,P=P2,R=Rh)
w2=humrat(AirH2O,T=Tdb,P=P2,R=Rh)
Twb2=wetbulb(AirH2O,T=Tdb,P=P2,R=Rh)

```

SOLUTION

$$h_1=45.4 \text{ [kJ/kg]}$$

$$h_2=51.62 \text{ [kJ/kg]}$$

$$P_1=101.3 \text{ [kPa]}$$

$$P_2=79.49 \text{ [kPa]}$$

$$Rh=0.5$$

$$T_{db}=23 \text{ [C]}$$

$$Tdp1=12.03 \text{ [C]}$$

$$Tdp2=12.03 \text{ [C]}$$

$$Twb1=16.25 \text{ [C]}$$

$$Twb2=15.67 \text{ [C]}$$

$$v1=0.8507 \text{ [m}^3/\text{kg]}$$

$$v2=1.089 \text{ [m}^3/\text{kg]}$$

$$w1=0.008747 \text{ [kg/kg]}$$

$$w2=0.01119 \text{ [kg/kg]}$$

$$Z=2000 \text{ [m]}$$

Discussion The atmospheric pressure for a given elevation can also be obtained from Table A-16 of the book.

14-42 The pressure and the dry- and wet-bulb temperatures of air in a room are specified. Using the psychrometric chart, the specific humidity, the enthalpy, the relative humidity, the dew-point temperature, and the specific volume of the air are to be determined.

Analysis From the psychrometric chart (Fig. A-31) we read

$$(a) \omega = 0.0092 \text{ kg H}_2\text{O} / \text{kg dry air}$$

$$(b) h = 47.6 \text{ kJ} / \text{kg dry air}$$

$$(c) \phi = 49.6\%$$

$$(d) T_{dp} = 12.8^\circ\text{C}$$

$$(e) v = 0.855 \text{ m}^3 / \text{kg dry air}$$

14-43 Problem 14-42 is reconsidered. The required properties are to be determined using EES. Also, the properties are to be obtained at an altitude of 3000 m.

Analysis The problem is solved using EES, and the solution is given below.

$$T_{db}=24 \text{ [C]}$$

$$T_{wb}=17 \text{ [C]}$$

$$P_1=101.325 \text{ [kPa]}$$

$$Z=3000 \text{ [m]}$$

$$P_2=101.325*(1-0.02256*Z*convert(m,km))^5.256 \text{ "Relation giving P as function of altitude"}$$

$$T_{wb}=17 \text{ [C]}$$

$$v_1=0.8542 \text{ [m}^3/\text{kg}]$$

$$v_2=1.245 \text{ [m}^3/\text{kg}]$$

$$w_1=0.009219 \text{ [kg/kg]}$$

$$w_2=0.01475 \text{ [kg/kg]}$$

$$Z=3000 \text{ [m]}$$

Discussion The atmospheric pressure for a given elevation can also be obtained from Table A-16 of the book.

14-44E The pressure, temperature, and relative humidity of air are specified. Using the psychrometric chart, the wet-bulb temperature, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

Analysis From the psychrometric chart in Fig. A-31E or using EES psychrometric functions we obtain

$$(a) T_{wb} = 81.6^{\circ}\text{C}$$

$$(b) \omega = 0.0214 \text{ lbm H}_2\text{O / lbm dry air}$$

$$(c) h = 45.2 \text{ Btu/lbm dry air}$$

$$(d) T_{dp} = 78.9^{\circ}\text{F}$$

$$(e) P_v = \phi P_g = \phi P_{\text{sat}} @ 90^{\circ}\text{F} = (0.70)(0.69904 \text{ psia}) = 0.489 \text{ psia}$$

Air
1 atm
90°F
70% RH

14-45 The pressure, temperature, and wet-bulb temperature of air are specified. Using the psychrometric chart, the relative humidity, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

Analysis From the psychrometric chart in Fig. A-31 or using EES psychrometric functions we obtain

$$(a) \phi = 0.242 = 24.2\%$$

$$(b) \omega = 0.0072 \text{ kg H}_2\text{O / kg dry air}$$

$$(c) h = 50.6 \text{ kJ/kg dry air}$$

$$(d) T_{dp} = 9.1^{\circ}\text{C}$$

$$(e) P_v = \phi P_g = \phi P_{\text{sat}} @ 32^{\circ}\text{C} = (0.242)(4.760 \text{ kPa}) = 1.15 \text{ kPa}$$

Air
1 atm
32°C
$T_{wb}=18^{\circ}\text{C}$

14-46 The pressure, temperature, and wet-bulb temperature of air are specified. The adiabatic saturation temperature is to be determined.

Analysis For an adiabatic saturation process, we obtained Eq. 14-14 in the text,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

This requires a trial-error solution for the adiabatic saturation temperature, T_2 . The inlet state properties are

$$\omega_1 = 0.0072 \text{ kg H}_2\text{O / kg dry air}$$

$$h_{g1} = h_g @ 32^\circ\text{C} = 2559.2 \text{ kJ/kg}$$

As a first estimate, let us take $T_2 = 18^\circ\text{C}$ (the inlet wet-bulb temperature). Also, at the exit, the relative humidity is 100% ($\phi_2 = 1$) and the pressure is 1 atm. Other properties at the exit state are

$$\omega_2 = 0.0130 \text{ kg H}_2\text{O / kg dry air}$$

$$h_{f2} = h_f @ 18^\circ\text{C} = 75.54 \text{ kJ/kg (Table A - 4)}$$

$$h_{fg2} = h_{fg} @ 18^\circ\text{C} = 2458.3 \text{ kJ/kg (Table A - 4)}$$

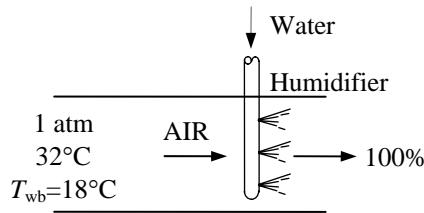

Substituting,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}} = \frac{(1.005)(18 - 32) + (0.0130)(2458.3)}{2559.2 - 75.54} = 0.00720 \text{ kg H}_2\text{O / kg dry air}$$

which is equal to the inlet specific humidity. Therefore, the adiabatic saturation temperature is

$$T_2 = 18^\circ\text{C}$$

Discussion This result is not surprising since the wet-bulb and adiabatic saturation temperatures are approximately equal to each other for air-water mixtures at atmospheric pressure.

14-47E The pressure, temperature, and wet-bulb temperature of air are specified. Using the psychrometric chart, the relative humidity, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

Analysis From the psychrometric chart in Fig. A-31E or using EES psychrometric functions we obtain

$$(a) \phi = 0.615 = 61.5\%$$

$$(b) \omega = 0.0188 \text{ lbm H}_2\text{O / lbm dry air}$$

$$(c) h = 42.3 \text{ Btu/lbm dry air}$$

$$(d) T_{wb} = 78.9^\circ\text{F}$$

$$(e) P_v = \phi P_{sat} = \phi P_{sat} @ 28^\circ\text{C} = (0.615)(0.69904 \text{ psia}) = 0.430 \text{ psia}$$

Air
1 atm
90°F
$T_{dp}=75^\circ\text{F}$

14-48E The pressure, temperature, and wet-bulb temperature of air are specified. The adiabatic saturation temperature is to be determined.

Analysis For an adiabatic saturation process, we obtained Eq. 14-14 in the text,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

This requires a trial-error solution for the adiabatic saturation temperature, T_2 . The inlet state properties are

$$\omega_1 = 0.0188 \text{ lbm H}_2\text{O / lbm dry air } (\text{Fig. A-31E})$$

$$h_{g1} = h_g @ 90^\circ\text{F} = 1100.4 \text{ Btu/lbm } (\text{Table A-4E})$$

As a first estimate, let us take $T_2 = 78.9^\circ\text{F} \approx 79^\circ\text{F}$ (the inlet wet-bulb temperature). Also, at the exit, the relative humidity is 100% ($\phi_2 = 1$) and the pressure is 1 atm. Other properties at the exit state are

$$\omega_2 = 0.0215 \text{ lbm H}_2\text{O / lbm dry air}$$

$$h_{f2} = h_f @ 79^\circ\text{F} = 47.07 \text{ Btu/lbm } (\text{Table A-4E})$$

$$h_{fg2} = h_{fg} @ 79^\circ\text{F} = 1048.6 \text{ Btu/lbm } (\text{Table A-4E})$$

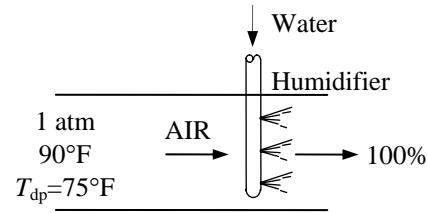

Substituting,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}} = \frac{(0.240)(79 - 90) + (0.0215)(1048.6)}{1100.4 - 47.07} = 0.0189 \text{ lbm H}_2\text{O / lbm dry air}$$

which is sufficiently close to the inlet specific humidity (0.0188). Therefore, the adiabatic saturation temperature is

$$T_2 \approx 79^\circ\text{F}$$

Discussion This result is not surprising since the wet-bulb and adiabatic saturation temperatures are approximately equal to each other for air-water mixtures at atmospheric pressure.

Human Comfort and Air-Conditioning

14-49C It humidifies, dehumidifies, cleans and even deodorizes the air.

14-50C (a) Perspires more, (b) cuts the blood circulation near the skin, and (c) sweats excessively.

14-51C It is the direct heat exchange between the body and the surrounding surfaces. It can make a person feel chilly in winter, and hot in summer.

14-52C It affects by removing the warm, moist air that builds up around the body and replacing it with fresh air.

14-53C The spectators. Because they have a lower level of activity, and thus a lower level of heat generation within their bodies.

14-54C Because they have a large skin area to volume ratio. That is, they have a smaller volume to generate heat but a larger area to lose it from.

14-55C It affects a body's ability to perspire, and thus the amount of heat a body can dissipate through evaporation.

14-56C Humidification is to add moisture into an environment, dehumidification is to remove it.

14-57C The metabolism refers to the burning of foods such as carbohydrates, fat, and protein in order to perform the necessary bodily functions. The metabolic rate for an average man ranges from 108 W while reading, writing, typing, or listening to a lecture in a classroom in a seated position to 1250 W at age 20 (730 at age 70) during strenuous exercise. The corresponding rates for women are about 30 percent lower. Maximum metabolic rates of trained athletes can exceed 2000 W. We are interested in metabolic rate of the occupants of a building when we deal with heating and air conditioning because the metabolic rate represents the rate at which a body generates heat and dissipates it to the room. This body heat contributes to the heating in winter, but it adds to the cooling load of the building in summer.

14-58C The metabolic rate is proportional to the size of the body, and the metabolic rate of women, in general, is lower than that of men because of their smaller size. Clothing serves as insulation, and the thicker the clothing, the lower the environmental temperature that feels comfortable.

14-59C Sensible heat is the energy associated with a temperature change. The sensible heat loss from a human body increases as (a) the skin temperature increases, (b) the environment temperature decreases, and (c) the air motion (and thus the convection heat transfer coefficient) increases.

14-60C Latent heat is the energy released as water vapor condenses on cold surfaces, or the energy absorbed from a warm surface as liquid water evaporates. The latent heat loss from a human body increases as (a) the skin wetness increases and (b) the relative humidity of the environment decreases. The rate of evaporation from the body is related to the rate of latent heat loss by $\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg}$ where h_{fg} is the latent heat of vaporization of water at the skin temperature.

14-61 A department store expects to have a specified number of people at peak times in summer. The contribution of people to the sensible, latent, and total cooling load of the store is to be determined.

Assumptions There is a mix of men, women, and children in the classroom.

Properties The average rate of heat generation from people doing light work is 115 W, and 70% of it is in sensible form (see Sec. 14-6).

Analysis The contribution of people to the sensible, latent, and total cooling load of the store are

$$\dot{Q}_{\text{people, total}} = (\text{No. of people}) \times \dot{Q}_{\text{person, total}} = 245 \times (115 \text{ W}) = \mathbf{28,180 \text{ W}}$$

$$\dot{Q}_{\text{people, sensible}} = (\text{No. of people}) \times \dot{Q}_{\text{person, sensible}} = 245 \times (0.7 \times 115 \text{ W}) = \mathbf{19,720 \text{ W}}$$

$$\dot{Q}_{\text{people, latent}} = (\text{No. of people}) \times \dot{Q}_{\text{person, latent}} = 245 \times (0.3 \times 115 \text{ W}) = \mathbf{8450 \text{ W}}$$

14-62E There are a specified number of people in a movie theater in winter. It is to be determined if the theater needs to be heated or cooled.

Assumptions There is a mix of men, women, and children in the classroom.

Properties The average rate of heat generation from people in a movie theater is 105 W, and 70 W of it is in sensible form and 35 W in latent form.

Analysis Noting that only the sensible heat from a person contributes to the heating load of a building, the contribution of people to the heating of the building is

$$\dot{Q}_{\text{people, sensible}} = (\text{No. of people}) \times \dot{Q}_{\text{person, sensible}} = 500 \times (70 \text{ W}) = 35,000 \text{ W} = \mathbf{119,420 \text{ Btu/h}}$$

since 1 W = 3.412 Btu/h. The building needs to be heated since the heat gain from people is less than the rate of heat loss of 130,000 Btu/h from the building.

14-63 The infiltration rate of a building is estimated to be 0.9 ACH. The sensible, latent, and total infiltration heat loads of the building at sea level are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air infiltrates at the outdoor conditions, and exfiltrates at the indoor conditions. 3 Excess moisture condenses at room temperature of 24°C. 4 The effect of water vapor on air density is negligible.

Properties The gas constant and the specific heat of air are $R = 0.287 \text{ kPa.m}^3/\text{kg.K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{°C}$ (Table A-2). The heat of vaporization of water at 24°C is $h_{fg} = h_{fg} @ 24^\circ\text{C} = 2444.1 \text{ kJ/kg}$ (Table A-4). The properties of the ambient and room air are determined from the psychrometric chart (Fig. A-31) to be

$$\left. \begin{array}{l} T_{\text{ambient}} = 38^\circ\text{C} \\ \phi_{\text{ambient}} = 35\% \end{array} \right\} w_{\text{ambient}} = 0.01458 \text{ kg/kg dryair}$$

$$\left. \begin{array}{l} T_{\text{room}} = 24^\circ\text{C} \\ \phi_{\text{room}} = 55\% \end{array} \right\} w_{\text{room}} = 0.01024 \text{ kg/kg dryair}$$

Analysis Noting that the infiltration of ambient air will cause the air in the cold storage room to be changed 0.9 times every hour, the air will enter the room at a mass flow rate of

$$\rho_{\text{ambient}} = \frac{P_0}{RT_0} = \frac{101.325 \text{ kPa}}{(0.287 \text{ kPa.m}^3/\text{kg.K})(38 + 273 \text{ K})} = 1.135 \text{ kg/m}^3$$

$$\dot{m}_{\text{air}} = \rho_{\text{ambient}} V_{\text{room}} \text{ACH} = (1.135 \text{ kg/m}^3)(20 \times 13 \times 3 \text{ m}^3)(0.9 \text{ h}^{-1}) = 797.0 \text{ kg/h} = 0.2214 \text{ kg/s}$$

Then the sensible, latent, and total infiltration heat loads of the room are determined to be

$$\dot{Q}_{\text{infiltration, sensible}} = \dot{m}_{\text{air}} c_p (T_{\text{ambient}} - T_{\text{room}}) = (0.2214 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{°C})(38 - 24)^\circ\text{C} = 3.11 \text{ kW}$$

$$\dot{Q}_{\text{infiltration, latent}} = \dot{m}_{\text{air}} (w_{\text{ambient}} - w_{\text{room}}) h_{fg} = (0.2214 \text{ kg/s})(0.01458 - 0.01024)(2444.1 \text{ kJ/kg}) = 2.35 \text{ kW}$$

$$\dot{Q}_{\text{infiltration, total}} = \dot{Q}_{\text{infiltration, sensible}} + \dot{Q}_{\text{infiltration, latent}} = 3.11 + 2.35 = 5.46 \text{ kW}$$

Discussion The specific volume of the dry air at the ambient conditions could also be determined from the psychrometric chart at ambient conditions.

14-64 The infiltration rate of a building is estimated to be 1.8 ACH. The sensible, latent, and total infiltration heat loads of the building at sea level are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air infiltrates at the outdoor conditions, and exfiltrates at the indoor conditions. 3 Excess moisture condenses at room temperature of 24°C. 4 The effect of water vapor on air density is negligible.

Properties The gas constant and the specific heat of air are $R = 0.287 \text{ kPa.m}^3/\text{kg.K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{°C}$ (Table A-2). The heat of vaporization of water at 24°C is $h_{fg} = h_{fg} @ 24^\circ\text{C} = 2444.1 \text{ kJ/kg}$ (Table A-4). The properties of the ambient and room air are determined from the psychrometric chart (Fig. A-31) to be

$$\left. \begin{array}{l} T_{\text{ambient}} = 38^\circ\text{C} \\ \phi_{\text{ambient}} = 35\% \end{array} \right\} w_{\text{ambient}} = 0.01458 \text{ kg/kg dryair}$$

$$\left. \begin{array}{l} T_{\text{room}} = 24^\circ\text{C} \\ \phi_{\text{room}} = 55\% \end{array} \right\} w_{\text{room}} = 0.01024 \text{ kg/kg dryair}$$

Analysis Noting that the infiltration of ambient air will cause the air in the cold storage room to be changed 1.8 times every hour, the air will enter the room at a mass flow rate of

$$\rho_{\text{ambient}} = \frac{P_0}{RT_0} = \frac{101.325 \text{ kPa}}{(0.287 \text{ kPa.m}^3/\text{kg.K})(38 + 273 \text{ K})} = 1.135 \text{ kg/m}^3$$

$$\dot{m}_{\text{air}} = \rho_{\text{ambient}} V_{\text{room}} \text{ACH} = (1.135 \text{ kg/m}^3)(20 \times 13 \times 3 \text{ m}^3)(1.8 \text{ h}^{-1}) = 1594 \text{ kg/h} = 0.4427 \text{ kg/s}$$

Then the sensible, latent, and total infiltration heat loads of the room are determined to be

$$\dot{Q}_{\text{infiltration, sensible}} = \dot{m}_{\text{air}} c_p (T_{\text{ambient}} - T_{\text{room}}) = (0.4427 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{°C})(38 - 24)^\circ\text{C} = 6.23 \text{ kW}$$

$$\dot{Q}_{\text{infiltration, latent}} = \dot{m}_{\text{air}} (w_{\text{ambient}} - w_{\text{room}}) h_{fg} = (0.4427 \text{ kg/s})(0.01458 - 0.01024)(2444.1 \text{ kJ/kg}) = 4.69 \text{ kW}$$

$$\dot{Q}_{\text{infiltration, total}} = \dot{Q}_{\text{infiltration, sensible}} + \dot{Q}_{\text{infiltration, latent}} = 6.23 + 4.69 = 10.92 \text{ kW}$$

Discussion The specific volume of the dry air at the ambient conditions could also be determined from the psychrometric chart at ambient conditions.

14-65 An average person produces 0.25 kg of moisture while taking a shower. The contribution of showers of a family of four to the latent heat load of the air-conditioner per day is to be determined.

Assumptions All the water vapor from the shower is condensed by the air-conditioning system.

Properties The latent heat of vaporization of water is given to be 2450 kJ/kg.

Analysis The amount of moisture produced per day is

$$\begin{aligned} \dot{m}_{\text{vapor}} &= (\text{Moisture produced per person})(\text{No. of persons}) \\ &= (0.25 \text{ kg / person})(4 \text{ persons / day}) = 1 \text{ kg / day} \end{aligned}$$

Then the latent heat load due to showers becomes

$$\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg} = (1 \text{ kg / day})(2450 \text{ kJ / kg}) = 2450 \text{ kJ / day}$$

14-66 There are 100 chickens in a breeding room. The rate of total heat generation and the rate of moisture production in the room are to be determined.

Assumptions All the moisture from the chickens is condensed by the air-conditioning system.

Properties The latent heat of vaporization of water is given to be 2430 kJ/kg. The average metabolic rate of chicken during normal activity is 10.2 W (3.78 W sensible and 6.42 W latent).

Analysis The total rate of heat generation of the chickens in the breeding room is

$$\dot{Q}_{\text{gen, total}} = \dot{q}_{\text{gen, total}} (\text{No. of chickens}) = (10.2 \text{ W / chicken})(100 \text{ chickens}) = \mathbf{1020 \text{ W}}$$

The latent heat generated by the chicken and the rate of moisture production are

$$\begin{aligned}\dot{Q}_{\text{gen, latent}} &= \dot{q}_{\text{gen, latent}} (\text{No. of chickens}) \\ &= (6.42 \text{ W/chicken})(100 \text{ chickens}) = 642 \text{ W} \\ &= 0.642 \text{ kW}\end{aligned}$$

$$\dot{m}_{\text{moisture}} = \frac{\dot{Q}_{\text{gen, latent}}}{h_{fg}} = \frac{0.642 \text{ kJ / s}}{2430 \text{ kJ / kg}} = 0.000264 \text{ kg / s} = \mathbf{0.264 \text{ g / s}}$$

Simple Heating and Cooling

14-67C Relative humidity decreases during a simple heating process and increases during a simple cooling process. Specific humidity, on the other hand, remains constant in both cases.

14-68C Because a horizontal line on the psychrometric chart represents a $\omega = \text{constant}$ process, and the moisture content ω of air remains constant during these processes.

14-69 Humid air at a specified state is cooled at constant pressure to the dew-point temperature. The cooling required for this process is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 71.3 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0161 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

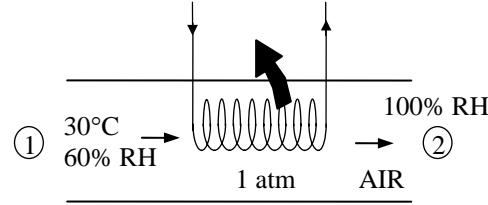

$$T_{dp,1} = 21.4^\circ\text{C}$$

The exit state enthalpy is

$$\left. \begin{array}{l} P = 1 \text{ atm} \\ T_2 = T_{dp,1} = 21.4^\circ\text{C} \\ \phi_2 = 1 \end{array} \right\} h_2 = 62.4 \text{ kJ/kg dry air}$$

From the energy balance on air in the cooling section,

$$q_{out} = h_1 - h_2 = 71.3 - 62.4 = \mathbf{8.9 \text{ kJ/kg dry air}}$$

14-70E Humid air at a specified state is heated at constant pressure to a specified temperature. The relative humidity at the exit and the amount of heat required are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 40 psia. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 50^\circ\text{F} = (0.90)(0.17812 \text{ psia}) = 0.16031 \text{ psia}$$

$$h_{g1} = h_g @ 50^\circ\text{F} = 1083.1 \text{ Btu/lbm}$$

$$\begin{aligned}\omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.16031 \text{ psia})}{(40 - 0.16031) \text{ psia}} \\ &= 0.002503 \text{ lbm H}_2\text{O/lbm dry air}\end{aligned}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1}$$

$$= (0.240 \text{ Btu/lbm}\cdot^\circ\text{F})(50^\circ\text{F}) + (0.002503)(1083.1 \text{ Btu/lbm}) = 14.71 \text{ Btu/lbm dry air}$$

$$P_{v2} = P_{v1} = 0.16031 \text{ psia}$$

$$P_{g2} = P_{\text{sat}} @ 120^\circ\text{F} = 1.6951 \text{ psia}$$

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{0.16031 \text{ psia}}{1.6951 \text{ psia}} = 0.0946 = \mathbf{9.46\%}$$

$$h_{g2} = h_g @ 120^\circ\text{F} = 1113.2 \text{ Btu/lbm}$$

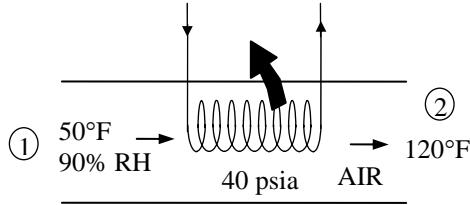

$$\omega_2 = \omega_1$$

$$h_2 = c_p T_2 + \omega_2 h_{g2}$$

$$= (0.240 \text{ Btu/lbm}\cdot^\circ\text{F})(120^\circ\text{F}) + (0.002503)(1113.2 \text{ Btu/lbm}) = 31.59 \text{ Btu/lbm dry air}$$

From the energy balance on air in the heating section,

$$q_{\text{in}} = h_2 - h_1 = 31.59 - 14.71 = \mathbf{16.9 \text{ Btu/lbm dry air}}$$

14-71 Air enters a cooling section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature, the exit relative humidity of the air, and the exit velocity are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31 or EES) to be

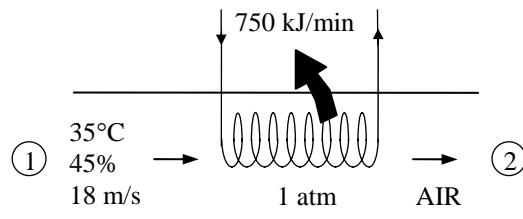

$$h_1 = 76.14 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01594 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$v_1 = 0.8953 \text{ m}^3 / \text{kg dry air}$$

The mass flow rate of dry air through the cooling section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{v_1} V_1 A_1 \\ &= \frac{1}{(0.8953 \text{ m}^3 / \text{kg})} (18 \text{ m/s})(\pi \times 0.3^2 / 4 \text{ m}^2) \\ &= 1.421 \text{ kg/s} \end{aligned}$$

From the energy balance on air in the cooling section,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= \dot{m}_a (h_2 - h_1) \\ -(750 / 60) \text{ kJ/s} &= (1.421 \text{ kg/s})(h_2 - 76.14) \text{ kJ/kg} \\ h_2 &= 67.35 \text{ kJ/kg dry air} \end{aligned}$$

(b) The exit state of the air is fixed now since we know both h_2 and ω_2 . From the psychrometric chart at this state we read

$$T_2 = 26.5^\circ\text{C}$$

$$\phi_2 = 73.1\%$$

$$v_2 = 0.8706 \text{ m}^3 / \text{kg dry air}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{v_1} = \frac{\dot{V}_2}{v_2} \longrightarrow \frac{V_1 A}{v_1} = \frac{V_2 A}{v_2}$$

$$V_2 = \frac{v_2}{v_1} V_1 = \frac{0.8706}{0.8953} (18 \text{ m/s}) = 17.5 \text{ m/s}$$

14-72 Air enters a cooling section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature, the exit relative humidity of the air, and the exit velocity are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31 or EES) to be

$$h_1 = 76.14 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01594 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$v_1 = 0.8953 \text{ m}^3 / \text{kg dry air}$$

The mass flow rate of dry air through the cooling section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{v_1} V_1 A_1 \\ &= \frac{1}{(0.8953 \text{ m}^3 / \text{kg})} (18 \text{ m/s})(\pi \times 0.3^2 / 4 \text{ m}^2) \\ &= 1.421 \text{ kg/s} \end{aligned}$$

From the energy balance on air in the cooling section,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= \dot{m}_a (h_2 - h_1) \\ -(1100 / 60) \text{ kJ/s} &= (1.421 \text{ kg/s})(h_2 - 76.14) \text{ kJ/kg} \\ h_2 &= 63.24 \text{ kJ/kg dry air} \end{aligned}$$

(b) The exit state of the air is fixed now since we know both h_2 and ω_2 . From the psychrometric chart at this state we read

$$T_2 = 22.6^\circ\text{C}$$

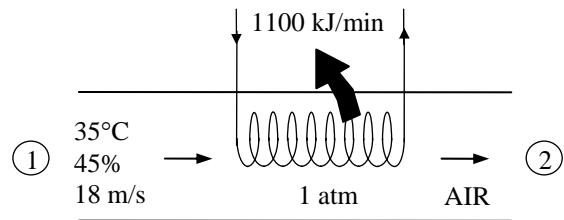

$$\phi_2 = 92.6\%$$

$$v_2 = 0.8591 \text{ m}^3 / \text{kg dry air}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{v_1} = \frac{\dot{V}_2}{v_2} \longrightarrow \frac{V_1 A}{v_1} = \frac{V_2 A}{v_2}$$

$$V_2 = \frac{v_2}{v_1} V_1 = \frac{0.8591}{0.8953} (18 \text{ m/s}) = 17.3 \text{ m/s}$$

14-73 Saturated humid air at a specified state is heated to a specified temperature. The relative humidity at the exit and the rate of heat transfer are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 200 kPa. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 15^\circ\text{C}} = (1.0)(1.7057 \text{ kPa}) = 1.7057 \text{ kPa}$$

$$h_{g1} = h_g @ 15^\circ\text{C} = 2528.3 \text{ kJ/kg}$$

$$P_{a1} = P_1 - P_{v1} = 200 - 1.7057 = 198.29 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}}$$

$$= \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(288 \text{ K})}{198.29 \text{ kPa}}$$

$$= 0.4168 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.7057 \text{ kPa})}{(200 - 1.7057) \text{ kPa}} = 0.005350 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(15^\circ\text{C}) + (0.005350)(2528.3 \text{ kJ/kg}) = 28.60 \text{ kJ/kg dry air}$$

$$P_{v2} = P_{g1} = 1.7057 \text{ kPa}$$

$$P_{g2} = P_{\text{sat} @ 30^\circ\text{C}} = 4.2469 \text{ kPa}$$

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{1.7057 \text{ kPa}}{4.2469 \text{ kPa}} = 0.402 = \mathbf{40.2\%}$$

$$h_{g2} = h_g @ 30^\circ\text{C} = 2555.6 \text{ kJ/kg}$$

$$\omega_2 = \omega_1$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.005350)(2555.6 \text{ kJ/kg}) = 43.82 \text{ kJ/kg dry air}$$

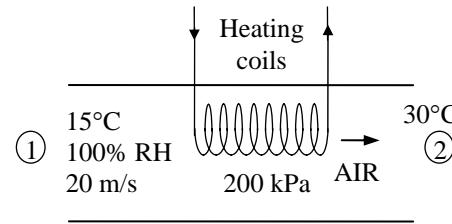

Then,

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (20 \text{ m/s}) \left(\frac{\pi(0.04 \text{ m})^2}{4} \right) = 0.02513 \text{ m}^3/\text{s}$$

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{0.02513 \text{ m}^3 / \text{s}}{0.4168 \text{ m}^3 / \text{kg dry air}} = 0.06029 \text{ kg/s}$$

From the energy balance on air in the heating section,

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (0.06029 \text{ kg/s})(43.82 - 28.60) \text{ kJ/kg} = \mathbf{0.918 \text{ kW}}$$

14-74 Saturated humid air at a specified state is heated to a specified temperature. The rate at which the exergy of the humid air is increased is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 200 kPa. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 15^\circ\text{C}} = (1.0)(1.7057 \text{ kPa}) = 1.7057 \text{ kPa}$$

$$h_{g1} = h_g @ 15^\circ\text{C} = 2528.3 \text{ kJ/kg}$$

$$s_{g1} = s_g @ 15^\circ\text{C} = 8.7803 \text{ kJ/kg} \cdot \text{K}$$

$$P_{a1} = P_1 - P_{v1} = 200 - 1.7057 = 198.29 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(288 \text{ K})}{198.29 \text{ kPa}} = 0.4168 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.7057 \text{ kPa})}{(200 - 1.7057) \text{ kPa}} = 0.005350 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot \text{C})(15^\circ\text{C}) + (0.005350)(2528.3 \text{ kJ/kg}) = 28.60 \text{ kJ/kg dry air}$$

$$P_{v2} = P_{v1} = 1.7057 \text{ kPa}$$

$$P_{g2} = P_{\text{sat} @ 30^\circ\text{C}} = 4.2469 \text{ kPa}$$

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{1.7057 \text{ kPa}}{4.2469 \text{ kPa}} = 0.402 = \mathbf{40.2\%}$$

$$P_{a2} = P_2 - P_{v2} = 200 - 1.7057 = 198.29 \text{ kPa}$$

$$h_{g2} = h_g @ 30^\circ\text{C} = 2555.6 \text{ kJ/kg}$$

$$s_{g2} = s_g @ 30^\circ\text{C} = 8.4520 \text{ kJ/kg} \cdot \text{K}$$

$$\omega_2 = \omega_1$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot \text{C})(30^\circ\text{C}) + (0.005350)(2555.6 \text{ kJ/kg}) = 43.82 \text{ kJ/kg dry air}$$

The entropy change of the dry air is

$$(s_2 - s_1)_{\text{dry air}} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} = (1.005) \ln \frac{303}{288} - (0.287) \ln \frac{198.29}{198.29} = 0.05103 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of the air-water mixture is

$$s_2 - s_1 = (s_2 - s_1)_{\text{dry air}} + \omega(s_2 - s_1)_{\text{water vapor}} = 0.05103 + (0.005350)(8.4520 - 8.7803) = 0.04927 \text{ kJ/kg} \cdot \text{K}$$

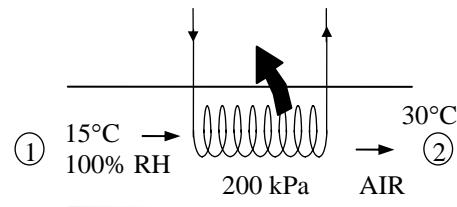

The mass flow rate of the dry air is

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (20 \text{ m/s}) \left(\frac{\pi (0.04 \text{ m})^2}{4} \right) = 0.02513 \text{ m}^3/\text{s}$$

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{0.02513 \text{ m}^3 / \text{s}}{0.4168 \text{ m}^3 / \text{kg dry air}} = 0.06029 \text{ kg/s}$$

The exergy increase of the humid air during this process is then,

$$\begin{aligned} \Delta\Phi &= \dot{m}_a (\psi_2 - \psi_1) = \dot{m}_a [(h_2 - h_1) - T_0(s_2 - s_1)] \\ &= (0.06029 \text{ kg/s})[(43.82 - 28.60) \text{ kJ/kg} - (288 \text{ K})(0.04927 \text{ kJ/kg} \cdot \text{K})] = \mathbf{0.062 \text{ kW}} \end{aligned}$$

Heating with Humidification

14-75C To achieve a higher level of comfort. Very dry air can cause dry skin, respiratory difficulties, and increased static electricity.

14-76 Air is first heated and then humidified by water vapor. The amount of steam added to the air and the amount of heat transfer to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 31.1 \text{ kJ / kg dry air}$$

$$\omega_1 = 0.0064 \text{ kg H}_2\text{O / kg dry air} (= \omega_2)$$

$$h_2 = 36.2 \text{ kJ / kg dry air}$$

$$h_3 = 58.1 \text{ kJ / kg dry air}$$

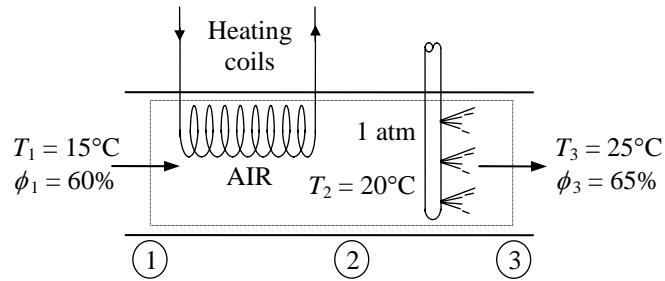

$$\omega_3 = 0.0129 \text{ kg H}_2\text{O / kg dry air}$$

Analysis (a) The amount of moisture in the air remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The amount of steam added to the air in the heating section is

$$\Delta\omega = \omega_3 - \omega_2 = 0.0129 - 0.0064 = \mathbf{0.0065 \text{ kg H}_2\text{O / kg dry air}}$$

(b) The heat transfer to the air in the heating section per unit mass of air is

$$q_{in} = h_2 - h_1 = 36.2 - 31.1 = \mathbf{5.1 \text{ kJ / kg dry air}}$$

14-77E Air is first heated and then humidified by water vapor. The amount of steam added to the air and the amount of heat transfer to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E or EES) to be

$$h_1 = 12.40 \text{ Btu/lbm dry air}$$

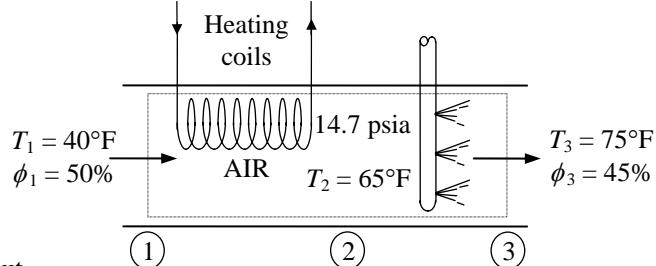

$$\omega_1 = 0.002586 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_2 = 18.44 \text{ Btu/lbm dry air}$$

$$\omega_2 = \omega_1 = 0.002586 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_3 = 27.10 \text{ Btu/lbm dry air}$$

$$\omega_3 = 0.008298 \text{ lbm H}_2\text{O/lbm dry air}$$

Analysis (a) The amount of moisture in the air remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The amount of steam added to the air in the heating section is

$$\Delta\omega = \omega_3 - \omega_2 = 0.008298 - 0.002586 = \mathbf{0.0057 \text{ lbm H}_2\text{O/lbm dry air}}$$

(b) The heat transfer to the air in the heating section per unit mass of air is

$$q_{in} = h_2 - h_1 = 18.44 - 12.40 = \mathbf{6.0 \text{ Btu/lbm dry air}}$$

14-78 Air is first heated and then humidified by wet steam. The temperature and relative humidity of air at the exit of heating section, the rate of heat transfer, and the rate at which water is added to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 23.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0053 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$v_1 = 0.809 \text{ m}^3/\text{kg dry air}$$

$$h_3 = 42.3 \text{ kJ/kg dry air}$$

$$\omega_3 = 0.0087 \text{ kg H}_2\text{O/kg dry air}$$

Analysis (a) The amount of moisture in the air remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{35 \text{ m}^3/\text{min}}{0.809 \text{ m}^3/\text{kg}} = 43.3 \text{ kg/min}$$

Noting that $Q = W = 0$, the energy balance on the humidifying section can be expressed as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{no (steady)}} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\begin{aligned} \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad \longrightarrow \quad \dot{m}_w h_w + \dot{m}_{a2} h_2 = \dot{m}_a h_3 \\ (\omega_3 - \omega_2) h_w + h_2 &= h_3 \end{aligned}$$

Solving for h_2 ,

$$h_2 = h_3 - (\omega_3 - \omega_2) h_g @ 100^\circ\text{C} = 42.3 - (0.0087 - 0.0053)(2675.6) = 33.2 \text{ kJ/kg dry air}$$

Thus at the exit of the heating section we have $\omega_2 = 0.0053 \text{ kg H}_2\text{O dry air}$ and $h_2 = 33.2 \text{ kJ/kg dry air}$, which completely fixes the state. Then from the psychrometric chart we read

$$T_2 = 19.5^\circ\text{C}$$

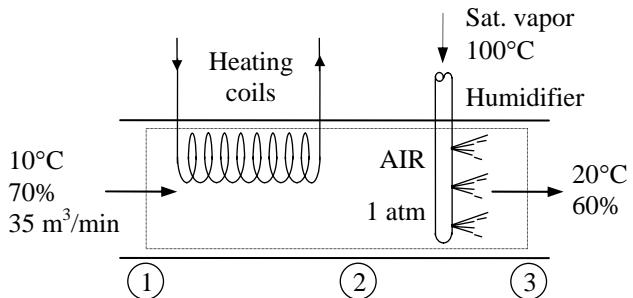

$$\phi_2 = 37.8\%$$

(b) The rate of heat transfer to the air in the heating section is

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (43.3 \text{ kg/min})(33.2 - 23.5) \text{ kJ/kg} = \mathbf{420 \text{ kJ/min}}$$

(c) The amount of water added to the air in the humidifying section is determined from the conservation of mass equation of water in the humidifying section,

$$\dot{m}_w = \dot{m}_a (\omega_3 - \omega_2) = (43.3 \text{ kg/min})(0.0087 - 0.0053) = \mathbf{0.15 \text{ kg/min}}$$

14-79 Air is first heated and then humidified by wet steam. The temperature and relative humidity of air at the exit of heating section, the rate of heat transfer, and the rate at which water is added to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air also remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. The properties of the air at various states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 10^\circ\text{C} = (0.70)(1.2281 \text{ kPa}) = 0.860 \text{ kPa} (= P_{v2})$$

$$P_{a1} = P_1 - P_{v1} = 95 - 0.860 = 94.14 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(283 \text{ K})}{94.14 \text{ kPa}} = 0.863 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.86 \text{ kPa})}{(95 - 0.86) \text{ kPa}} = 0.00568 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot \text{C})(10^\circ\text{C}) + (0.00568)(2519.2 \text{ kJ/kg}) = 24.36 \text{ kJ/kg dry air}$$

$$P_{v3} = \phi_3 P_{g3} = \phi_3 P_{\text{sat}} @ 20^\circ\text{C} = (0.60)(2.3392 \text{ kPa}) = 1.40 \text{ kPa}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}} = \frac{0.622(1.40 \text{ kPa})}{(95 - 1.40) \text{ kPa}} = 0.00930 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = c_p T_3 + \omega_3 h_{g3} = (1.005 \text{ kJ/kg} \cdot \text{C})(20^\circ\text{C}) + (0.0093)(2537.4 \text{ kJ/kg}) = 43.70 \text{ kJ/kg dry air}$$

Also, $\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{35 \text{ m}^3 / \text{min}}{0.863 \text{ m}^3 / \text{kg}} = 40.6 \text{ kg/min}$

Noting that $Q = W = 0$, the energy balance on the humidifying section gives

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{10(steady)}} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i \longrightarrow \dot{m}_w h_w + \dot{m}_{a2} h_2 = \dot{m}_a h_3 \longrightarrow (\omega_3 - \omega_2) h_w + h_2 = h_3$$

$$h_2 = h_3 - (\omega_3 - \omega_2) h_g @ 100^\circ\text{C} = 43.7 - (0.0093 - 0.00568) \times 2675.6 = 34.0 \text{ kJ/kg dry air}$$

Thus at the exit of the heating section we have $\omega = 0.00568 \text{ kg H}_2\text{O dry air}$ and $h_2 = 34.0 \text{ kJ/kg dry air}$, which completely fixes the state. The temperature of air at the exit of the heating section is determined from the definition of enthalpy,

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82 T_2)$$

$$34.0 = (1.005)T_2 + (0.00568)(2500.9 + 1.82T_2)$$

Solving for T_2 , yields

$$T_2 = 19.5^\circ\text{C}$$

The relative humidity at this state is

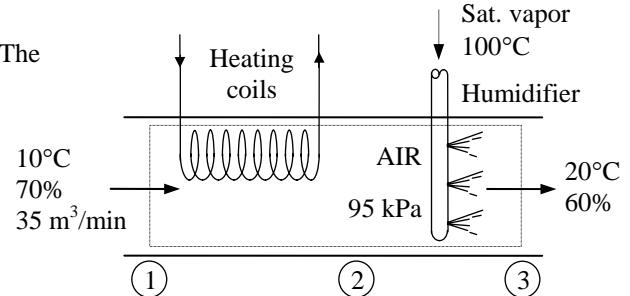

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{P_{v2}}{P_{\text{sat}} @ 19.5^\circ\text{C}} = \frac{0.860 \text{ kPa}}{2.2759 \text{ kPa}} = 0.377 \text{ or } 37.7\%$$

(b) The rate of heat transfer to the air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (40.6 \text{ kg/min})(34.0 - 24.36) \text{ kJ/kg} = 391 \text{ kJ/min}$$

(c) The amount of water added to the air in the humidifying section is determined from the conservation of mass equation of water in the humidifying section,

$$\dot{m}_w = \dot{m}_a (\omega_3 - \omega_2) = (40.6 \text{ kg/min})(0.0093 - 0.00568) = 0.147 \text{ kg/min}$$

Cooling with Dehumidification

14-80C To drop its relative humidity to more desirable levels.

14-81E Air is cooled and dehumidified at constant pressure. The amount of water removed from the air and the cooling requirement are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 52.2 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0278 \text{ kg H}_2\text{O/kg dry air}$$

and

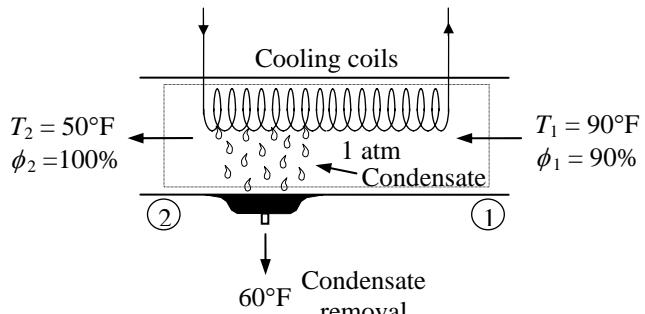

$$\phi_2 = 1.0$$

$$h_2 = 20.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0076 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \equiv h_f @ 60^\circ\text{F} = 28.08 \text{ Btu/lbm} \quad (\text{Table A-4})$$

Analysis The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\Delta\omega = \omega_1 - \omega_2 = 0.0278 - 0.0076 = \mathbf{0.0202 \text{ lbm H}_2\text{O/lbm dry air}}$$

Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta\dot{E}_{system} \xrightarrow{\text{0(steady)}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$q_{out} = h_1 - h_2 - (\omega_1 - \omega_2)h_w$$

$$= (52.2 - 20.3)\text{Btu/lbm} - (0.0202)(28.08)$$

$$= \mathbf{31.3 \text{ Btu/lbm dry air}}$$

14-82 Air is cooled and dehumidified at constant pressure. The amount of water removed from the air and the rate of cooling are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 79.6 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0202 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.881 \text{ m}^3/\text{kg dry air}$$

and

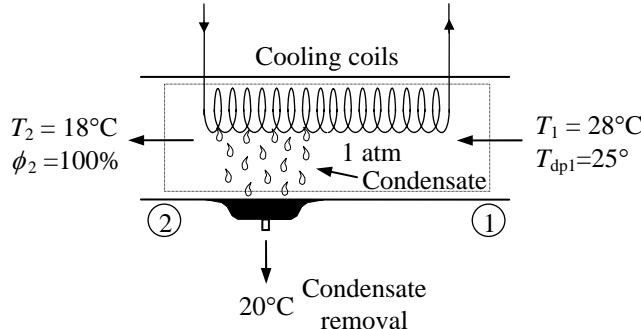

$$\phi_2 = 1.0$$

$$h_2 = 51.0 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0130 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \equiv h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg} \quad (\text{Table A-4})$$

Analysis The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The mass flow rate of air is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{(10,000 / 3600) \text{ m}^3 / \text{s}}{0.881 \text{ m}^3 / \text{kg dry air}} = 3.153 \text{ kg/s}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (3.153 \text{ kg/s})(0.0202 - 0.0130) = \mathbf{0.0227 \text{ kg/s}}$$

Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \xrightarrow{\text{sh0 (steady)}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

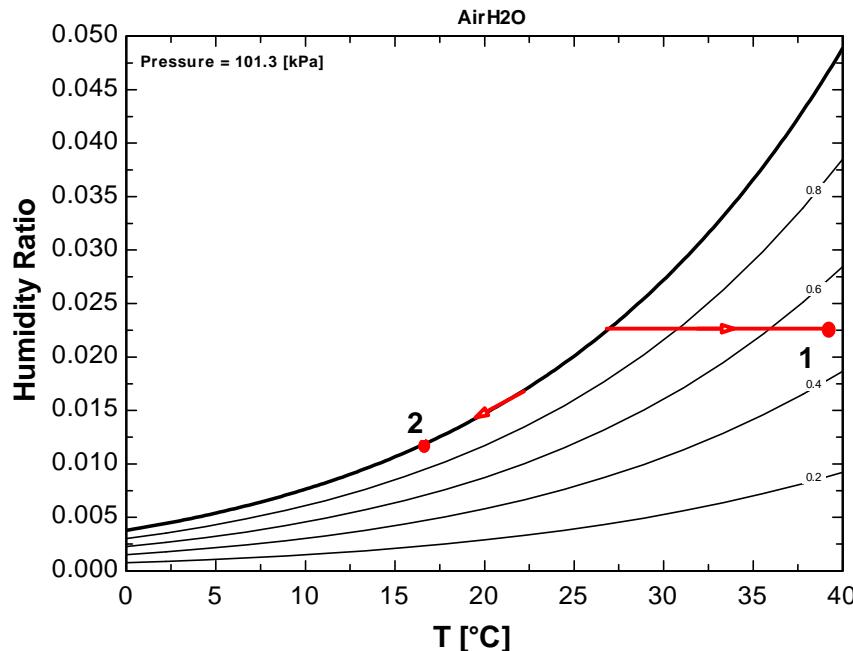

$$\dot{Q}_{out} = (3.153 \text{ kg/s})(79.6 - 51.0) \text{ kJ/kg} - (0.0227 \text{ kg/s})(83.915 \text{ kJ/kg})$$

$$= \mathbf{88.3 \text{ kW}}$$

14-83 Air is cooled and dehumidified at constant pressure. The system hardware and the psychrometric diagram are to be sketched and the inlet volume flow rate is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Properties (a) The schematic of the cooling and dehumidification process and the the process on the psychrometric chart are given below. The psychrometric chart is obtained from the Property Plot feature of EES.

(b) The inlet and the exit states of the air are completely specified, and the total pressure is 101.3 kPa (1 atm). The properties of the air at the inlet and exit states are determined from the psychrometric chart (Figure A-31 or EES) to be

$$T_{dp} = 26.7^\circ\text{C}$$

$$h_1 = 96.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0222 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.916 \text{ m}^3/\text{kg dry air}$$

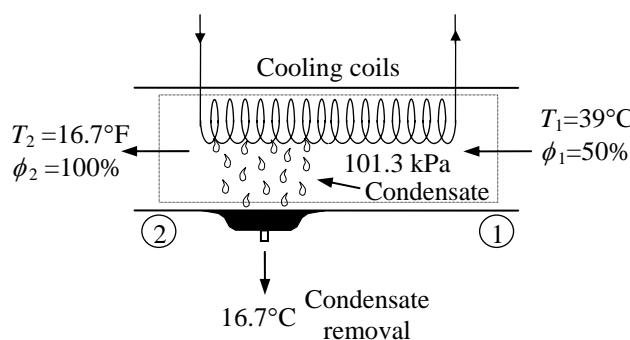

and

$$T_2 = T_2 - 10 = 26.7 - 10 = 16.7^\circ\text{C}$$

$$\phi_2 = 1.0$$

$$h_2 = 46.9 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0119 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \equiv h_f @ 16.7^\circ\text{C} = 70.10 \text{ kJ/kg} \quad (\text{Table A-4})$$

Analysis Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2)$$

Energy Balance:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{for steady state}} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e \\ \dot{Q}_{\text{out}} &= \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) \\ &= \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w \\ &= \dot{m}_a (h_1 - h_2) - \dot{m}_a (\omega_1 - \omega_2) h_w\end{aligned}$$

Solving for the mass flow rate of dry air,

$$\dot{m}_a = \frac{\dot{Q}_{\text{out}}}{(h_1 - h_2) - (\omega_1 - \omega_2) h_w} = \frac{1340 \text{ kW}}{(96.5 - 46.9) \text{ kJ/kg} - (0.0222 - 0.0119)(70.1 \text{ kJ/kg})} = 27.4 \text{ kg/s}$$

The volume flow rate is then determined from

$$\dot{V}_1 = \dot{m}_a v_1 = (27.4 \text{ kg/s})(0.916 \text{ m}^3/\text{kg}) = \mathbf{25.1 \text{ m}^3/s}$$

14-84E Saturated humid air at a specified state is cooled at constant pressure to a specified temperature. The rate at which liquid water is formed and the rate of cooling are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 70 psia. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 200^{\circ}\text{F} = (1.0)(11.538 \text{ psia}) = 11.538 \text{ psia}$$

$$h_{g1} = h_g @ 200^{\circ}\text{F} = 1145.7 \text{ Btu/lbm}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(11.538 \text{ psia})}{(70 - 11.538) \text{ psia}} = 0.1228 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (0.240 \text{ Btu/lbm} \cdot ^{\circ}\text{F})(200^{\circ}\text{F}) + (0.1228)(1145.7 \text{ Btu/lbm}) = 188.7 \text{ Btu/lbm dry air}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(660 \text{ K})}{(70 - 11.538) \text{ psia}} = 4.182 \text{ ft}^3 / \text{lbm dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}} @ 100^{\circ}\text{F} = (1.0)(0.95052 \text{ psia}) = 0.95052 \text{ psia}$$

$$h_{g2} = h_g @ 100^{\circ}\text{F} = 1104.7 \text{ Btu/lbm}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(0.95052 \text{ psia})}{(70 - 0.95052) \text{ psia}} = 0.00856 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (0.240 \text{ Btu/lbm} \cdot ^{\circ}\text{F})(100^{\circ}\text{F}) + (0.00856)(1104.7 \text{ Btu/lbm}) = 33.46 \text{ Btu/lbm dry air}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit:

$$h_w \equiv h_f @ 150^{\circ}\text{F} = 117.99 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

The mass flow rate of the dry air is

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (50 \text{ ft/s}) \left(\frac{\pi (3/12 \text{ ft})^2}{4} \right) = 2.454 \text{ ft}^3/\text{s}$$

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{2.454 \text{ ft}^3 / \text{s}}{4.182 \text{ ft}^3 / \text{lbm dry air}} = 0.5868 \text{ lbm/s}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = (0.5868 \text{ lbm/s})(0.1228 - 0.00856) = \mathbf{0.0670 \text{ lbm/s}}$$

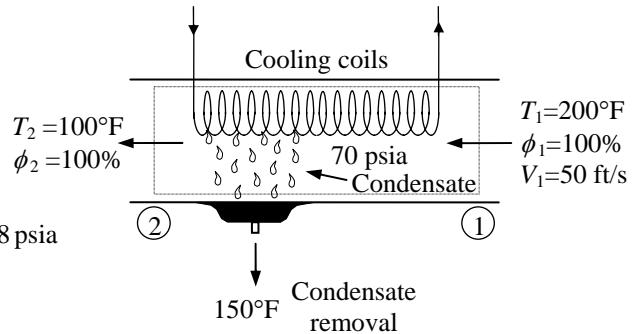

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{sh0 (steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\begin{aligned} \dot{Q}_{\text{out}} &= \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) \\ &= \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w \\ &= (0.5868 \text{ lbm})(188.7 - 33.46) \text{ Btu/lbm} - (0.06704 \text{ lbm})(117.99 \text{ Btu/lbm}) \\ &= \mathbf{83.2 \text{ Btu/s}} \end{aligned}$$

14-85 Air is first cooled, then dehumidified, and finally heated. The temperature of air before it enters the heating section, the amount of heat removed in the cooling section, and the amount of heat supplied in the heating section are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air decreases due to dehumidification ($\omega_3 < \omega_1$), and remains constant during heating ($\omega_3 = \omega_2$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The intermediate state (state 2) is also known since $\phi_2 = 100\%$ and $\omega_2 = \omega_3$. Therefore, we can determine the properties of the air at all three states from the psychrometric chart (Fig. A-31) to be

$$h_1 = 95.2 \text{ kJ / kg dry air}$$

$$\omega_1 = 0.0238 \text{ kg H}_2\text{O / kg dry air}$$

and

$$h_3 = 43.1 \text{ kJ / kg dry air}$$

$$\omega_3 = 0.0082 \text{ kg H}_2\text{O / kg dry air} (= \omega_2)$$

Also,

$$h_w \approx h_f @ 10^\circ\text{C} = 42.02 \text{ kJ/kg (Table A - 4)}$$

$$h_2 = 31.8 \text{ kJ/kg dry air}$$

$$T_2 = 11.1^\circ\text{C}$$

(b) The amount of heat removed in the cooling section is determined from the energy balance equation applied to the cooling section,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{0 (steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{\text{out,cooling}}$$

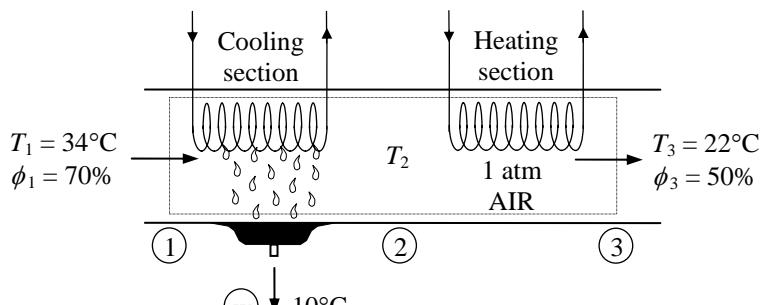

$$\dot{Q}_{\text{out,cooling}} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

or, per unit mass of dry air,

$$\begin{aligned} q_{\text{out,cooling}} &= (h_1 - h_2) - (\omega_1 - \omega_2) h_w \\ &= (95.2 - 31.8) - (0.0238 - 0.0082) 42.02 \\ &= 62.7 \text{ kJ/kg dry air} \end{aligned}$$

(c) The amount of heat supplied in the heating section per unit mass of dry air is

$$q_{\text{in,heating}} = h_3 - h_2 = 43.1 - 31.8 = 11.3 \text{ kJ / kg dry air}$$

14-86 Air is cooled by passing it over a cooling coil through which chilled water flows. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The saturation pressure of water at 32°C is 4.76 kPa (Table A-4). Then the dew point temperature of the incoming air stream at 32°C becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.7 \times 4.76 \text{ kPa}} = 25.8^\circ\text{C} \quad (\text{Table A-5})$$

since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense. The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$h_1 = 86.35 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.02114 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.8939 \text{ m}^3/\text{kg dry air}$$

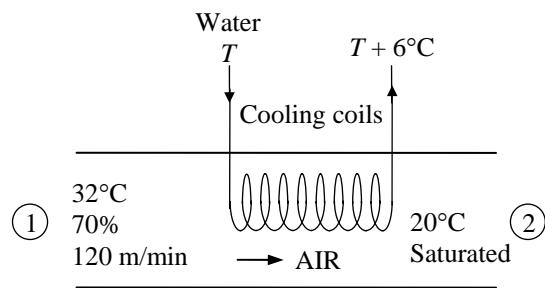

and

$$h_2 = 57.43 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O/kg dry air}$$

$$v_2 = 0.8501 \text{ m}^3/\text{kg dry air}$$

$$\text{Also, } h_w \equiv h_f @ 20^\circ\text{C} = 83.91 \text{ kJ/kg} \quad (\text{Table A-4})$$

Then,

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (120 \text{ m/min}) \left(\frac{\pi (0.4 \text{ m})^2}{4} \right) = 15.08 \text{ m}^3/\text{min}$$

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{15.08 \text{ m}^3/\text{min}}{0.8939 \text{ m}^3/\text{kg dry air}} = 16.87 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the water),

$$\text{Water Mass Balance: } \sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (16.87 \text{ kg/min})(0.02114 - 0.0147) = 0.1086 \text{ kg/min}$$

$$\text{Energy Balance: } \dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system}^{(0 \text{ steady})} = 0 \longrightarrow \dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{out} \longrightarrow Q_{out} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (16.87 \text{ kg/min})(86.35 - 57.43) \text{ kJ/kg} - (0.1086 \text{ kg/min})(83.91 \text{ kJ/kg}) = \mathbf{478.7 \text{ kJ/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{cooling \text{ water}} = \dot{m}_{cooling \text{ water}} \Delta h = \dot{m}_{cooling \text{ water}} c_p \Delta T$$

$$\dot{m}_{cooling \text{ water}} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{478.7 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(6^\circ\text{C})} = \mathbf{19.09 \text{ kg/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{v_1} = \frac{\dot{V}_2}{v_2} \longrightarrow \frac{V_1 A}{v_1} = \frac{V_2 A}{v_2}$$

$$V_2 = \frac{v_2}{v_1} V_1 = \frac{0.8501}{0.8939} (120 \text{ m/min}) = \mathbf{114 \text{ m/min}}$$

14-87 Problem 14-86 is reconsidered. A general solution of the problem in which the input variables may be supplied and parametric studies performed is to be developed and the process is to be shown in the psychrometric chart for each set of input variables.

Analysis The problem is solved using EES, and the solution is given below.

14-88 Air is cooled by passing it over a cooling coil. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The dew point temperature of the incoming air stream at 35°C is

$$\begin{aligned} P_{v1} &= \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 32^\circ\text{C} \\ &= (0.7)(4.76 \text{ kPa}) = 3.332 \text{ kPa} \\ T_{dp} &= T_{\text{sat}} @ P_v = T_{\text{sat}} @ 3.332 \text{ kPa} = 25.8^\circ\text{C} \end{aligned}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. Then the properties of the air at both states are determined to be

$$\begin{aligned} P_{a1} &= P_1 - P_{v1} = 95 - 3.332 = 91.67 \text{ kPa} \\ \nu_1 &= \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(305 \text{ K})}{91.67 \text{ kPa}} = 0.9549 \text{ m}^3 / \text{kg dry air} \\ \omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(3.332 \text{ kPa})}{(95 - 3.332) \text{ kPa}} = 0.02261 \text{ kg H}_2\text{O/kg dry air} \\ h_1 &= c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(32^\circ\text{C}) + (0.02261)(2559.2 \text{ kJ/kg}) \\ &= 90.01 \text{ kJ/kg dry air} \end{aligned}$$

and

$$\begin{aligned} P_{v2} &= \phi_2 P_{g2} = (1.00)P_{\text{sat}} @ 20^\circ\text{C} = 2.339 \text{ kPa} \\ \nu_2 &= \frac{R_a T_2}{P_{a2}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{(95 - 2.339) \text{ kPa}} = 0.9075 \text{ m}^3 / \text{kg dry air} \\ \omega_2 &= \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(2.339 \text{ kPa})}{(95 - 2.339) \text{ kPa}} = 0.0157 \text{ kg H}_2\text{O/kg dry air} \\ h_2 &= c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0157)(2537.4 \text{ kJ/kg}) \\ &= 59.94 \text{ kJ/kg dry air} \end{aligned}$$

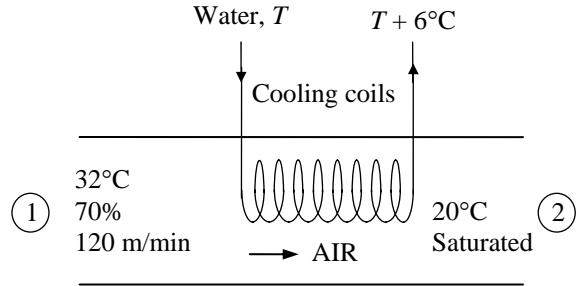

Also,

$$h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg} \quad (\text{Table A-4})$$

Then,

$$\begin{aligned} \dot{V}_1 &= V_1 A_1 = V_1 \frac{\pi D^2}{4} = (120 \text{ m/min}) \left(\frac{\pi(0.4 \text{ m})^2}{4} \right) = 15.08 \text{ m}^3 / \text{min} \\ \dot{m}_{a1} &= \frac{\dot{V}_1}{\nu_1} = \frac{15.08 \text{ m}^3 / \text{min}}{0.9549 \text{ m}^3 / \text{kg dry air}} = 15.79 \text{ kg/min} \end{aligned}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section (excluding the water),

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (15.79 \text{ kg/min})(0.02261 - 0.0157) = 0.1090 \text{ kg/min}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{no (steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{\text{out}} \rightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (15.79 \text{ kg/min})(90.01 - 59.94) \text{ kJ/kg} - (0.1090 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{465.7 \text{ kJ/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{\text{cooling water}} = \dot{m}_{\text{cooling water}} \Delta h = \dot{m}_{\text{cooling water}} c_p \Delta T$$

$$\dot{m}_{\text{cooling water}} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{465.7 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(6^\circ\text{C})} = \mathbf{18.57 \text{ kg/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{v_1} = \frac{\dot{V}_2}{v_2} \longrightarrow \frac{V_1 A}{v_1} = \frac{V_2 A}{v_2}$$

$$V_2 = \frac{v_2}{v_1} V_1 = \frac{0.9075}{0.9549} (120 \text{ m/min}) = \mathbf{114 \text{ m/min}}$$

14-89 Air flows through an air conditioner unit. The inlet and exit states are specified. The rate of heat transfer and the mass flow rate of condensate water are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The inlet state of the air is completely specified, and the total pressure is 98 kPa. The properties of the air at the inlet state may be determined from (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 77.88 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01866 \text{ kg H}_2\text{O/kg dry air}$$

$$\phi_1 = 0.6721$$

The partial pressure of water vapor at the exit state is

$$P_{v2} = P_{\text{sat}@ 6.5^\circ\text{C}} = 0.9682 \text{ kPa} \quad (\text{Table A - 4})$$

The saturation pressure at the exit state is

$$P_{g2} = P_{\text{sat}@ 25^\circ\text{C}} = 3.17 \text{ kPa} \quad (\text{Table A - 4})$$

Then, the relative humidity at the exit state becomes

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{0.9682}{3.17} = 0.3054$$

Now, the exit state is also fixed. The properties are obtained from EES to be

$$h_2 = 40.97 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.006206 \text{ kg H}_2\text{O/kg dry air}$$

$$v_2 = 0.8820 \text{ m}^3/\text{kg}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_2}{v_2} = \frac{1000 \text{ m}^3/\text{min}}{0.8820 \text{ m}^3/\text{kg}} = 1133.8 \text{ kg/min}$$

The mass flow rate of condensate water is

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (1133.8 \text{ kg/min})(0.01866 - 0.006206) = 14.12 \text{ kg/min} = \mathbf{847.2 \text{ kg/h}}$$

The enthalpy of condensate water is

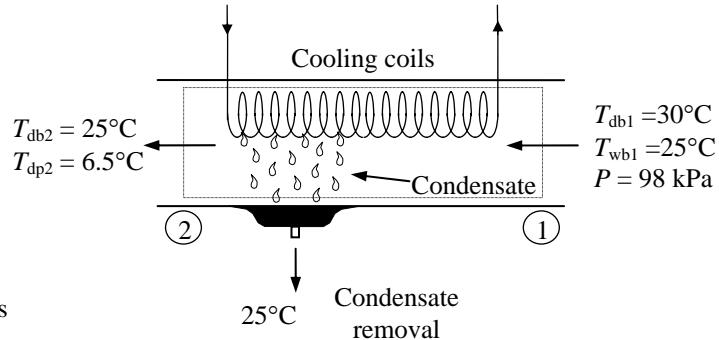

$$h_{w2} = h_f@ 25^\circ\text{C} = 104.83 \text{ kJ/kg} \quad (\text{Table A - 4})$$

An energy balance on the control volume gives

$$\dot{m}_a h_1 = \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2}$$

$$(1133.8 \text{ kg/min})(77.88 \text{ kJ/kg}) = \dot{Q}_{\text{out}} + (1133.8 \text{ kg/min})(40.97 \text{ kJ/kg}) + (14.12 \text{ kg/min})(104.83 \text{ kJ/kg})$$

$$\dot{Q}_{\text{out}} = 40,377 \text{ kJ/min} = \mathbf{672.9 \text{ kW}}$$

14-90 Atmospheric air enters the evaporator of an automobile air conditioner at a specified pressure, temperature, and relative humidity. The dew point and wet bulb temperatures at the inlet to the evaporator section, the required heat transfer rate from the atmospheric air to the evaporator fluid, and the rate of condensation of water vapor in the evaporator section are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$T_{dp1} = 15.7^\circ\text{C}$$

$$T_{wb1} = 19.5^\circ\text{C}$$

$$h_1 = 55.60 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01115 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.8655 \text{ m}^3 / \text{kg dry air}$$

$$h_2 = 27.35 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00686 \text{ kg H}_2\text{O/kg dry air}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{V_{car} ACH}{v_1} = \frac{(2 \text{ m}^3/\text{change})(5 \text{ changes/min})}{0.8655 \text{ m}^3} = 11.55 \text{ kg/min}$$

The mass flow rates of vapor at the inlet and exit are

$$\dot{m}_{v1} = \omega_1 \dot{m}_a = (0.01115)(11.55 \text{ kg/min}) = 0.1288 \text{ kg/min}$$

$$\dot{m}_{v2} = \omega_2 \dot{m}_a = (0.00686)(11.55 \text{ kg/min}) = 0.07926 \text{ kg/min}$$

An energy balance on the control volume gives

$$\dot{m}_a h_1 = \dot{Q}_{out} + \dot{m}_a h_2 + \dot{m}_w h_{w2}$$

where the the enthalpy of condensate water is

$$h_{w2} = h_{f@10^\circ\text{C}} = 42.02 \text{ kJ/kg} \quad (\text{Table A - 4})$$

and the rate of condensation of water vapor is

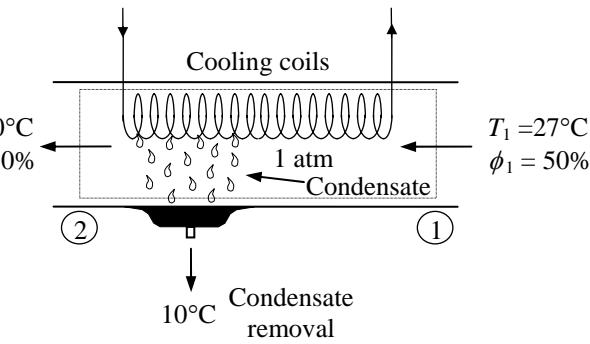

$$\dot{m}_w = \dot{m}_{v1} - \dot{m}_{v2} = 0.1288 - 0.07926 = \mathbf{0.0495 \text{ kg/min}}$$

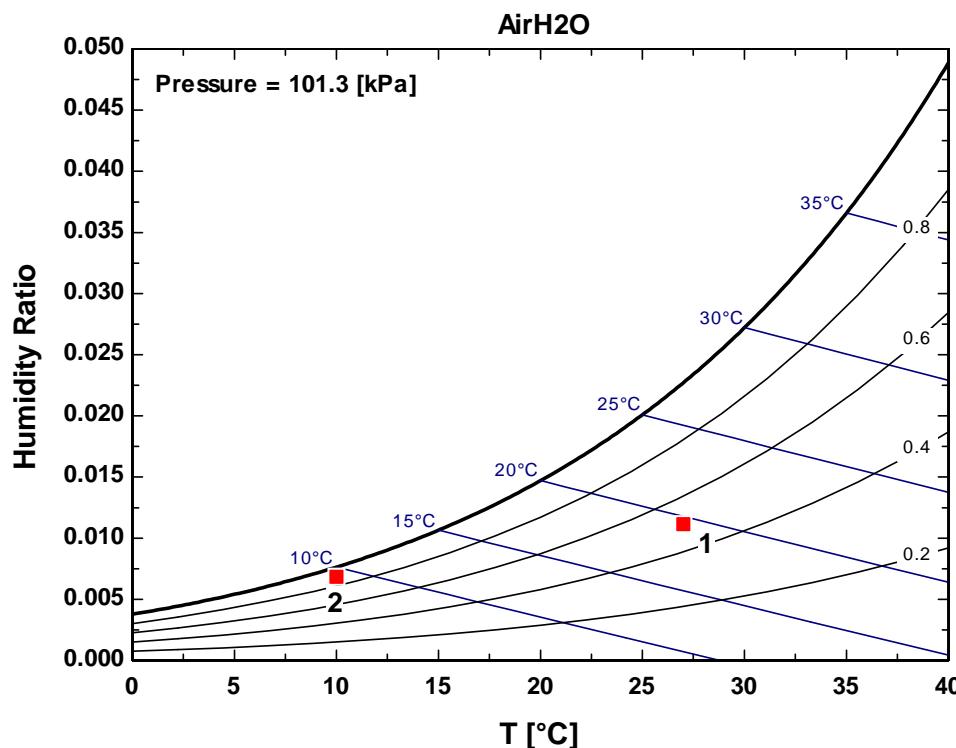

Substituting,

$$\dot{m}_a h_1 = \dot{Q}_{out} + \dot{m}_a h_2 + \dot{m}_w h_{w2}$$

$$(11.55 \text{ kg/min})(55.60 \text{ kJ/kg}) = \dot{Q}_{out} + (11.55 \text{ kg/min})(27.35 \text{ kJ/kg}) + (0.0495 \text{ kg/min})(42.02 \text{ kJ/kg})$$

$$\dot{Q}_{out} = 324.4 \text{ kJ/min} = \mathbf{5.41 \text{ kW}}$$

Discussion We could not show the process line between the states 1 and 2 because we do not know the process path.

14-91 Atmospheric air flows into an air conditioner that uses chilled water as the cooling fluid. The mass flow rate of the condensate water and the volume flow rate of chilled water supplied to the air conditioner are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis We may assume that the exit relative humidity is 100 percent since the exit temperature (18°C) is below the dew-point temperature of the inlet air (25°C). The properties of the air at the exit state may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$h_2 = 51.34 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.01311 \text{ kg H}_2\text{O/kg dry air}$$

The partial pressure of water vapor at the inlet state is (Table A-4)

$$P_{v1} = P_{\text{sat}} @ 25^\circ\text{C} = 3.17 \text{ kPa}$$

The saturation pressure at the inlet state is

$$P_{g1} = P_{\text{sat}} @ 28^\circ\text{C} = 3.783 \text{ kPa} \text{ (Table A - 4)}$$

Then, the relative humidity at the inlet state becomes

$$\phi_1 = \frac{P_{v1}}{P_{g1}} = \frac{3.17}{3.783} = 0.8379$$

Now, the inlet state is also fixed. The properties are obtained from EES to be

$$h_1 = 80.14 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.02036 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.8927 \text{ m}^3/\text{kg}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{(2000 / 60) \text{ m}^3/\text{h}}{0.8927 \text{ m}^3/\text{kg}} = 37.34 \text{ kg/min}$$

The mass flow rate of condensate water is

$$\begin{aligned} \dot{m}_w &= \dot{m}_a (\omega_1 - \omega_2) \\ &= (37.34 \text{ kg/min})(0.02036 - 0.01311) \\ &= 0.2707 \text{ kg/min} \\ &= \mathbf{16.24 \text{ kg/h}} \end{aligned}$$

The enthalpy of condensate water is

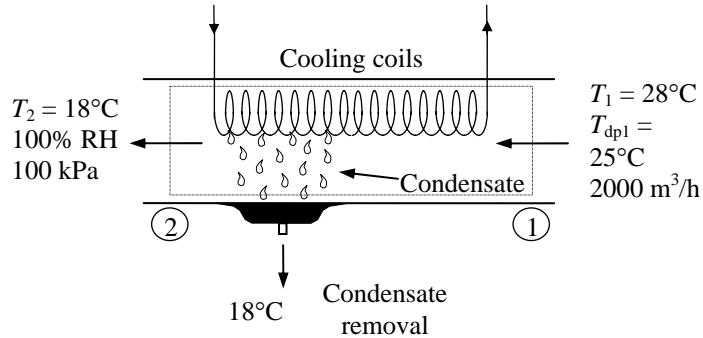

$$h_{w2} = h_f @ 18^\circ\text{C} = 75.54 \text{ kJ/kg} \text{ (Table A - 4)}$$

An energy balance on the control volume gives

$$\begin{aligned} \dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (37.34 \text{ kg/min})(80.14 \text{ kJ/kg}) &= \dot{Q}_{\text{out}} + (37.34 \text{ kg/min})(51.34 \text{ kJ/kg}) + (0.2707 \text{ kg/min})(75.54 \text{ kJ/kg}) \\ \dot{Q}_{\text{out}} &= 1055 \text{ kJ/min} = 17.59 \text{ kW} \end{aligned}$$

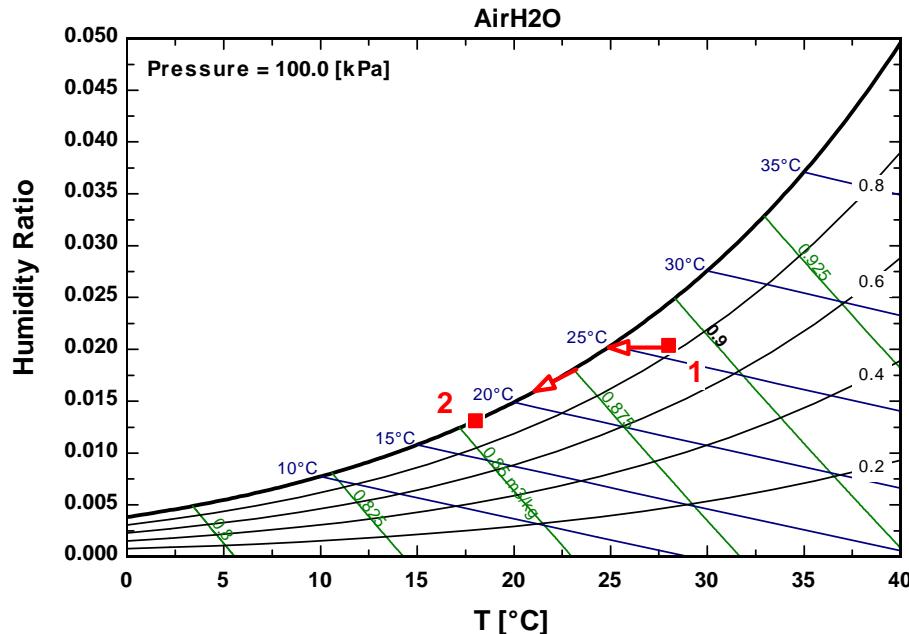

Noting that the rate of heat lost from the air is received by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{\text{in}} = \dot{m}_{cw} c_p \Delta T_{cw} \longrightarrow \dot{m}_{cw} = \frac{\dot{Q}_{\text{in}}}{c_p \Delta T_{cw}} = \frac{1055 \text{ kJ/min}}{(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(10^\circ\text{C})} = 25.24 \text{ kg/min}$$

where we used the specific heat of water value at room temperature. Assuming a density of 1000 kg/m^3 for water, the volume flow rate is determined to be

$$\dot{V}_{cw} = \frac{\dot{m}_{cw}}{\rho_{cw}} = \frac{25.24 \text{ kg/min}}{1000 \text{ kg/m}^3} = \mathbf{0.0252 \text{ m}^3/\text{min}}$$

14-92 An automobile air conditioner using refrigerant 134a as the cooling fluid is considered. The inlet and exit states of moist air in the evaporator are specified. The volume flow rate of the air entering the evaporator of the air conditioner is to be determined.

Assumptions 1 All processes are steady flow and the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Analysis We assume that the total pressure of moist air is 100 kPa. Then, the inlet and exit states of the moist air for the evaporator are completely specified. The properties may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 55.88 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01206 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.8724 \text{ m}^3/\text{kg dry air}$$

$$h_2 = 23.31 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.006064 \text{ kg H}_2\text{O/kg dry air}$$

The mass flow rate of dry air is given by

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{\dot{V}_1}{0.8724 \text{ m}^3/\text{kg}}$$

The mass flow rate of condensate water is expressed as

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = \frac{\dot{V}_1}{0.8724} (0.01206 - 0.006064) = 0.006873 \dot{V}_1$$

The enthalpy of condensate water is

$$h_{w2} = h_f @ 8^\circ\text{C} = 33.63 \text{ kJ/kg} \quad (\text{Table A - 4})$$

An energy balance on the control volume gives

$$\begin{aligned} \dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ \frac{\dot{V}_1}{0.8724} (55.88) &= \dot{Q}_{\text{out}} + \frac{\dot{V}_1}{0.8724} (23.11) + 0.006873 \dot{V}_1 (33.63) \end{aligned} \quad (1)$$

The properties of the R-134a at the inlet of the compressor and the enthalpy at the exit for the isentropic process are (R-134a tables)

$$\begin{aligned} P_{R1} &= 200 \text{ kPa} & h_{R1} &= 244.46 \text{ kJ/kg} \\ x_{R1} &= 1 & s_{R1} &= 0.9377 \text{ kJ/kg.K} \\ P_{R2} &= 1600 \text{ kPa} & h_{R2,s} &= 287.87 \text{ kJ/kg} \\ s_{R2} &= s_{R1} \end{aligned}$$

The enthalpies of R-134a at the condenser exit and the throttle exit are

$$h_{R3} = h_f @ 1600 \text{ kPa} = 135.93 \text{ kJ/kg}$$

$$h_{R4} = h_{R3} = 135.93 \text{ kJ/kg}$$

The mass flow rate of the refrigerant can be determined from the expression for the compressor power:

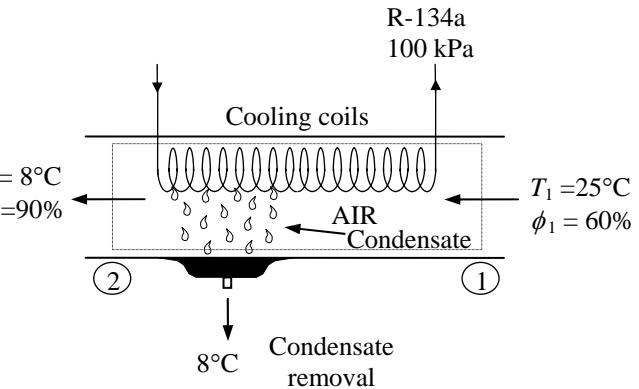

$$\begin{aligned} \dot{W}_C &= \dot{m}_R \frac{h_{R2,s} - h_{R1}}{\eta_C} \\ 6 \text{ kW} &= \dot{m}_R \frac{(287.87 - 244.46) \text{ kJ/kg}}{0.85} \longrightarrow \dot{m}_R = 0.1175 \text{ kg/s} = 7.049 \text{ kg/min} \end{aligned}$$

The rate of heat absorbed by the R-134a in the evaporator is

$$\dot{Q}_{R,\text{in}} = \dot{m}_R (h_{R1} - h_{R4}) = (7.049 \text{ kg/min})(244.46 - 135.93) \text{ kJ/kg} = 765.0 \text{ kJ/min}$$

The rate of heat lost from the air in the evaporator is absorbed by the refrigerant-134a. That is, $\dot{Q}_{R,\text{in}} = \dot{Q}_{\text{out}}$. Then, the volume flow rate of the air at the inlet of the evaporator can be determined from Eq. (1) to be

$$\frac{\dot{V}_1}{0.8724} (55.88) = 765.0 + \frac{\dot{V}_1}{0.8724} (23.11) + 0.006873 \dot{V}_1 (33.63) \longrightarrow \dot{V}_1 = 20.62 \text{ m}^3/\text{min}$$

14-93 Air is cooled and dehumidified at constant pressure. The cooling required is provided by a simple ideal vapor-compression refrigeration system using refrigerant-134a as the working fluid. The exergy destruction in the total system per 1000 m³ of dry air is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 106.8 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0292 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.905 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 52.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0112 \text{ kg H}_2\text{O/kg dry air}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit. Then, from Table A-4,

$$h_w \equiv h_f @ 28^\circ\text{C} = 117.4 \text{ kJ/kg}$$

Analysis The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The mass of air is

$$m_a = \frac{V_1}{v_1} = \frac{1000 \text{ m}^3}{0.905 \text{ m}^3/\text{kg dry air}} = 1105 \text{ kg}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$m_w = m_a(\omega_1 - \omega_2) = (1105 \text{ kg})(0.0292 - 0.0112) = 19.89 \text{ kg}$$

Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \xrightarrow{\text{sh0 (steady)}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = m_a(h_1 - h_2) - m_w h_w$$

$$\dot{Q}_{out} = (1105 \text{ kg})(106.8 - 52.7) \text{ kJ/kg} - (19.89 \text{ kg})(117.4 \text{ kJ/kg}) = 57,450 \text{ kJ}$$

We obtain the properties for the vapor-compression refrigeration cycle as follows (Tables A-11, through A-13):

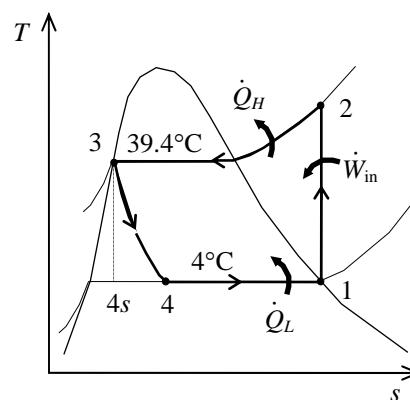

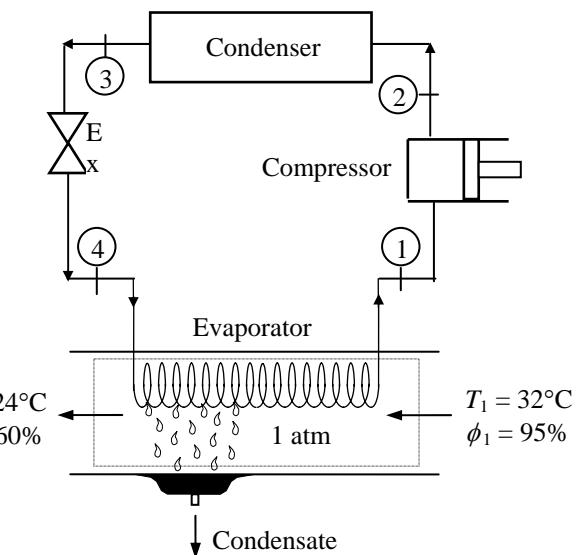

$$\left. \begin{array}{l} T_1 = 4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 4^\circ\text{C} = 252.77 \text{ kJ/kg} \\ s_1 = s_g @ 4^\circ\text{C} = 0.92927 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$\left. \begin{array}{l} P_2 = P_{\text{sat}} @ 39.4^\circ\text{C} = 1 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \left. \begin{array}{l} h_2 = 275.29 \text{ kJ/kg} \end{array} \right.$$

$$\left. \begin{array}{l} P_3 = 1 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \left. \begin{array}{l} h_3 = h_f @ 1 \text{ MPa} = 107.32 \text{ kJ/kg} \\ s_3 = s_f @ 1 \text{ MPa} = 0.39189 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$h_4 \cong h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_4 = 4^\circ\text{C} \\ h_4 = 107.32 \text{ kJ/kg} \end{array} \right\} \left. \begin{array}{l} x_4 = 0.2561 \\ s_4 = 0.4045 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

The mass flow rate of refrigerant-134a is

$$m_R = \frac{Q_L}{h_1 - h_4} = \frac{57,450 \text{ kJ}}{(252.77 - 107.32) \text{ kJ/kg}} = 395.0 \text{ kg}$$

The amount of heat rejected from the condenser is

$$Q_H = m_R(h_2 - h_3) = (395.0 \text{ kg})(275.29 - 107.32) \text{ kJ/kg} = 66,350 \text{ kJ}$$

Next, we calculate the exergy destruction in the components of the refrigeration cycle:

$$X_{\text{destroyed},12} = m_R T_0(s_2 - s_1) = 0 \quad (\text{since the process is isentropic})$$

$$\begin{aligned} X_{\text{destroyed},23} &= T_0 \left(m_R(s_3 - s_2) + \frac{Q_H}{T_H} \right) \\ &= (305 \text{ K}) \left((395 \text{ kg})(0.39189 - 0.92927) \text{ kJ/kg} \cdot \text{K} + \frac{66,350 \text{ kJ}}{305 \text{ K}} \right) = 1609 \text{ kJ} \end{aligned}$$

$$X_{\text{destroyed},34} = m_R T_0(s_4 - s_3) = (395 \text{ kg})(305 \text{ K})(0.4045 - 0.39189) \text{ kJ/kg} \cdot \text{K} = 1519 \text{ kJ}$$

The entropies of water vapor in the air stream are

$$s_{g1} = s_g @ 32^\circ\text{C} = 8.4114 \text{ kJ/kg} \cdot \text{K}$$

$$s_{g2} = s_g @ 24^\circ\text{C} = 8.5782 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of water vapor in the air stream is

$$\Delta S_{\text{vapor}} = m_a(\omega_2 s_{g2} - \omega_1 s_{g1}) = (1105)(0.0112 \times 8.5782 - 0.0292 \times 8.4114) = -165.2 \text{ kJ/K}$$

The entropy of water leaving the cooling section is

$$S_w = m_w s_f @ 28^\circ\text{C} = (19.89 \text{ kg})(0.4091 \text{ kJ/kg} \cdot \text{K}) = 8.14 \text{ kJ/K}$$

The partial pressures of water vapor and dry air for air streams are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 32^\circ\text{C}} = (0.95)(4.760 \text{ kPa}) = 4.522 \text{ kPa}$$

$$P_{al} = P_1 - P_{v1} = 101.325 - 4.522 = 96.80 \text{ kPa}$$

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat} @ 24^\circ\text{C}} = (0.60)(2.986 \text{ kPa}) = 1.792 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 101.325 - 1.792 = 99.53 \text{ kPa}$$

The entropy change of dry air is

$$\begin{aligned} \Delta S_a &= m_a(s_2 - s_1) = m_a \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{al}} \right) \\ &= (1105) \left[(1.005) \ln \frac{297}{305} - (0.287) \ln \frac{99.53}{96.80} \right] = -38.34 \text{ kJ/kg dry air} \end{aligned}$$

The entropy change of R-134a in the evaporator is

$$\Delta S_{R,41} = m_R(s_1 - s_4) = (395 \text{ kg})(0.92927 - 0.4045) = 207.3 \text{ kJ/K}$$

An entropy balance on the evaporator gives

$$S_{\text{gen, evaporator}} = \Delta S_{R,41} + \Delta S_{\text{vapor}} + \Delta S_a + S_w = 207.3 + (-165.2) + (-38.34) + 8.14 = 11.90 \text{ kJ/K}$$

Then, the exergy destruction in the evaporator is

$$X_{\text{dest}} = T_0 S_{\text{gen, evaporator}} = (305 \text{ K})(11.90 \text{ kJ/K}) = 3630 \text{ kJ}$$

Finally the total exergy destruction is

$$\begin{aligned} X_{\text{dest, total}} &= X_{\text{dest, compressor}} + X_{\text{dest, condenser}} + X_{\text{dest, throttle}} + X_{\text{dest, evaporator}} \\ &= 0 + 1609 + 1519 + 3630 \\ &= \mathbf{6758 \text{ kJ}} \end{aligned}$$

The greatest exergy destruction occurs in the evaporator. Note that heat is absorbed from humid air and rejected to the ambient air at 32°C (305 K), which is also taken as the dead state temperature.

Evaporative Cooling

14-94C Evaporative cooling is the cooling achieved when water evaporates in dry air. It will not work on humid climates.

14-95C During evaporation from a water body to air, the latent heat of vaporization will be equal to *convection* heat transfer from the air when *conduction* from the lower parts of the water body to the surface is negligible, and temperature of the surrounding surfaces is at about the temperature of the water surface so that the *radiation* heat transfer is negligible.

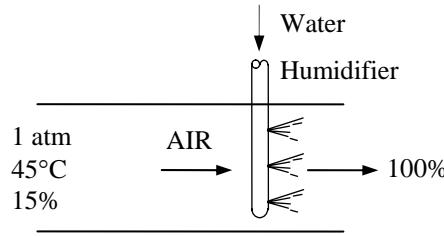

14-96C In steady operation, the mass transfer process does not have to involve heat transfer. However, a mass transfer process that involves phase change (evaporation, sublimation, condensation, melting etc.) must involve heat transfer. For example, the evaporation of water from a lake into air (mass transfer) requires the transfer of latent heat of water at a specified temperature to the liquid water at the surface (heat transfer).

14-97 Desert dwellers often wrap their heads with a water-soaked porous cloth. The temperature of this cloth on a desert with specified temperature and relative humidity is to be determined.

Analysis Since the cloth behaves as the wick on a wet bulb thermometer, the temperature of the cloth will become the wet-bulb temperature. According to the psychrometric chart, this temperature is

$$T_2 = T_{wb1} = \mathbf{23.3^\circ C}$$

This process can be represented by an evaporative cooling process as shown in the figure.

14-98 Air is cooled by an evaporative cooler. The exit temperature of the air and the required rate of water supply are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31) at 36°C and 20% relative humidity we read

$$T_{wb1} = 19.5^\circ\text{C}$$

$$\omega_1 = 0.0074 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.887 \text{ m}^3/\text{kg dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \approx T_{wb1} = 19.5^\circ\text{C}$$

At this wet-bulb temperature and 90% relative humidity we read

$$T_2 = 20.5^\circ\text{C}$$

$$\omega_2 = 0.0137 \text{ kg H}_2\text{O / kg dry air}$$

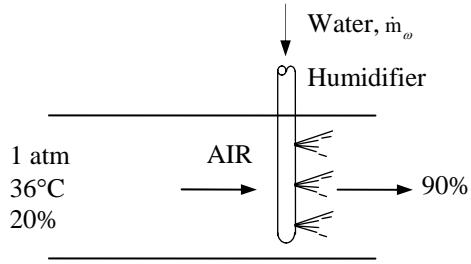

Thus air will be cooled to 20.5°C in this evaporative cooler.

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3 / \text{min}}{0.887 \text{ m}^3 / \text{kg dry air}} = 4.51 \text{ kg/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\begin{aligned}\dot{m}_{\text{supply}} &= \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a (\omega_2 - \omega_1) \\ &= (4.51 \text{ kg/min})(0.0137 - 0.0074) \\ &= \mathbf{0.028 \text{ kg/min}}\end{aligned}$$

14-99E Air is cooled by an evaporative cooler. The exit temperature of the air and the required rate of water supply are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31E or EES) at 100°F and 30% relative humidity we read

$$T_{wb1} = 74.3^{\circ}\text{F}$$

$$\omega_1 = 0.0123 \text{ lbm H}_2\text{O/lbm dry air}$$

$$v_1 = 14.4 \text{ ft}^3/\text{lbfm dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \cong T_{wb1} = 74.3^{\circ}\text{F}$$

At this wet-bulb temperature and 90% relative humidity we read

$$T_2 = 76.6^{\circ}\text{F}$$

$$\omega_2 = 0.0178 \text{ lbm H}_2\text{O/lbm dry air}$$

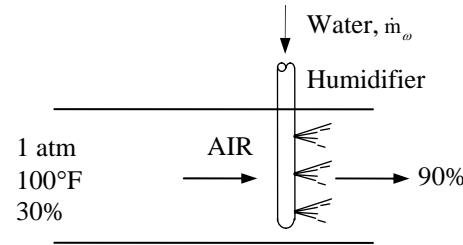

Thus air will be cooled to 76.6°F in this evaporative cooler.

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{200 \text{ ft}^3 / \text{min}}{14.4 \text{ ft}^3 / \text{lbfm dry air}} = 13.9 \text{ lbm/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\dot{m}_{\text{supply}} = \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a (\omega_2 - \omega_1) = (13.9 \text{ lbm/min})(0.0178 - 0.0123) = \mathbf{0.076 \text{ lbm/min}}$$

14-100 Air is cooled by an evaporative cooler. The final relative humidity and the amount of water added are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31) at 32°C and 30% relative humidity we read

$$T_{wb1} = 19.4^\circ\text{C}$$

$$\omega_1 = 0.0089 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.877 \text{ m}^3/\text{kg dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \approx T_{wb1} = 19.4^\circ\text{C}$$

At this wet-bulb temperature and 22°C temperature we read

$$\phi_2 = 79\%$$

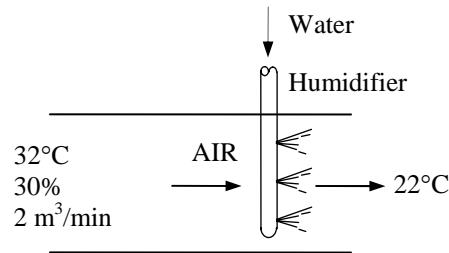

$$\omega_2 = 0.0130 \text{ kg H}_2\text{O/kg dry air}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}}{v_1} = \frac{5 \text{ m}^3 / \text{min}}{0.877 \text{ m}^3 / \text{kg dry air}} = 5.70 \text{ kg/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\dot{m}_{\text{supply}} = \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a (\omega_2 - \omega_1) = (5.70 \text{ kg/min})(0.0130 - 0.0089) = 0.0234 \text{ kg/min}$$

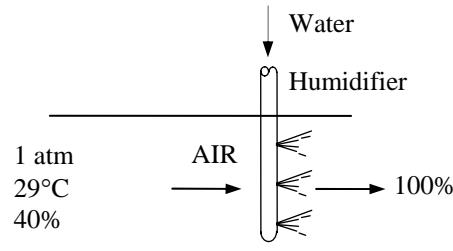

14-101 Air enters an evaporative cooler at a specified state and relative humidity. The lowest temperature that air can attain is to be determined.

Analysis From the psychrometric chart (Fig. A-31) at 29°C and 40% relative humidity we read

$$T_{wb1} = 19.3^\circ\text{C}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature, which is the lowest temperature that can be obtained in an evaporative cooler. That is,

$$T_{\min} = T_{wb1} = 19.3^\circ\text{C}$$

14-102 Air is first heated in a heating section and then passed through an evaporative cooler. The exit relative humidity and the amount of water added are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31 or EES) at 20°C and 50% relative humidity we read

$$\omega_1 = 0.00726 \text{ kg H}_2\text{O/kg dry air}$$

The specific humidity ω remains constant during the heating process. Therefore, $\omega_2 = \omega_1 = 0.00726 \text{ kg H}_2\text{O / kg dry air}$. At this ω value and 35°C we read $T_{wb2} = 19.1^\circ\text{C}$.

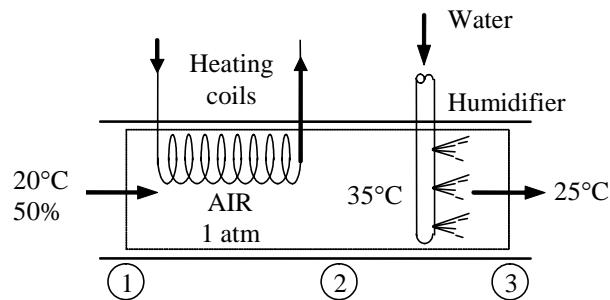

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is, $T_{wb3} \equiv T_{wb2} = 19.1^\circ\text{C}$. At this T_{wb} value and 25°C we read

$$\phi_3 = 57.5\%$$

$$\omega_3 = 0.0114 \text{ kg H}_2\text{O/kg dry air}$$

(b) The amount of water added to the air per unit mass of air is

$$\Delta\omega_{23} = \omega_3 - \omega_2 = 0.0114 - 0.00726 = \mathbf{0.00413 \text{ kg H}_2\text{O/kg dry air}}$$

Adiabatic Mixing of Airstreams

14-103C This will occur when the straight line connecting the states of the two streams on the psychrometric chart crosses the saturation line.

14-104C Yes.

14-105 Two airstreams are mixed steadily. The specific humidity, the relative humidity, the dry-bulb temperature, and the volume flow rate of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 62.7 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0119 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.882 \text{ m}^3/\text{kg dry air}$$

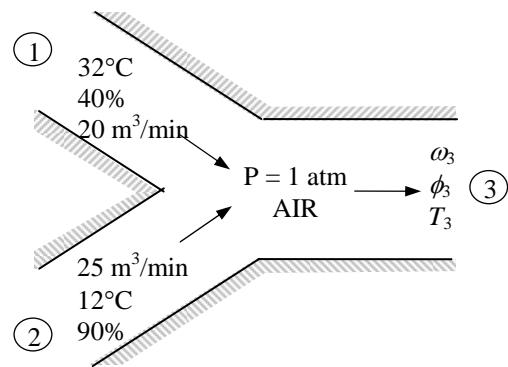

and

$$h_2 = 31.9 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0079 \text{ kg H}_2\text{O/kg dry air}$$

$$v_2 = 0.819 \text{ m}^3/\text{kg dry air}$$

Analysis The mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{20 \text{ m}^3/\text{min}}{0.882 \text{ m}^3/\text{kg dry air}} = 22.7 \text{ kg/min}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{v_2} = \frac{25 \text{ m}^3/\text{min}}{0.819 \text{ m}^3/\text{kg dry air}} = 30.5 \text{ kg/min}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (22.7 + 30.5) \text{ kg/min} = 53.2 \text{ kg/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{22.7}{30.5} = \frac{0.0079 - \omega_3}{\omega_3 - 0.0119} = \frac{31.9 - h_3}{h_3 - 62.7}$$

which yields,

$$\omega_3 = 0.0096 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = 45.0 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$T_3 = 20.6^\circ\text{C}$$

$$\phi_3 = 63.4\%$$

$$v_3 = 0.845 \text{ m}^3/\text{kg dry air}$$

Finally, the volume flow rate of the mixture is determined from

$$\dot{V}_3 = \dot{m}_{a3} v_3 = (53.2 \text{ kg/min})(0.845 \text{ m}^3/\text{kg}) = 45.0 \text{ m}^3/\text{min}$$

14-106 Two airstreams are mixed steadily. The specific humidity, the relative humidity, the dry-bulb temperature, and the volume flow rate of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Analysis The properties of each inlet stream are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 32^\circ\text{C} = (0.40)(4.760 \text{ kPa}) = 1.90 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 90 - 1.90 = 88.10 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(305 \text{ K})}{88.10 \text{ kPa}}$$

$$= 0.994 \text{ m}^3 / \text{kg dry air}$$

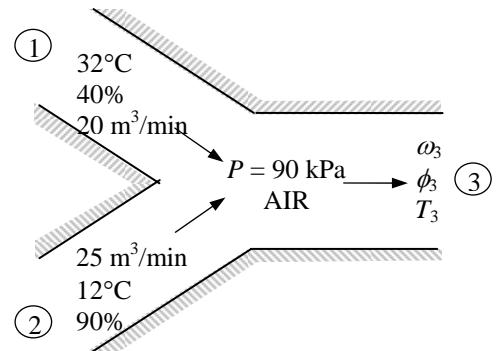

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.90 \text{ kPa})}{(90 - 1.90) \text{ kPa}}$$

$$= 0.0134 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1}$$

$$= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(32^\circ\text{C}) + (0.0134)(2559.2 \text{ kJ/kg})$$

$$= 66.45 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}} @ 12^\circ\text{C} = (0.90)(1.403 \text{ kPa}) = 1.26 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 90 - 1.26 = 88.74 \text{ kPa}$$

$$\nu_2 = \frac{R_a T_2}{P_{a2}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(285 \text{ K})}{88.74 \text{ kPa}} = 0.922 \text{ m}^3 / \text{kg dry air}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(1.26 \text{ kPa})}{(90 - 1.26) \text{ kPa}} = 0.00883 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(12^\circ\text{C}) + (0.00883)(2522.9 \text{ kJ/kg}) = 34.34 \text{ kJ/kg dry air}$$

Then the mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{20 \text{ m}^3 / \text{min}}{0.994 \text{ m}^3 / \text{kg dry air}} = 20.12 \text{ kg/min}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{\nu_2} = \frac{25 \text{ m}^3 / \text{min}}{0.922 \text{ m}^3 / \text{kg dry air}} = 27.11 \text{ kg/min}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (20.12 + 27.11) \text{ kg/min} = 47.23 \text{ kg/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \longrightarrow \frac{20.12}{27.11} = \frac{0.00883 - \omega_3}{\omega_3 - 0.0134} = \frac{34.34 - h_3}{h_3 - 66.45}$$

which yields

$$\omega_3 = \mathbf{0.0108 \text{ kg H}_2\text{O/kg dry air}}$$

$$h_3 = 48.02 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties are determined from

$$h_3 = c_p T_3 + \omega_3 h_{g3} \cong c_p T_3 + \omega_3 (2501.3 + 1.82 T_3)$$

$$48.02 \text{ kJ/kg} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})T_3 + (0.0108)(2500.9 + 1.82 T_3) \text{ kJ/kg} \longrightarrow T_3 = \mathbf{20.5^\circ\text{C}}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}}$$

$$0.0108 = \frac{0.622 P_{v3}}{90 - P_{v3}} \longrightarrow P_{v3} = 1.54 \text{ kPa}$$

$$\phi_3 = \frac{P_{v3}}{P_{g3}} = \frac{P_{v3}}{P_{\text{sat at } T_3}} = \frac{1.54 \text{ kPa}}{2.41 \text{ kPa}} = 0.639 \text{ or } \mathbf{63.9\%}$$

Finally,

$$P_{a3} = P_3 - P_{v3} = 90 - 1.54 = 88.46 \text{ kPa}$$

$$\nu_3 = \frac{R_a T_3}{P_{a3}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293.5 \text{ K})}{88.46 \text{ kPa}} = 0.952 \text{ m}^3/\text{kg dry air}$$

$$\dot{V}_3 = \dot{m}_{a3} \nu_3 = (47.23 \text{ kg/min})(0.952 \text{ m}^3 / \text{kg}) = \mathbf{45.0 \text{ m}^3/\text{min}}$$

14-107 A stream of warm air is mixed with a stream of saturated cool air. The temperature, the specific humidity, and the relative humidity of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties The properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$h_1 = 99.4 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0246 \text{ kg H}_2\text{O/kg dry air}$$

and

$$h_2 = 34.1 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00873 \text{ kg H}_2\text{O/kg dry air}$$

Analysis The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\begin{aligned} \frac{\dot{m}_{a1}}{\dot{m}_{a2}} &= \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \\ \frac{8}{10} &= \frac{0.00873 - \omega_3}{\omega_3 - 0.0246} = \frac{34.1 - h_3}{h_3 - 99.4} \end{aligned}$$

which yields,

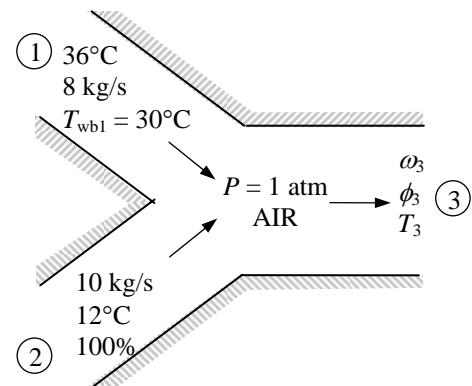

$$(b) \quad \omega_3 = \mathbf{0.0158 \text{ kg H}_2\text{O/kg dry air}}$$

$$h_3 = 63.1 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$(a) \quad T_3 = \mathbf{22.8^\circ\text{C}}$$

$$(c) \quad \phi_3 = \mathbf{90.1\%}$$

14-108 Problem 14-107 is reconsidered. The effect of the mass flow rate of saturated cool air stream on the mixture temperature, specific humidity, and relative humidity is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

```
P=101.325 [kPa]
Tdb[1] =36 [C]
Twb[1] =30 [C]
m_dot[1] = 8 [kg/s]

14-109E Two airstreams are mixed steadily. The mass flow ratio of the two streams for a specified mixture relative humidity and the relative humidity of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31E or from EES) to be

$$h_1 = 20.3 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0076 \text{ lbm H}_2\text{O/lbm dry air}$$

and

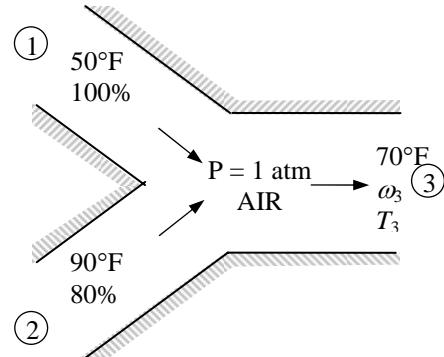

$$h_2 = 48.7 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0246 \text{ lbm H}_2\text{O/lbm dry air}$$

Analysis An application of Eq. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams gives

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{0.0246 - \omega_3}{\omega_3 - 0.0076} = \frac{48.7 - h_3}{h_3 - 20.3}$$

This equation cannot be solved directly. An iterative solution is needed. A mixture relative humidity ϕ_3 is selected. At this relative humidity and the given temperature (70°F), specific humidity and enthalpy are read from the psychrometric chart. These values are substituted into the above equation. If the equation is not satisfied, a new value of ϕ_3 is selected. This procedure is repeated until the equation is satisfied. Alternatively, EES software can be used. We used the following EES program to get these results:

$$\phi_3 = 100\%$$

$$\omega_3 = 0.0158 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_3 = 34.0 \text{ Btu/lbm dry air}$$

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = 1.07$$

"Given"

$$P=14.696 \text{ [psia]}$$

14-110 Two airstreams are mixed steadily. The temperature and the relative humidity of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or from EES) to be

$$h_1 = 88.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0187 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.914 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 36.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0085 \text{ kg H}_2\text{O/kg dry air}$$

$$v_2 = 0.828 \text{ m}^3/\text{kg dry air}$$

Analysis The mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{0.003 \text{ m}^3/\text{s}}{0.914 \text{ m}^3/\text{kg dry air}} = 0.003282 \text{ kg/s}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{v_2} = \frac{0.001 \text{ m}^3/\text{s}}{0.828 \text{ m}^3/\text{kg dry air}} = 0.001208 \text{ kg/s}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (0.003282 + 0.001208) \text{ kg/s} = 0.00449 \text{ kg/s}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\begin{aligned} \frac{\dot{m}_{a1}}{\dot{m}_{a2}} &= \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \\ \frac{0.003282}{0.001208} &= \frac{0.0085 - \omega_3}{\omega_3 - 0.0187} = \frac{36.7 - h_3}{h_3 - 88.5} \end{aligned}$$

which yields

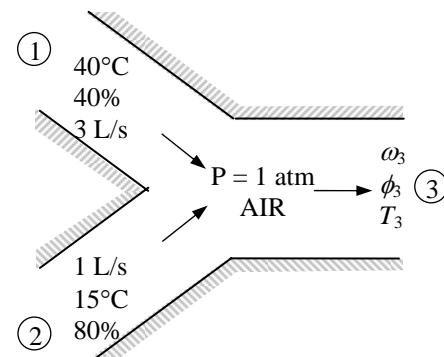

$$\omega_3 = 0.0160 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = 74.6 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$T_3 = 33.4^\circ\text{C}$$

$$\phi_3 = 0.493 = 49.3\%$$

14-111 Two airstreams are mixed steadily. The rate of exergy destruction is to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or from EES) to be

$$h_1 = 88.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0187 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.914 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 36.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0085 \text{ kg H}_2\text{O/kg dry air}$$

$$v_2 = 0.828 \text{ m}^3/\text{kg dry air}$$

The entropies of water vapor in the air streams are

$$s_{g1} = s_g @ 40^\circ\text{C} = 8.2556 \text{ kJ/kg} \cdot \text{K}$$

$$s_{g2} = s_g @ 15^\circ\text{C} = 8.7803 \text{ kJ/kg} \cdot \text{K}$$

Analysis The mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{0.003 \text{ m}^3/\text{s}}{0.914 \text{ m}^3/\text{kg dry air}} = 0.003282 \text{ kg/s}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{v_2} = \frac{0.001 \text{ m}^3/\text{s}}{0.828 \text{ m}^3/\text{kg dry air}} = 0.001208 \text{ kg/s}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = (0.003282 + 0.001208) \text{ kg/s} = 0.00449 \text{ kg/s}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\begin{aligned} \frac{\dot{m}_{a1}}{\dot{m}_{a2}} &= \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \\ \frac{0.003282}{0.001208} &= \frac{0.0085 - \omega_3}{\omega_3 - 0.0187} = \frac{36.7 - h_3}{h_3 - 88.5} \end{aligned}$$

which yields

$$\omega_3 = 0.0160 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = 74.6 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

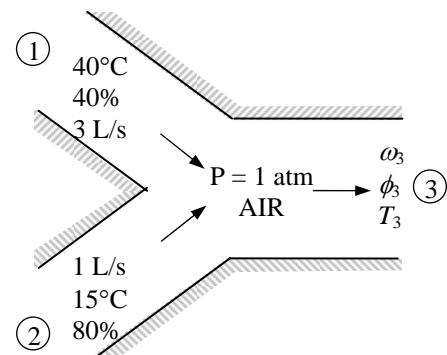

$$T_3 = 33.4^\circ\text{C}$$

$$\phi_3 = 0.493$$

The entropy of water vapor in the mixture is

$$s_{g3} = s_g @ 33.4^\circ\text{C} = 8.3833 \text{ kJ/kg} \cdot \text{K}$$

An entropy balance on the mixing chamber for the water gives

$$\begin{aligned}\Delta\dot{S}_w &= \dot{m}_{a3}\omega_3s_3 - \dot{m}_{a1}\omega_1s_1 - \dot{m}_{a2}\omega_2s_2 \\ &= 0.00449 \times 0.0160 \times 8.3833 - 0.003282 \times 0.0187 \times 8.2556 - 0.001208 \times 0.0085 \times 8.7803 \\ &= 5.426 \times 10^{-6} \text{ kW/K}\end{aligned}$$

The partial pressures of water vapor and dry air for all three air streams are

$$\begin{aligned}P_{v1} &= \phi_1 P_{g1} = \phi_1 P_{\text{sat at } 40^\circ\text{C}} = (0.40)(7.3851 \text{ kPa}) = 2.954 \text{ kPa} \\ P_{a1} &= P_1 - P_{v1} = 101.325 - 2.954 = 98.37 \text{ kPa} \\ P_{v2} &= \phi_2 P_{g2} = \phi_2 P_{\text{sat at } 15^\circ\text{C}} = (0.80)(1.7057 \text{ kPa}) = 1.365 \text{ kPa} \\ P_{a2} &= P_2 - P_{v2} = 101.325 - 1.365 = 99.96 \text{ kPa} \\ P_{v3} &= \phi_3 P_{g3} = \phi_3 P_{\text{sat at } 33.4^\circ\text{C}} = (0.493)(5.150 \text{ kPa}) = 2.539 \text{ kPa} \\ P_{a3} &= P_3 - P_{v3} = 101.325 - 2.539 = 98.79 \text{ kPa}\end{aligned}$$

An entropy balance on the mixing chamber for the dry air gives

$$\begin{aligned}\Delta\dot{S}_a &= \dot{m}_{a1}(s_3 - s_1) + \dot{m}_{a2}(s_3 - s_2) \\ &= \dot{m}_{a1}\left(c_p \ln \frac{T_3}{T_1} - R \ln \frac{P_{a3}}{P_{a1}}\right) + \dot{m}_{a2}\left(c_p \ln \frac{T_3}{T_2} - R \ln \frac{P_{a3}}{P_{a2}}\right) \\ &= 0.003282 \left[(1.005) \ln \frac{306.4}{313} - (0.287) \ln \frac{98.79}{98.37} \right] + 0.001208 \left[(1.005) \ln \frac{306.4}{288} - (0.287) \ln \frac{98.79}{99.96} \right] \\ &= (0.003282)(-0.02264) + (0.001208)(0.06562) \\ &= 4.964 \times 10^{-6} \text{ kW/K}\end{aligned}$$

The rate of entropy generation is

$$\dot{S}_{\text{gen}} = \Delta\dot{S}_a + \Delta\dot{S}_w = 4.964 \times 10^{-6} + 5.426 \times 10^{-6} = 10.39 \times 10^{-6} \text{ kW/K}$$

Finally, the rate of exergy destruction is

$$\dot{X}_{\text{dest}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(10.39 \times 10^{-6} \text{ kW/K}) = \mathbf{0.0031 \text{ kW}}$$

Wet Cooling Towers

14-112C The working principle of a natural draft cooling tower is based on buoyancy. The air in the tower has a high moisture content, and thus is lighter than the outside air. This light moist air rises under the influence of buoyancy, inducing flow through the tower.

14-113C A spray pond cools the warm water by spraying it into the open atmosphere. They require 25 to 50 times the area of a wet cooling tower for the same cooling load.

14-114 Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \quad \longrightarrow \quad \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}\end{aligned}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{no (steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3 h_3$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31 or EES),

$$h_1 = 44.7 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.008875 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.848 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 106.6 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.02905 \text{ kg H}_2\text{O/kg dry air}$$

From Table A-4,

$$h_3 \cong h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O}$$

Substituting,

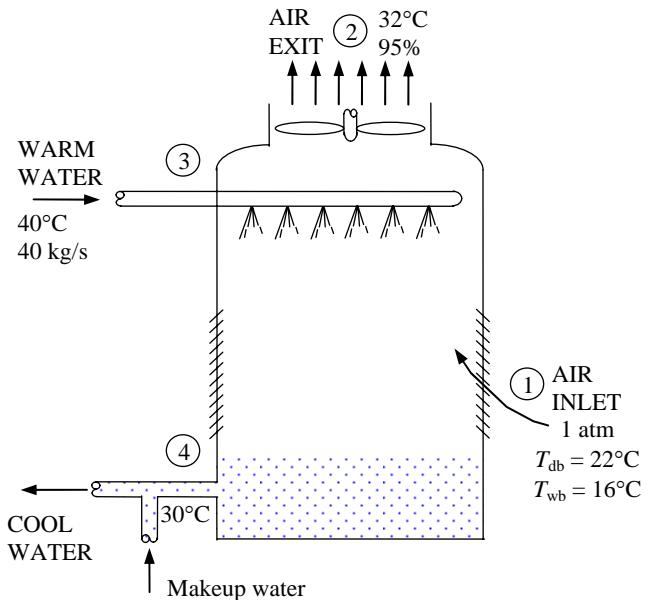

$$\dot{m}_a = \frac{(40 \text{ kg/s})(167.53 - 125.74) \text{ kJ/kg}}{(106.6 - 44.7) \text{ kJ/kg} - (0.02905 - 0.008875)(125.74) \text{ kJ/kg}} = 28.17 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (28.17 \text{ kg/s})(0.848 \text{ m}^3/\text{kg}) = 23.9 \text{ m}^3/\text{s}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (28.17 \text{ kg/s})(0.02905 - 0.008875) = 0.568 \text{ kg/s}$$

14-115 Water is cooled by air in a cooling tower. The relative humidity of the air at the exit and the water's exit temperature are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}\end{aligned}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{(0(steady))}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3 h_3$$

Solving for h_4 ,

$$h_4 = \frac{\dot{m}_3 h_3 - \dot{m}_a(h_2 - h_1)}{\dot{m}_3 - \dot{m}_{\text{makeup}}}$$

From the psychrometric chart (Fig. A-31),

$$h_1 = 20.4 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.00211 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.819 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 55.7 \text{ kJ/kg dry air}$$

$$\phi_2 = 1 = 100\%$$

From Table A-4,

$$h_3 \approx h_f @ 32^\circ\text{C} = 134.1 \text{ kJ/kg H}_2\text{O}$$

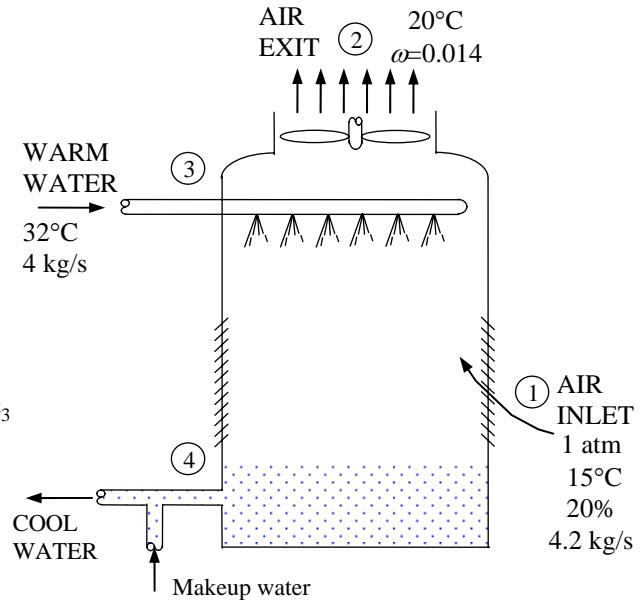

$$\text{Also, } \dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (4.2 \text{ kg/s})(0.014 - 0.00211) = 0.050 \text{ kg/s}$$

Substituting,

$$h_4 = \frac{\dot{m}_3 h_3 - \dot{m}_a(h_2 - h_1)}{\dot{m}_3 - \dot{m}_{\text{makeup}}} = \frac{(4)(134.1) - (0.12)(55.7 - 20.4)}{4 - 0.050} = 98.31 \text{ kJ/kg H}_2\text{O}$$

The exit temperature of the water is then (Table A-4)

$$T_4 = T_{\text{sat}} @ h_f = 98.31 \text{ kJ/kg} = 23.4^\circ\text{C}$$

14-116 Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e}$$

$$\dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2$$

$$\dot{m}_3 - \dot{m}_4 = \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{0(steady)}} = 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

The properties of air at the inlet and the exit are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 20^\circ\text{C}} = (0.70)(2.3392 \text{ kPa}) = 1.637 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 96 - 1.637 = 94.363 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{94.363 \text{ kPa}} = 0.891 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.637 \text{ kPa})}{(96 - 1.637) \text{ kPa}} = 0.0108 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0108)(2537.4 \text{ kJ/kg}) = 47.5 \text{ kJ/kg dry air}$$

and $P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat} @ 35^\circ\text{C}} = (1.00)(5.6291 \text{ kPa}) = 5.6291 \text{ kPa}$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(5.6291 \text{ kPa})}{(96 - 5.6291) \text{ kPa}} = 0.0387 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.0387)(2564.6 \text{ kJ/kg}) = 134.4 \text{ kJ/kg dry air}$$

From Table A-4,

$$h_3 \equiv h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \equiv h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O}$$

Substituting,

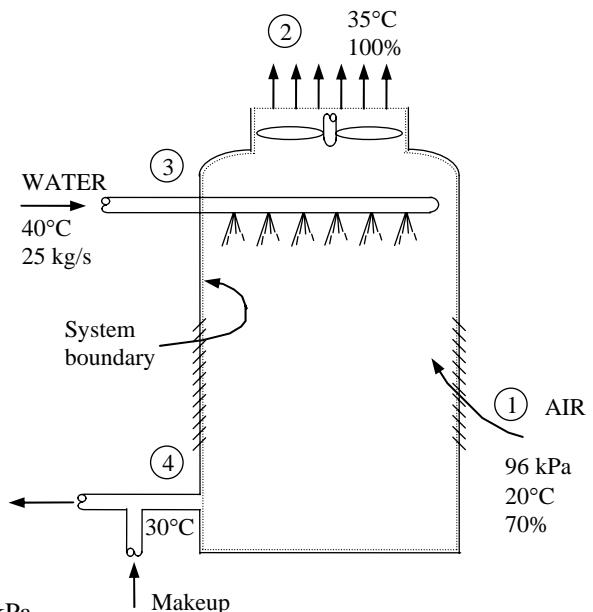

$$\dot{m}_a = \frac{(25 \text{ kg/s})(167.53 - 125.74) \text{ kJ/kg}}{(134.4 - 47.5) \text{ kJ/kg} - (0.0387 - 0.0108)(125.74) \text{ kJ/kg}} = 12.53 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (12.53 \text{ kg/s})(0.891 \text{ m}^3 / \text{kg}) = 11.2 \text{ m}^3 / \text{s}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (12.53 \text{ kg/s})(0.0387 - 0.0108) = 0.35 \text{ kg/s}$$

14-117 A natural-draft cooling tower is used to remove waste heat from the cooling water flowing through the condenser of a steam power plant. The mass flow rate of the cooling water, the volume flow rate of air into the cooling tower, and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 All processes are steady-flow and the mass flow rate of dry air remains constant during the entire process ($\dot{m}_a = \dot{m}_{a2} = \dot{m}_a$). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Analysis The inlet and exit states of the moist air for the tower are completely specified. The properties may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 50.74 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01085 \text{ kg H}_2\text{O/kg dry air}$$

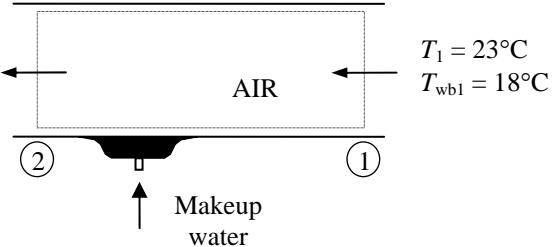

$$v_1 = 0.8536 \text{ m}^3/\text{kg dry air}$$

$$h_2 = 142.83 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.04112 \text{ kg H}_2\text{O/kg dry air}$$

$$T_2 = 37^\circ\text{C}$$

$$\phi_2 = 100\%$$

The enthalpies of cooling water at the inlet and exit of the condenser are (Table A-4)

$$h_{w3} = h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg}$$

$$h_{w4} = h_f @ 26^\circ\text{C} = 109.01 \text{ kJ/kg}$$

The steam properties for the condenser are (Steam tables)

$$\left. \begin{array}{l} P_{s1} = 200 \text{ kPa} \\ x_{s1} = 0 \end{array} \right\} h_{s1} = 504.71 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{s2} = 10 \text{ kPa} \\ s_{s2} = 7.962 \text{ kJ/kg.K} \end{array} \right\} h_{s2} = 2524.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{s3} = 10 \text{ kPa} \\ x_{s1} = 0 \end{array} \right\} h_{s3} = 191.81 \text{ kJ/kg}$$

The mass flow rate of dry air is given by

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{\dot{V}_1}{0.8536 \text{ m}^3/\text{kg}}$$

The mass flow rates of vapor at the inlet and exit of the cooling tower are

$$\dot{m}_{v1} = \omega_1 \dot{m}_a = (0.01085) \frac{\dot{V}_1}{0.8536} = 0.01271 \dot{V}_1$$

$$\dot{m}_{v2} = \omega_2 \dot{m}_a = (0.04112) \frac{\dot{V}_1}{0.8536} = 0.04817 \dot{V}_1$$

Mass and energy balances on the cooling tower give

$$\dot{m}_{v1} + \dot{m}_{cw3} = \dot{m}_{v2} + \dot{m}_{cw4}$$

$$\dot{m}_a h_1 + \dot{m}_{cw3} h_{w3} = \dot{m}_a h_2 + \dot{m}_{cw4} h_{w4}$$

The mass flow rate of the makeup water is determined from

$$\dot{m}_{makeup} = \dot{m}_{v2} - \dot{m}_{v1} = \dot{m}_{cw3} - \dot{m}_{cw4}$$

An energy balance on the condenser gives

$$0.18 \dot{m}_s h_{s1} + 0.82 \dot{m}_s h_{s2} + \dot{m}_{cw4} h_{w4} + \dot{m}_{makeup} h_{w4} = \dot{m}_s h_{s3} + \dot{m}_{cw3} h_{w3}$$

Solving all the above equations simultaneously with known and determined values using EES, we obtain

$$\dot{m}_{cw3} = 1413 \text{ kg/s}$$

$$\dot{V}_1 = 47,700 \text{ m}^3/\text{min}$$

$$\dot{m}_{makeup} = 28.19 \text{ kg/s}$$

14-118E Water is cooled by air in a cooling tower. The mass flow rate of dry air is to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}\end{aligned}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{0(steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3 h_3$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31E),

$$h_1 = 19.9 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.00391 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 13.31 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 34.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0149 \text{ lbm H}_2\text{O/lbm dry air}$$

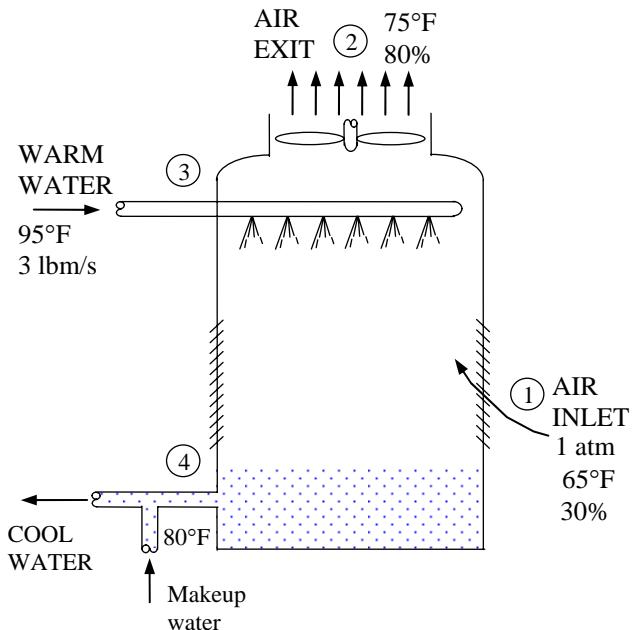

From Table A-4E,

$$h_3 \cong h_f @ 95^\circ\text{C} = 63.04 \text{ Btu/lbm H}_2\text{O}$$

$$h_4 \cong h_f @ 80^\circ\text{C} = 48.07 \text{ Btu/lbm H}_2\text{O}$$

Substituting,

$$\dot{m}_a = \frac{(3 \text{ lbm/s})(63.04 - 48.07) \text{ Btu/lbm}}{(34.3 - 19.9) \text{ Btu/lbm} - (0.0149 - 0.00391)(48.07) \text{ Btu/lbm}} = \mathbf{3.22 \text{ lbm/s}}$$

14-119E Water is cooled by air in a cooling tower. The exergy lost in the cooling tower is to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}\end{aligned}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{0(steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3 h_3$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31E),

$$h_1 = 19.9 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.00391 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 13.31 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 34.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0149 \text{ lbm H}_2\text{O/lbm dry air}$$

From Table A-4,

$$h_3 \cong h_f @ 95^\circ\text{F} = 63.04 \text{ Btu/lbm H}_2\text{O}$$

$$h_4 \cong h_f @ 80^\circ\text{F} = 48.07 \text{ Btu/lbm H}_2\text{O}$$

Substituting,

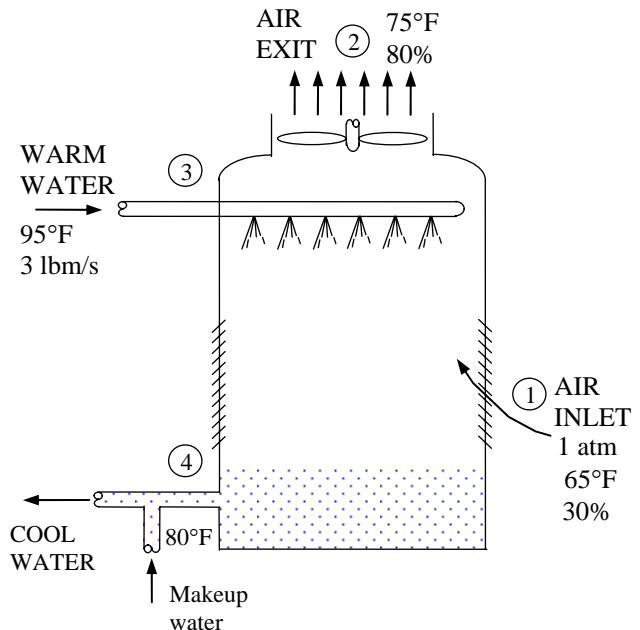

$$\dot{m}_a = \frac{(3 \text{ lbm/s})(63.04 - 48.07) \text{ Btu/lbm}}{(34.3 - 19.9) \text{ Btu/lbm} - (0.0149 - 0.00391)(48.07) \text{ Btu/lbm}} = 3.22 \text{ lbm/s}$$

The mass of water stream at state 3 per unit mass of dry air is

$$m_3 = \frac{\dot{m}_3}{\dot{m}_a} = \frac{3 \text{ lbm water/s}}{3.22 \text{ lbm dry air/s}} = 0.9317 \text{ lbm water/lbm dry air}$$

The mass flow rate of water stream at state 4 per unit mass of dry air is

PROPRIETARY MATERIAL. © 2011 The McGraw-Hill Companies, Inc. Limited distribution permitted only to teachers and educators for course preparation. If you are a student using this Manual, you are using it without permission.

$$m_4 = m_3 - (\omega_2 - \omega_1) = 0.9317 - (0.0149 - 0.00391) = 0.9207 \text{ lbm water/lbm dry air}$$

The entropies of water streams are

$$s_3 = s_f @ 95^\circ\text{F} = 0.12065 \text{ Btu/lbm} \cdot \text{R}$$

$$s_4 = s_f @ 80^\circ\text{F} = 0.09328 \text{ Btu/lbm} \cdot \text{R}$$

The entropy change of water stream is

$$\Delta s_{\text{water}} = m_4 s_4 - m_3 s_3 = 0.9207 \times 0.09328 - 0.9317 \times 0.12065 = -0.02653 \text{ Btu/R} \cdot \text{lbgm dry air}$$

The entropies of water vapor in the air stream are

$$s_{g1} = s_g @ 65^\circ\text{F} = 2.0788 \text{ Btu/lbm} \cdot \text{R}$$

$$s_{g2} = s_g @ 80^\circ\text{F} = 2.0352 \text{ Btu/lbm} \cdot \text{R}$$

The entropy change of water vapor in the air stream is

$$\Delta s_{\text{vapor}} = \omega_2 s_{g2} - \omega_1 s_{g1} = 0.0149 \times 2.0352 - 0.00391 \times 2.0788 = 0.02220 \text{ Btu/R} \cdot \text{lbgm dry air}$$

The partial pressures of water vapor and dry air for air streams are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 65^\circ\text{F} = (0.30)(0.30578 \text{ psia}) = 0.0917 \text{ psia}$$

$$P_{a1} = P_1 - P_{v1} = 14.696 - 0.0917 = 14.60 \text{ psia}$$

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}} @ 75^\circ\text{F} = (0.80)(0.43016 \text{ psia}) = 0.3441 \text{ psia}$$

$$P_{a2} = P_2 - P_{v2} = 14.696 - 0.3441 = 14.35 \text{ psia}$$

The entropy change of dry air is

$$\begin{aligned} \Delta s_a &= s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} \\ &= (0.240) \ln \frac{535}{525} - (0.06855) \ln \frac{14.35}{14.60} = 0.005712 \text{ Btu/lbm dry air} \end{aligned}$$

The entropy generation in the cooling tower is the total entropy change:

$$s_{\text{gen}} = \Delta s_{\text{water}} + \Delta s_{\text{vapor}} + \Delta s_a = -0.02653 + 0.02220 + 0.005712 = 0.001382 \text{ Btu/R} \cdot \text{lbgm dry air}$$

Finally, the exergy destruction per unit mass of dry air is

$$x_{\text{dest}} = T_0 s_{\text{gen}} = (525 \text{ R})(0.001382 \text{ Btu/R} \cdot \text{lbgm dry air}) = \mathbf{0.726 \text{ Btu/lbm dry air}}$$

Review Problems

14-120 Air is compressed by a compressor and then cooled to the ambient temperature at high pressure. It is to be determined if there will be any condensation in the compressed air lines.

Assumptions The air and the water vapor are ideal gases.

Properties The saturation pressure of water at 20°C is 2.3392 kPa (Table A-4)..

Analysis The vapor pressure of air before compression is

$$P_{v1} = \phi_1 P_g = \phi_1 P_{\text{sat}} @ 25^\circ\text{C} = (0.50)(2.3392 \text{ kPa}) = 1.17 \text{ kPa}$$

The pressure ratio during the compression process is $(800 \text{ kPa})/(92 \text{ kPa}) = 8.70$. That is, the pressure of air and any of its components increases by 8.70 times. Then the vapor pressure of air after compression becomes

$$P_{v2} = P_{v1} \times (\text{Pressure ratio}) = (1.17 \text{ kPa})(8.70) = 10.2 \text{ kPa}$$

The dew-point temperature of the air at this vapor pressure is

$$T_{dp} = T_{\text{sat}} @ P_{v2} = T_{\text{sat}} @ 10.2 \text{ kPa} = 46.1^\circ\text{C}$$

which is greater than 20°C. Therefore, part of the moisture in the compressed air will **condense** when air is cooled to 20°C.

14-121E The mole fraction of the water vapor at the surface of a lake and the mole fraction of water in the lake are to be determined and compared.

Assumptions 1 Both the air and water vapor are ideal gases. **2** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 60°F is 0.2564 psia (Table A-4E). Henry's constant for air dissolved in water at 290 K (60°F) is given in Table 16-2 to be $H = 62,000 \text{ bar}$. Since we do not have the value at 50°F, we may use this value.

Analysis The air at the water surface will be saturated. Therefore, the partial pressure of water vapor in the air at the lake surface will simply be the saturation pressure of water at 60°F,

$$P_{\text{vapor}} = P_{\text{sat}} @ 60^\circ\text{F} = 0.1781 \text{ psia}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air at the surface of the lake is determined to be

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{0.1781 \text{ psia}}{14.5 \text{ psia}} = \mathbf{0.0123 \text{ (or 1.23 percent)}}$$

The partial pressure of dry air just above the lake surface is

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 14.5 - 0.1781 = 14.32 \text{ psia}$$

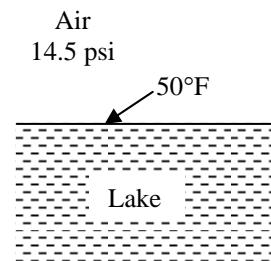

Then the mole fraction of air in the water becomes

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gasside}}}{H} = \frac{14.32 \text{ psia}(1 \text{ atm}/14.696 \text{ psia})}{62,000 \text{ bar}(1 \text{ atm}/1.01325 \text{ bar})} = 1.593 \times 10^{-5}$$

which is very small, as expected. Therefore, the mole fraction of water in the lake near the surface is

$$y_{\text{water, liquid side}} = 1 - y_{\text{dry air, liquid side}} = 1 - 1.593 \times 10^{-5} \approx \mathbf{1.0}$$

Discussion The concentration of air in water just below the air-water interface is 1.59 moles per 100,000 moles. The amount of air dissolved in water will decrease with increasing depth.

14-122E A room is cooled adequately by a 7500 Btu/h air-conditioning unit. If the room is to be cooled by an evaporative cooler, the amount of water that needs to be supplied to the cooler is to be determined.

Assumptions 1 The evaporative cooler removes heat at the same rate as the air conditioning unit. **2** Water evaporates at an average temperature of 70°F.

Properties The enthalpy of vaporization of water at 70°F is 1053.7 Btu/lbm (Table A-4E).

Analysis Noting that 1 lbm of water removes 1053.7 Btu of heat as it evaporates, the amount of water that needs to evaporate to remove heat at a rate of 7500 Btu/h is determined from $\dot{Q} = \dot{m}_{\text{water}} h_{fg}$ to be

$$\dot{m}_{\text{water}} = \frac{\dot{Q}}{h_{fg}} = \frac{7500 \text{ Btu/h}}{1053.7 \text{ Btu/lbm}} = 7.12 \text{ lbm/h}$$

14-123E The required size of an evaporative cooler in cfm (ft³/min) for an 8-ft high house is determined by multiplying the floor area of the house by 4. An equivalent rule is to be obtained in SI units.

Analysis Noting that 1 ft = 0.3048 m and thus 1 ft² = 0.0929 m² and 1 ft³ = 0.0283 m³, and noting that a flow rate of 4 ft³/min is required per ft² of floor area, the required flow rate in SI units per m² of floor area is determined to

$$\begin{aligned} 1 \text{ ft}^2 &\leftrightarrow 4 \text{ ft}^3 / \text{min} \\ 0.0929 \text{ m}^2 &\leftrightarrow 4 \times 0.0283 \text{ m}^3 / \text{min} \\ 1 \text{ m}^2 &\leftrightarrow 1.22 \text{ m}^3 / \text{min} \end{aligned}$$

Therefore, a flow rate of **1.22 m³/min** is required per m² of floor area.

14-124 A cooling tower with a cooling capacity of 220 kW is claimed to evaporate 9500 kg of water per day. It is to be determined if this is a reasonable claim.

Assumptions 1 Water evaporates at an average temperature of 30°C. **2** The coefficient of performance of the air-conditioning unit is COP = 3.

Properties The enthalpy of vaporization of water at 30°C is 2429.8 kJ/kg (Table A-4).

Analysis Using the definition of COP, the electric power consumed by the air conditioning unit when running is

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_{\text{cooling}}}{\text{COP}} = \frac{220 \text{ kW}}{3} = 73.33 \text{ kW}$$

Then the rate of heat rejected at the cooling tower becomes

$$\dot{Q}_{\text{rejected}} = \dot{Q}_{\text{cooling}} + \dot{W}_{\text{in}} = 220 + 73.33 = 293.3 \text{ kW}$$

Noting that 1 kg of water removes 2429.8 kJ of heat as it evaporates, the amount of water that needs to evaporate to remove heat at a rate of 293.3 kW is determined from $\dot{Q}_{\text{rejected}} = \dot{m}_{\text{water}} h_{fg}$ to be

$$\dot{m}_{\text{water}} = \frac{\dot{Q}_{\text{rejected}}}{h_{fg}} = \frac{293.3 \text{ kJ/s}}{2429.8 \text{ kJ/kg}} = 0.1207 \text{ kg/s} = 434.6 \text{ kg/h} = 10,430 \text{ kg/day}$$

In practice, the air-conditioner will run intermittently rather than continuously at the rated power, and thus the water use will be less. Therefore, the claim amount of 9500 kg per day is **reasonable**.

14-125E It is estimated that 190,000 barrels of oil would be saved per day if the thermostat setting in residences in summer were raised by 6°F (3.3°C). The amount of money that would be saved per year is to be determined.

Assumptions The average cooling season is given to be 120 days, and the cost of oil to be \$20/barrel.

Analysis The amount of money that would be saved per year is determined directly from

$$(190,000 \text{ barrel/day})(120 \text{ days/year})(\$20/\text{barrel}) = \$1,596,000,000$$

Therefore, the proposed measure will save more than one and half billion dollars a year.

14-126 Shading the condenser can reduce the air-conditioning costs by up to 10 percent. The amount of money shading can save a homeowner per year during its lifetime is to be determined.

Assumptions It is given that the annual air-conditioning cost is \$500 a year, and the life of the air-conditioning system is 20 years.

Analysis The amount of money that would be saved per year is determined directly from

$$(\$500/\text{year})(20 \text{ years})(0.10) = \$1000$$

Therefore, the proposed measure will save about \$1000 during the lifetime of the system.

14-127 Air at a specified state is heated to a specified temperature. The relative humidity after the heating is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The properties of the air at the ambient state are determined from the psychrometric chart (Figure A-31) to be

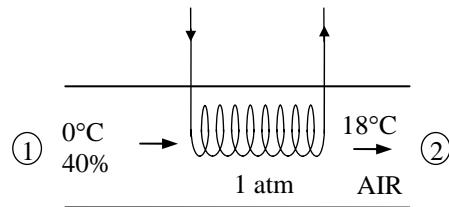

$$\omega_1 = 0.0015 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

As the outside air infiltrates into the dacha, it does not gain or lose any water. Therefore the humidity ratio inside the dacha is the same as that outside,

$$\omega_2 = \omega_1 = 0.0015 \text{ kg H}_2\text{O/kg dry air}$$

Entering the psychrometry chart at this humidity ratio and the temperature inside the dacha gives

$$\phi_2 = 0.118 = 11.8\%$$

14-128 Air is humidified by evaporating water into this air. The amount of heating per m³ of air is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 21.9 \text{ kJ/kg dry air}$$

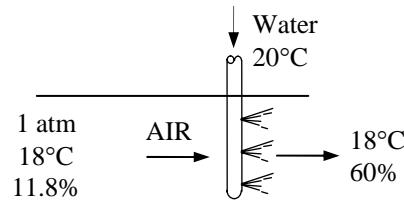

$$\omega_1 = 0.00151 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.8268 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 37.7 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00773 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \equiv h_f @ 20^\circ\text{C} = 83.92 \text{ kJ/kg} \quad (\text{Table A-4})$$

Analysis The amount of moisture in the air increases due to humidification ($\omega_2 > \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system}^{(0 \text{ (steady)})} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i + \dot{Q}_{in} = \sum \dot{m}_e h_e$$

$$\dot{Q}_{in} = \dot{m}_{a2} h_2 - \dot{m}_{a1} h_1 - \dot{m}_w h_w = \dot{m}_a (h_2 - h_1) - \dot{m}_w h_w$$

$$q_{in} = h_2 - h_1 - (\omega_2 - \omega_1) h_w$$

$$= (37.7 - 21.9) \text{ kJ/kg} - (0.00773 - 0.00151)(83.92)$$

$$= 15.28 \text{ kJ/kg dry air}$$

The heat transfer per unit volume is

$$Q_{in} = \frac{q_{in}}{v_1} = \frac{15.28 \text{ kJ/kg dry air}}{0.8268 \text{ m}^3/\text{kg dry air}} = \mathbf{18.5 \text{ kJ/m}^3}$$

14-129E Air is cooled by evaporating water into this air. The amount of water required and the cooling produced are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 35.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0082 \text{ lbm H}_2\text{O/lbm dry air}$$

and

$$h_2 = 34.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0149 \text{ lbm H}_2\text{O/lbm dry air}$$

Also,

$$h_w \equiv h_f @ 70^\circ\text{F} = 38.08 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

Analysis The amount of moisture in the air increases due to humidification ($\omega_2 > \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\Delta\omega = \omega_2 - \omega_1 = 0.0149 - 0.0082 = \mathbf{0.0067 \text{ lbm H}_2\text{O/klbm dry air}}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\text{sh0(steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

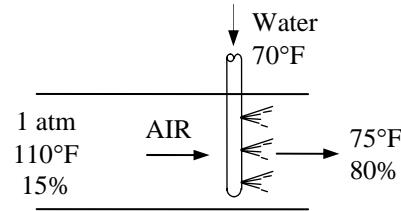

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 + \dot{m}_w h_w - \dot{m}_{a2}h_2 = \dot{m}_a(h_1 - h_2) + \dot{m}_w h_w$$

$$q_{\text{out}} = h_1 - h_2 + (\omega_2 - \omega_1)h_w$$

$$= (35.6 - 34.3)\text{Btu/lbm} + (0.0067)(38.08)$$

$$= \mathbf{1.47 \text{ Btu/lbm dry air}}$$

14-130E Air is humidified adiabatically by evaporating water into this air. The temperature of the air at the exit is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 35.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0082 \text{ lbm H}_2\text{O/lbm dry air}$$

and $h_w \equiv h_f @ 70^\circ\text{F} = 38.08 \text{ Btu/lbm}$ (Table A-4E)

Analysis The amount of moisture in the air increases due to humidification ($\omega_2 > \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

Water Mass Balance:

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w \\ \dot{m}_w &= \dot{m}_a(\omega_2 - \omega_1)\end{aligned}$$

Energy Balance:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{d0 (steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_{a1} h_1 + \dot{m}_w h_w &= \dot{m}_{a2} h_2 \\ \dot{m}_w h_w &= \dot{m}_a (h_2 - h_1) \\ (\omega_2 - \omega_1) h_w &= h_2 - h_1\end{aligned}$$

Substituting,

$$(\omega_2 - 0.0092)(83.92) = h_2 - 64.0$$

The solution of this equation requires a trial-error method. An air exit temperature is assumed. At this temperature and the given relative humidity, the enthalpy and specific humidity values are obtained from psychrometric chart and substituted into this equation. If the equation is not satisfied, a new value of exit temperature is assumed and this continues until the equation is satisfied. Alternatively, an equation solver such as EES may be used for the direct results. We used the following EES program to get these results:

$$T_2 = 79.6^\circ\text{F}$$

$$h_2 = 35.8 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0152 \text{ lbm H}_2\text{O/lbm dry air}$$

"Given"

$$P=14.696 \text{ [psia]}$$

$$T_1=110 \text{ [F]}$$

$$\phi_1=0.15$$

$$\phi_2=0.70$$

$$T_w=70 \text{ [F]}$$

"Analysis"

Fluid1\$='AirH2O'

Fluid2\$='steam_iapws'

$h_1=\text{enthalpy}(\text{Fluid1\$}, T=T_1, R=\phi_1, P=P)$

$w_1=\text{humrat}(\text{Fluid1\$}, T=T_1, R=\phi_1, P=P)$

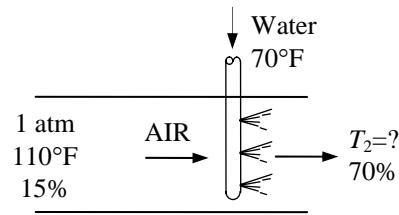

$h_2=\text{enthalpy}(\text{Fluid1\$}, T=T_2, R=\phi_2, P=P)$

$q=h_1-h_2+(w_2-w_1)*h_w$

14-131E Air is cooled and dehumidified at constant pressure. The rate of cooling and the minimum humid air temperature required to meet this cooling requirement are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 50.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0263 \text{ lbm H}_2\text{O/lbm dry air}$$

$$v_1 = 14.44 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 28.2 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit. Then,

$$h_w \approx h_f @ 82.5^\circ\text{F} = 50.56 \text{ Btu/lbm} \quad (\text{Table A-4})$$

Analysis The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The mass of air is

$$m_a = \frac{V_1}{v_1} = \frac{1000 \text{ ft}^3}{14.44 \text{ ft}^3 / \text{lbm dry air}} = 69.25 \text{ lbm}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$m_w = m_a(\omega_1 - \omega_2) = (69.25 \text{ kg})(0.0263 - 0.0093) = 1.177 \text{ lbm}$$

Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \xrightarrow{\text{0(steady)}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = m_a(h_1 - h_2) - m_w h_w$$

$$\begin{aligned} \dot{Q}_{out} &= (69.25 \text{ kg})(50.6 - 28.2) \text{ Btu/lbm} - (1.177 \text{ lbm})(50.56 \text{ Btu/lbm}) \\ &= \mathbf{1492 \text{ Btu}} \end{aligned}$$

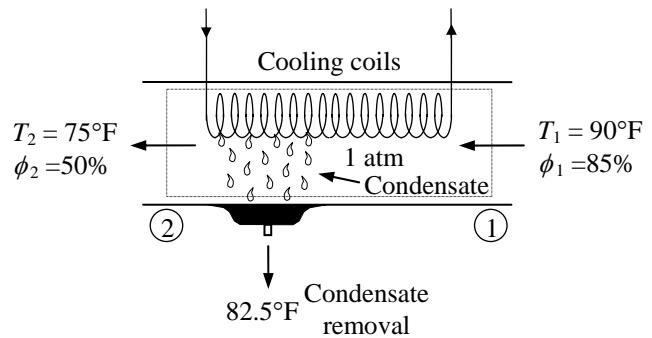

For the desired dehumidification, the air at the exit should be saturated with a specific humidity of 0.0093 lbm water/lbm dry air. That is,

$$\phi_2 = 1.0$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

The temperature of the air at this state is the minimum air temperature required during this process:

$$T_2 = \mathbf{55.2^\circ\text{F}}$$

14-132E Air is cooled and dehumidified at constant pressure by a simple ideal vapor-compression refrigeration system. The system's COP is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 50.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0263 \text{ lbm H}_2\text{O/lbm dry air}$$

$$v_1 = 14.44 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 28.2 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

For the desired dehumidification, the air at the exit should be saturated with a specific humidity of 0.0093 lbm water/lbm dry air. That is,

$$\phi_2 = 1.0$$

$$\omega_2 = 0.0093 \text{ lbm H}_2\text{O/lbm dry air}$$

The temperature of the air at this state is the minimum air temperature required during this process:

$$T_{2,\min} = 55.2^\circ\text{F}$$

From the problem statement, the properties of R-134a at various states are (Tables A-11E through A-13E or from EES):

$$\left. \begin{array}{l} T_1 = 55.2 - 10 = 45.2^\circ\text{F} \\ P_1 = P_{\text{sat}} @ 45.2^\circ\text{F} = 55 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \left. \begin{array}{l} h_1 = h_g @ 55 \text{ psia} = 109.49 \text{ Btu/lbm} \\ s_1 = s_g @ 55 \text{ psia} = 0.22156 \text{ Btu/lbm} \cdot \text{R} \end{array} \right.$$

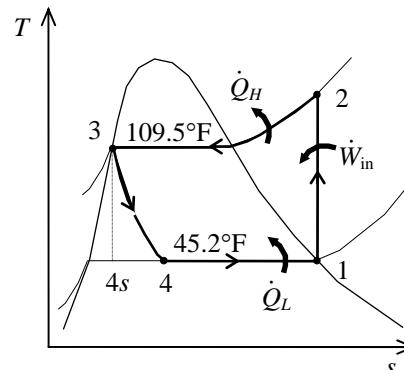

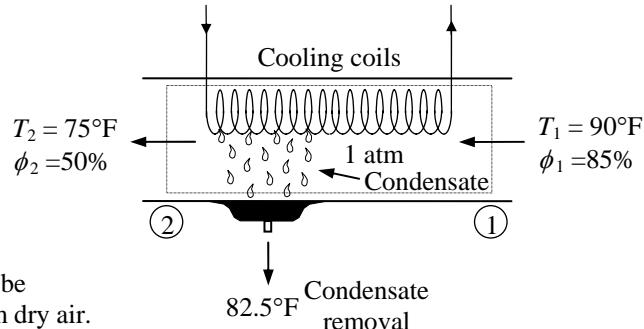

$$\left. \begin{array}{l} T_{\text{sat}} = 90 + 19.5 = 109.5^\circ\text{F} \\ P_2 = P_{\text{sat}} @ 109.5^\circ\text{F} = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} \left. \begin{array}{l} h_2 = 119.01 \text{ kJ/kg} \end{array} \right.$$

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} \left. \begin{array}{l} h_3 = h_f @ 160 \text{ psia} = 48.52 \text{ Btu/lbm} \end{array} \right.$$

$$h_4 \cong h_3 = 48.52 \text{ Btu/lbm} \quad (\text{throttling})$$

The COP of this system is then

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{109.49 - 48.52}{119.01 - 109.49} = \mathbf{6.40}$$

14-133 A tank contains saturated air at a specified state. The mass of the dry air, the specific humidity, and the enthalpy of the air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The air is saturated, thus the partial pressure of water vapor is equal to the saturation pressure at the given temperature,

$$P_v = P_g = P_{\text{sat} @ 20^\circ\text{C}} = 2.339 \text{ kPa}$$

$$P_a = P - P_v = 90 - 2.339 = 87.66 \text{ kPa}$$

Treating air as an ideal gas,

$$m_a = \frac{P_a V}{R_a T} = \frac{(87.66 \text{ kPa})(1.8 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})} = \mathbf{1.88 \text{ kg}}$$

1.8 m ³
20°C
90 kPa

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(2.339 \text{ kPa})}{(90 - 2.339) \text{ kPa}} = \mathbf{0.0166 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \approx c_p T + \omega h_g \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0166)(2537.4 \text{ kJ/kg}) \\ &= \mathbf{62.2 \text{ kJ/kg dry air}} \end{aligned}$$

14-134 Problem 14-133 is reconsidered. The properties of the air at the initial state are to be determined and the effects of heating the air at constant volume until the pressure is 110 kPa is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data:"

$$\begin{aligned} T_{db[1]} &= 20 \text{ [C]} \\ P[1] &= 90 \text{ [kPa]} \\ R_h[1] &= 1.0 \\ P[2] &= 110 \text{ [kPa]} \\ \text{Vol} &= 1.8 \text{ [m}^3\text{]} \end{aligned}$$

$$w[1]=\text{HUMRAT}(\text{AirH2O}, T=T_{db[1]}, P=P[1], R=R_h[1])$$

$$v[1]=\text{VOLUME}(\text{AirH2O}, T=T_{db[1]}, P=P[1], R=R_h[1])$$

$$m_a=\text{Vol}/v[1]$$

$$h[1]=\text{ENTHALPY}(\text{AirH2O}, T=T_{db[1]}, P=P[1], w=w[1])$$

"Energy Balance for the constant volume tank:"

$$E_{in} - E_{out} = \text{DELTAE_tank}$$

$$\text{DELTAE_tank}=m_a*(u[2] - u[1])$$

$$E_{in} = Q_{in}$$

$$E_{out} = 0 \text{ [kJ]}$$

$$u[1]=\text{INTENERGY}(\text{AirH2O}, T=T_{db[1]}, P=P[1], w=w[1])$$

$$u[2]=\text{INTENERGY}(\text{AirH2O}, T=T_{db[2]}, P=P[2], w=w[2])$$

"The ideal gas mixture assumption applied to the constant volume process yields:"

$$P[1]/(T_{db[1]}+273)=P[2]/(T_{db[2]}+273)$$

"The mass of the water vapor and dry air are constant, thus:"

$$w[2]=w[1]$$

$$R_h[2]=\text{RELHUM}(\text{AirH2O}, T=T_{db[2]}, P=P[2], w=w[2])$$

$$h[2]=\text{ENTHALPY}(\text{AirH2O}, T=T_{db[2]}, P=P[2], w=w[2])$$

$$v[2]=\text{VOLUME}(\text{AirH2O}, T=T_{db[2]}, P=P[2], R=R_h[2])$$

PROPERTIES AT THE INITIAL STATE

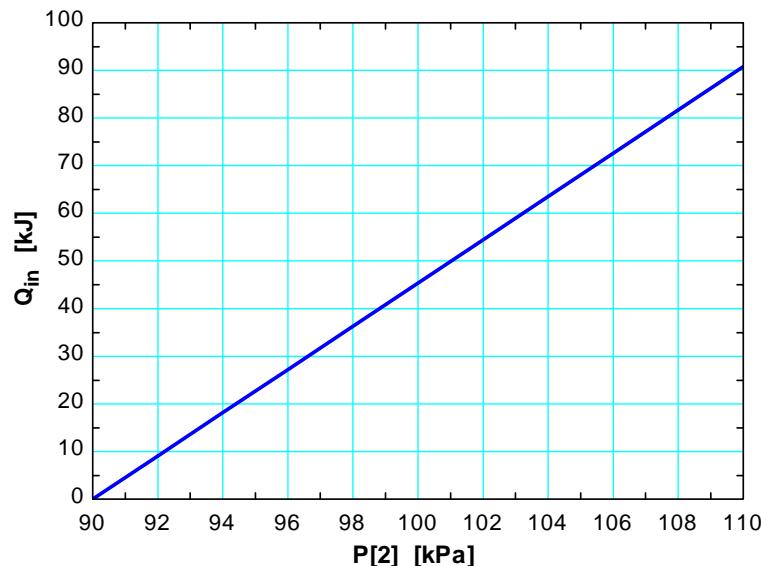

$$h[1]=62.25 \text{ [kJ/kg a]}$$

$$m_a=1.875 \text{ [kg a]}$$

$$v[1]=0.9599 \text{ [m}^3/\text{kg a}\text{]}$$

$$w[1]=0.01659 \text{ [kg w/kg a]}$$

P ₂ [kPa]	Q _{in} [kJ]
90	0
92	9.071
94	18.14
96	27.22
98	36.29
100	45.37
102	54.44
104	63.52
106	72.61
108	81.69
110	90.78

14-135E Air at a specified state and relative humidity flows through a circular duct. The dew-point temperature, the volume flow rate of air, and the mass flow rate of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The vapor pressure of air is

$$P_v = \phi P_g = \phi P_{\text{sat}} @ 60^{\circ}\text{F} = (0.50)(0.2564 \text{ psia}) = 0.128 \text{ psia}$$

Thus the dew-point temperature of the air is

$$T_{dp} = T_{\text{sat}} @ P_v = T_{\text{sat}} @ 0.128 \text{ psia} = 41.3^{\circ}\text{F} \text{ (from EES)}$$

(b) The volume flow rate is determined from

$$\dot{V} = VA = V \frac{\pi D^2}{4} = (50 \text{ ft/s}) \left(\frac{\pi \times (8/12 \text{ ft})^2}{4} \right) = 17.45 \text{ ft}^3/\text{s}$$

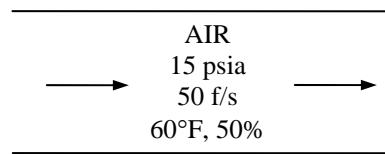

(c) To determine the mass flow rate of dry air, we first need to calculate its specific volume,

$$P_a = P - P_v = 15 - 0.128 = 14.872 \text{ psia}$$

$$v_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(520 \text{ R})}{14.872 \text{ psia}} = 12.95 \text{ ft}^3 / \text{lbm dry air}$$

Thus,

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{17.45 \text{ ft}^3 / \text{s}}{12.95 \text{ ft}^3 / \text{lbm dry air}} = 1.35 \text{ lbm/s}$$

14-136 Air enters a cooling section at a specified pressure, temperature, and relative humidity. The temperature of the air at the exit and the rate of heat transfer are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air also remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The total pressure is 97 kPa. The properties of the air at the inlet state are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 35^\circ\text{C} = (0.3)(5.629 \text{ kPa}) = 1.69 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 97 - 1.69 = 95.31 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(308 \text{ K})}{95.31 \text{ kPa}} \\ = 0.927 \text{ m}^3/\text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.69 \text{ kPa})}{(97 - 1.69) \text{ kPa}} = 0.0110 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg}\cdot^\circ\text{C})(35^\circ\text{C}) + (0.0110)(2564.6 \text{ kJ/kg}) = 63.44 \text{ kJ/kg dry air}$$

The air at the final state is saturated and the vapor pressure during this process remains constant. Therefore, the exit temperature of the air must be the dew-point temperature,

$$T_{dp} = T_{\text{sat}} @ P_v = T_{\text{sat}} @ 1.69 \text{ kPa} = \mathbf{14.8^\circ\text{C}}$$

(b) The enthalpy of the air at the exit is

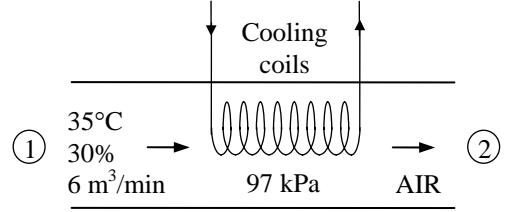

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg}\cdot^\circ\text{C})(14.8^\circ\text{C}) + (0.0110)(2528.1 \text{ kJ/kg}) = 42.78 \text{ kJ/kg dry air}$$

Also

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{6 \text{ m}^3/\text{s}}{0.927 \text{ m}^3/\text{kg dry air}} = 6.47 \text{ kg/min}$$

Then the rate of heat transfer from the air in the cooling section becomes

$$\dot{Q}_{\text{out}} = \dot{m}_a (h_1 - h_2) = (6.47 \text{ kg/min})(63.44 - 42.78) \text{ kJ/kg} = \mathbf{134 \text{ kJ/min}}$$

14-137 The outdoor air is first heated and then humidified by hot steam in an air-conditioning system. The rate of heat supply in the heating section and the mass flow rate of the steam required in the humidifying section are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The amount of moisture in the air also remains constant as it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 17.7 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0030 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

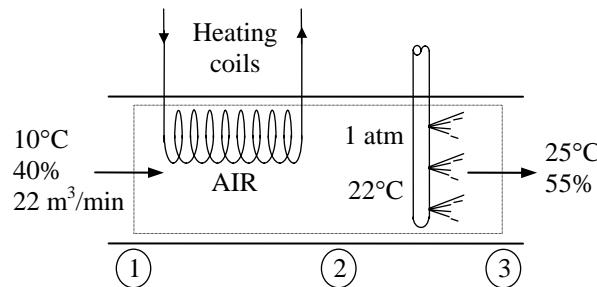

$$v_1 = 0.807 \text{ m}^3/\text{kg dry air}$$

$$h_2 = 29.8 \text{ kJ / kg dry air}$$

$$\omega_2 = \omega_1 = 0.0030 \text{ kg H}_2\text{O / kg dry air}$$

$$h_3 = 52.9 \text{ kJ / kg dry air}$$

$$\omega_3 = 0.0109 \text{ kg H}_2\text{O / kg dry air}$$

Analysis (a) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{22 \text{ m}^3 / \text{min}}{0.807 \text{ m}^3 / \text{kg}} = 27.3 \text{ kg/min}$$

Then the rate of heat transfer to the air in the heating section becomes

$$\dot{Q}_{in} = \dot{m}_a(h_2 - h_1) = (27.3 \text{ kg / min})(29.8 - 17.7) \text{ kJ / kg} = \mathbf{330.3 \text{ kJ / min}}$$

(b) The conservation of mass equation for water in the humidifying section can be expressed as

$$\dot{m}_{a2}\omega_2 + \dot{m}_w = \dot{m}_{a3}\omega_3 \quad \text{or} \quad \dot{m}_w = \dot{m}_a(\omega_3 - \omega_2)$$

Thus,

$$\dot{m}_w = (27.3 \text{ kg / min})(0.0109 - 0.0030) = \mathbf{0.216 \text{ kg / min}}$$

14-138 Air is cooled and dehumidified in an air-conditioning system with refrigerant-134a as the working fluid. The rate of dehumidification, the rate of heat transfer, and the mass flow rate of the refrigerant are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The saturation pressure of water at 30°C is 4.2469 kPa. Then the dew point temperature of the incoming air stream at 30°C becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.7 \times 4.2469 \text{ kPa}} = 24^\circ\text{C}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The mass flow rate of dry air remains constant during the entire process, but the amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 78.3 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0188 \text{ kg H}_2\text{O/kg dry air}$$

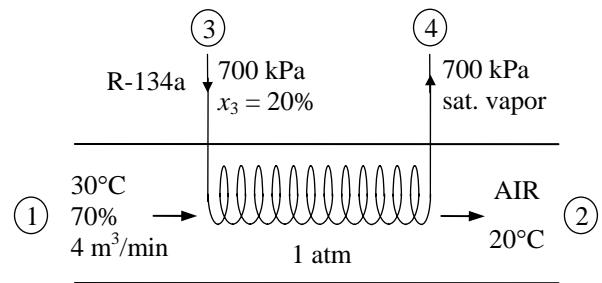

$$v_1 = 0.885 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 57.5 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O/kg dry air}$$

Also, $h_w \approx h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg}$ (Table A-4)

$$\text{Then, } \dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{4 \text{ m}^3/\text{min}}{0.885 \text{ m}^3/\text{kg dry air}} = 4.52 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the refrigerant),

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (4.52 \text{ kg/min})(0.0188 - 0.0147) = \mathbf{0.0185 \text{ kg/min}}$$

(b) **Energy Balance:**

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system}^{(0 \text{ steady})} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e \longrightarrow \dot{Q}_{out} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (4.52 \text{ kg/min})(78.3 - 57.5) \text{ kJ/kg} - (0.0185 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{92.5 \text{ kJ/min}}$$

(c) The inlet and exit enthalpies of the refrigerant are

$$h_3 = h_g + x_3 h_{fg} = 88.82 + 0.2 \times 176.21 = 124.06 \text{ kJ/kg}$$

$$h_4 = h_g @ 700 \text{ kPa} = 265.03 \text{ kJ/kg}$$

Noting that the heat lost by the air is gained by the refrigerant, the mass flow rate of the refrigerant becomes

$$\dot{Q}_R = \dot{m}_R (h_4 - h_3) \rightarrow \dot{m}_R = \frac{\dot{Q}_R}{h_4 - h_3} = \frac{92.5 \text{ kJ/min}}{(265.03 - 124.06) \text{ kJ/kg}} = \mathbf{0.66 \text{ kg/min}}$$

14-139 Air is cooled and dehumidified in an air-conditioning system with refrigerant-134a as the working fluid. The rate of dehumidification, the rate of heat transfer, and the mass flow rate of the refrigerant are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Analysis (a) The dew point temperature of the incoming air stream at 30°C is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 30^\circ\text{C} = (0.7)(4.247 \text{ kPa}) = 2.973 \text{ kPa}$$

$$T_{dp} = T_{\text{sat}} @ P_{v1} = T_{\text{sat}} @ 2.973 \text{ kPa} = 24^\circ\text{C}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. The properties of the air at both states are determined to be

$$P_{a1} = P_1 - P_{v1} = 95 - 2.97 = 92.03 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(303 \text{ K})}{92.03 \text{ kPa}} = 0.945 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(2.97 \text{ kPa})}{(95 - 2.97) \text{ kPa}} = 0.0201 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.0201)(2555.6 \text{ kJ/kg}) = 81.50 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = (1.00)P_{\text{sat}} @ 20^\circ\text{C} = 2.3392 \text{ kPa}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(2.3392 \text{ kPa})}{(95 - 2.3392) \text{ kPa}} = 0.0157 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0157)(2537.4 \text{ kJ/kg}) = 59.94 \text{ kJ/kg dry air}$$

Also, $h_w \equiv h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg}$ (Table A-4)

$$\text{Then, } \dot{m}_{al} = \frac{\dot{V}}{\nu_1} = \frac{4 \text{ m}^3 / \text{min}}{0.945 \text{ m}^3 / \text{kg dry air}} = 4.23 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the refrigerant),

Water Mass Balance: $\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (4.23 \text{ kg/min})(0.0201 - 0.0157) = \mathbf{0.0186 \text{ kg/min}}$$

(b) *Energy Balance:*

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \xrightarrow{\text{no (steady)}} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e \longrightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (4.23 \text{ kg/min})(81.50 - 59.94) \text{ kJ/kg} - (0.0186 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{89.7 \text{ kJ/min}}$$

(c) The inlet and exit enthalpies of the refrigerant are

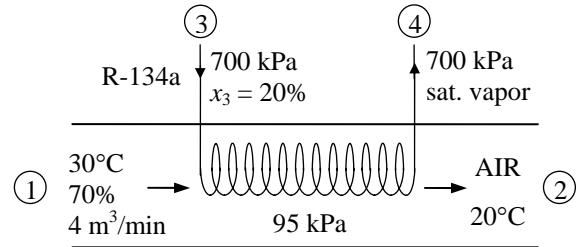

$$h_3 = h_g + x_3 h_{fg} = 88.82 + 0.2 \times 176.21 = 124.06 \text{ kJ/kg}$$

$$h_4 = h_g @ 700 \text{ kPa} = 265.03 \text{ kJ/kg}$$

Noting that the heat lost by the air is gained by the refrigerant, the mass flow rate of the refrigerant is determined from

$$\dot{Q}_R = \dot{m}_R (h_4 - h_3)$$

$$\dot{m}_R = \frac{\dot{Q}_R}{h_4 - h_3} = \frac{89.7 \text{ kJ/min}}{(265.03 - 124.06) \text{ kJ/kg}} = \mathbf{0.636 \text{ kg/min}}$$

14-140 Air is heated and dehumidified in an air-conditioning system consisting of a heating section and an evaporative cooler. The temperature and relative humidity of the air when it leaves the heating section, the rate of heat transfer in the heating section, and the rate of water added to the air in the evaporative cooler are to be determined.

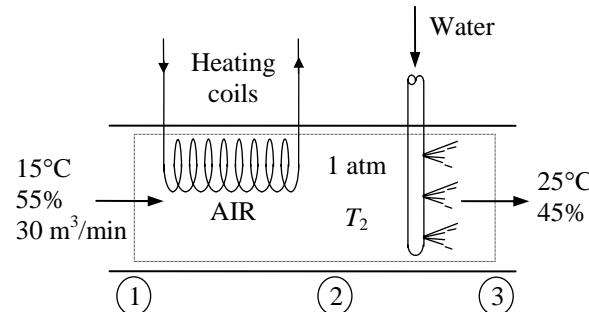

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) Assuming the wet-bulb temperature of the air remains constant during the evaporative cooling process, the properties of air at various states are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$\left. \begin{array}{l} T_1 = 15^\circ\text{C} \\ \omega_1 = 55\% \\ v_1 = 0.824 \text{ m}^3/\text{kg} \end{array} \right\} \begin{array}{l} h_1 = 29.8 \text{ kJ/kg dry air} \\ \omega_1 = 0.00581 \text{ kg/H}_2\text{O/kg dry air} \end{array}$$

$$\left. \begin{array}{l} \omega_2 = \omega_1 \\ T_{wb2} = T_{wb3} \end{array} \right\} \begin{array}{l} T_2 = 32.5^\circ\text{C} \\ \phi_2 = 19.2\% \\ h_2 \approx h_3 = 47.8 \text{ kJ/kg dry air} \end{array}$$

$$\left. \begin{array}{l} T_3 = 25^\circ\text{C} \\ \phi_3 = 45\% \end{array} \right\} \begin{array}{l} h_3 = 47.8 \text{ kJ/kg dry air} \\ \omega_3 = 0.00888 \text{ kg/H}_2\text{O/kg dry air} \\ T_{wb3} = 17.1^\circ\text{C} \end{array}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{v_1} = \frac{30 \text{ m}^3/\text{min}}{0.824 \text{ m}^3/\text{kg dry air}} = 36.4 \text{ kg/min}$$

Then the rate of heat transfer to air in the heating section becomes

$$\dot{Q}_{in} = \dot{m}_a(h_2 - h_1) = (36.4 \text{ kg/min})(47.8 - 29.8) \text{ kJ/kg} = \mathbf{655 \text{ kJ/min}}$$

(c) The rate of water added to the air in evaporative cooler is

$$\dot{m}_{w, \text{added}} = \dot{m}_{w3} - \dot{m}_{w2} = \dot{m}_a(\omega_3 - \omega_2) = (36.4 \text{ kg/min})(0.00888 - 0.00581) = \mathbf{0.112 \text{ kg/min}}$$

14-141 Problem 14-140 is reconsidered. The effect of total pressure in the range 94 to 100 kPa on the results required in the problem is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

```
P=101.325 [kPa]
Tdb[1] =15 [C]
Rh[1] = 0.55
Vol_dot[1]= 30 [m^3/min]
Tdb[3] = 25 [C]
Rh[3] = 0.45
P[1]=P
P[2]=P[1]
P[3]=P[1]
```

14-142 Air is heated and dehumidified in an air-conditioning system consisting of a heating section and an evaporative cooler. The temperature and relative humidity of the air when it leaves the heating section, the rate of heat transfer in the heating section, and the rate at which water is added to the air in the evaporative cooler are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Analysis (a) Assuming the wet-bulb temperature of the air remains constant during the evaporative cooling process, the properties of air at various states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 15^\circ\text{C}} = (0.55)(1.7057 \text{ kPa}) = 0.938 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 96 - 0.938 = 95.06 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(288 \text{ K})}{95.06 \text{ kPa}} = 0.8695 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.8695 \text{ kPa})}{(96 - 0.8695) \text{ kPa}} = 0.006138 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(15^\circ\text{C}) + (0.006138)(2528.3 \text{ kJ/kg}) = 30.59 \text{ kJ/kg dry air}$$

and

$$P_{v3} = \phi_3 P_{g3} = \phi_3 P_{\text{sat} @ 25^\circ\text{C}} = (0.45)(3.17 \text{ kPa}) = 1.426 \text{ kPa}$$

$$P_{a3} = P_3 - P_{v3} = 96 - 1.426 = 94.57 \text{ kPa}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}} = \frac{0.622(1.426 \text{ kPa})}{(96 - 1.426) \text{ kPa}} = 0.009381 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = c_p T_3 + \omega_3 h_{g3} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.009381)(2546.5 \text{ kJ/kg}) = 49.01 \text{ kJ/kg dry air}$$

Also,

$$h_2 \cong h_3 = 49.01 \text{ kJ/kg}$$

$$\omega_2 = \omega_1 = 0.006138 \text{ kg H}_2\text{O/kg dry air}$$

Thus,

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82T_2) = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})T_2 + (0.006138)(2500.9 + 1.82T_2)$$

Solving for T_2 ,

$$T_2 = 33.1^\circ\text{C} \longrightarrow P_{g2} = P_{\text{sat} @ 33.1^\circ\text{C}} = 5.072 \text{ kPa}$$

$$\text{Thus, } \phi_2 = \frac{\omega_2 P_2}{(0.622 + \omega_2) P_{g2}} = \frac{(0.006138)(96)}{(0.622 + 0.006138)(5.072)} = 0.185 \text{ or } 18.5\%$$

(b) The mass flow rate of dry air is

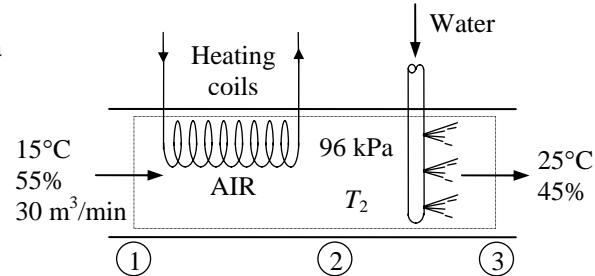

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{30 \text{ m}^3 / \text{min}}{0.8695 \text{ m}^3 / \text{kg dry air}} = 34.5 \text{ kg/min}$$

Then the rate of heat transfer to air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (34.5 \text{ kg/min})(49.01 - 30.59) \text{ kJ/kg} = 636 \text{ kJ/min}$$

(c) The rate of water addition to the air in evaporative cooler is

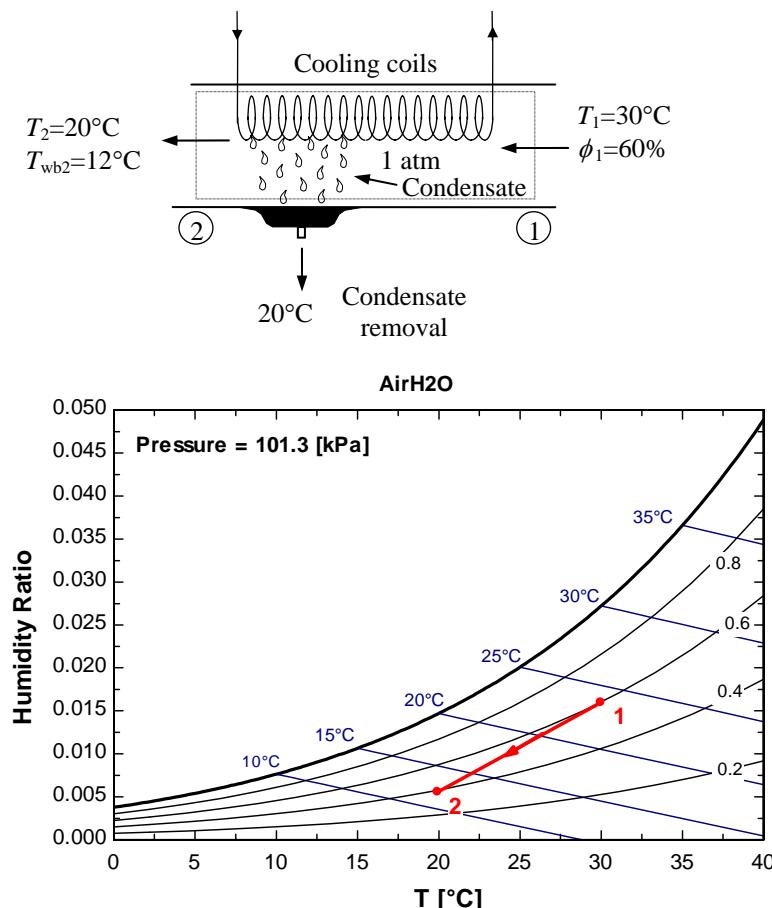

$$\dot{m}_{w,\text{added}} = \dot{m}_{w3} - \dot{m}_{w2} = \dot{m}_a (\omega_3 - \omega_2) = (34.5 \text{ kg/min})(0.009381 - 0.006138) = 0.112 \text{ kg/min}$$

14-143 Air is cooled, dehumidified and heated at constant pressure. The system hardware and the psychrometric diagram are to be sketched and the heat transfer is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The schematic of the cooling and dehumidification process and the the process on the psychrometric chart are given below. The psychrometric chart is obtained from the Property Plot feature of EES.

(b) The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states are determined from the psychrometric chart (Figure A-31 or EES) to be

$$h_1 = 71.2 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0160 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.881 \text{ m}^3/\text{kg dry air}$$

and

$$\phi_2 = 0.376$$

$$h_2 = 33.9 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00544 \text{ kg H}_2\text{O/kg dry air}$$

$$v_2 = 0.838 \text{ m}^3/\text{kg dry air}$$

Also,

$$h_w \cong h_f @ 20^\circ\text{C} = 83.9 \text{ kJ/kg} \quad (\text{Table A-4})$$

The mass flow rate of air in the room to be replaced is

$$\dot{m}_a = \frac{\dot{V}_2}{\nu_2} = \frac{(700 / 60 \text{ m}^3/\text{s})}{0.838 \text{ m}^3/\text{kg}} = 13.93 \text{ kg/s}$$

The mass flow rate of outside air is

$$\dot{m}_{out} = \dot{m}_{out} (1 + \omega_1) = (13.93 \text{ kg/s})(1 + 0.0160) = 14.15 \text{ kg/s} = \mathbf{50,940 \text{ kg/h}}$$

(c) Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2)$$

Substituting,

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = (13.93 \text{ kg/s})(0.0160 - 0.00544) = 0.147 \text{ kg/s} = \mathbf{8.83 \text{ kg/min}}$$

(d) *Energy Balance:*

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \xrightarrow{\text{for steady state}} 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \dot{Q}_{out} + \sum \dot{m}_e h_e \\ \dot{Q}_{out} &= \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) \\ &= \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w \end{aligned}$$

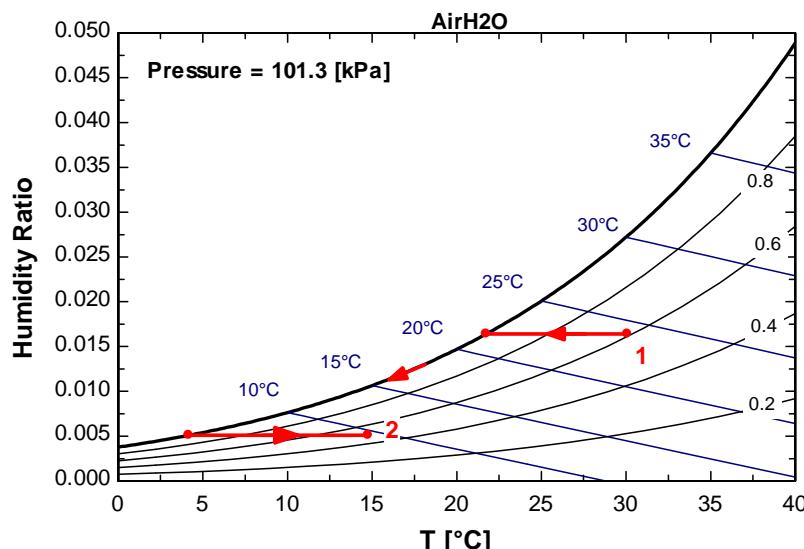

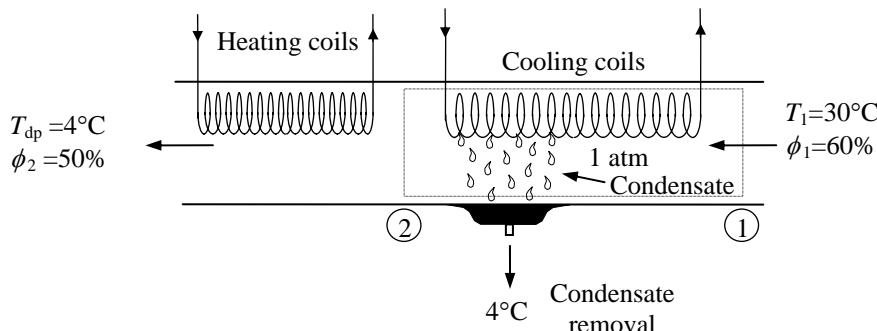

Noting that the cooling water absorbs this heat, the mass flow rate of cooling water is determined from

$$\begin{aligned} \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w &= \dot{m}_{cw} c_{pw} \Delta T_{cw} \\ \dot{m}_{cw} &= \frac{\dot{m}_a (h_1 - h_2) - \dot{m}_w h_w}{c_{pw} \Delta T_{cw}} \\ &= \frac{(13.93 \text{ kg/s})(71.2 - 33.9) \text{ kJ/kg} - (0.147 \text{ kg/s})(83.9 \text{ kJ/kg})}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(15^\circ\text{C})} \\ &= 8.08 \text{ kg/s} \\ &= \mathbf{485 \text{ kg/min}} \end{aligned}$$

14-144 Air is cooled, dehumidified and heated at constant pressure. The system hardware and the psychrometric diagram are to be sketched and the heat transfer is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The schematic of the cooling and dehumidification process and the the process on the psychrometric chart are given below. The psychrometric chart is obtained from the Property Plot feature of EES.

(b) The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states are determined from the psychrometric chart (Figure A-31 or EES) to be

$$T_{dp} = 21.4^\circ\text{C}$$

$$h_1 = 71.2 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0160 \text{ kg H}_2\text{O/kg dry air}$$

$$v_1 = 0.881 \text{ m}^3/\text{kg dry air}$$

and

$$T_2 = 14.3^\circ\text{C}$$

$$\phi_2 = 0.50$$

$$h_2 = 27.1 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00504 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \equiv h_f @ 4^\circ\text{C} = 16.8 \text{ kJ/kg} \quad (\text{Table A-4})$$

The volume flow rate at the inlet is

$$\dot{V}_1 = \dot{m}_a v_1 = (100/60 \text{ kg/s})(0.881 \text{ m}^3/\text{kg}) = \mathbf{1.47 \text{ m}^3/\text{s}}$$

(c) Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2)$$

Energy Balance:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \xrightarrow{\text{for } 0 \text{ (steady)}} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e \\ \dot{Q}_{\text{out}} &= \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) \\ &= \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w \\ &= \dot{m}_a(h_1 - h_2) - \dot{m}_a(\omega_1 - \omega_2)h_w \end{aligned}$$

Substituting,

$$\begin{aligned} \dot{Q}_{\text{out}} &= \dot{m}_a[(h_1 - h_2) - (\omega_1 - \omega_2)h_w] \\ &= (100/60 \text{ kg/s})(71.2 - 27.1) \text{ kJ/kg} - (0.0160 - 0.00504)(16.8 \text{ kJ/kg}) \\ &= \mathbf{73.2 \text{ kW}} \end{aligned}$$

14-145 Waste heat from the cooling water is rejected to air in a natural-draft cooling tower. The mass flow rate of the cooling water, the volume flow rate of air, and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation is made up later in the cycle using water at 30°C. Applying the mass balance and the energy balance equations yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned}\sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \\ \dot{m}_3 + \dot{m}_{a1}\omega_1 &= \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}\end{aligned}$$

Energy Balance:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\text{0(steady)}} = 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3\end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31 or EES),

$$h_1 = 44.67 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.008462 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8504 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 110.69 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.03065 \text{ kg H}_2\text{O/kg dry air}$$

From Table A-4,

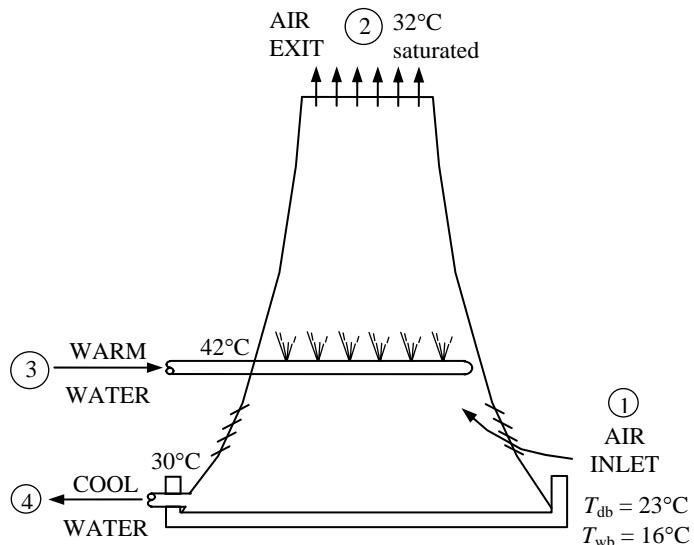

$$h_3 \cong h_f @ 42^\circ\text{C} = 175.90 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O}$$

Substituting

$$\dot{m}_a = \frac{\dot{m}_3(175.90 - 125.74) \text{ kJ/kg}}{(110.69 - 44.67) \text{ kJ/kg} - (0.03065 - 0.008462)(125.74) \text{ kJ/kg}} = 0.7933\dot{m}_3$$

The mass flow rate of the cooling water is determined by applying the steady flow energy balance equation on the cooling water,

$$\begin{aligned}
 \dot{Q}_{\text{waste}} &= \dot{m}_3 h_3 - (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 = \dot{m}_3 h_3 - [\dot{m}_3 - \dot{m}_a (\omega_2 - \omega_1)] h_4 \\
 &= \dot{m}_3 h_3 - \dot{m}_3 [1 - 0.7933(0.03065 - 0.008462)] h_4 \\
 &= \dot{m}_3 (h_3 - 0.9824 h_4)
 \end{aligned}$$

$$70,000 \text{ kJ/s} = \dot{m}_3 (175.90 - 0.9824 \times 125.74) \text{ kJ/kg} \longrightarrow \dot{m}_3 = \mathbf{1337 \text{ kg/s}}$$

and

$$\dot{m}_a = 0.7933 \dot{m}_3 = (0.7933)(1337 \text{ kg/s}) = 1061 \text{ kg/s}$$

(b) Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a v_1 = (1061 \text{ kg/s})(0.8504 \text{ m}^3 / \text{kg}) = \mathbf{902 \text{ m}^3/s}$$

(c) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a (\omega_2 - \omega_1) = (1061 \text{ kg/s})(0.03065 - 0.008462) = \mathbf{23.5 \text{ kg/s}}$$

14-146 Problem 14-145 is reconsidered. The effect of air inlet wet-bulb temperature on the required air volume flow rate and the makeup water flow rate is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data"

```
P_atm =101.325 [kPa]

23	1424	21.3	1342	1651

14-147 An uninsulated tank contains moist air at a specified state. Water is sprayed into the tank until the relative humidity in the tank reaches a certain value. The amount of water supplied to the tank, the final pressure in the tank, and the heat transfer during the process are to be determined.

Assumptions 1 Dry air and water vapor are ideal gases. 2 The kinetic and potential energy changes are negligible.

Analysis The initial state of the moist air is completely specified. The properties of the air at the inlet state may be determined from the psychrometric chart (Figure A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 49.16 \text{ kJ/kg dry air}, \quad \omega_1 = 0.005433 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.6863 \text{ m}^3 / \text{kg dry air}$$

The initial mass in the tank is

$$m_a = \frac{\nu_1}{\nu} = \frac{0.5 \text{ m}^3}{0.6863 \text{ m}^3} = 0.7285 \text{ kg}$$

The partial pressure of dry air in the tank is

$$P_{a2} = \frac{m_a R_a T_2}{\nu} = \frac{(0.7285 \text{ kg})(0.287 \text{ kJ/kg.K})(35 + 273 \text{ K})}{(0.5 \text{ m}^3)} = 128.8 \text{ kPa}$$

Then, the pressure of moist air in the tank is determined from

$$P_2 = P_{a2} \left(1 + \frac{\omega_2}{0.622} \right) = (128.8 \text{ kPa}) \left(1 + \frac{\omega_2}{0.622} \right)$$

We cannot fix the final state explicitly by a hand-solution. However, using EES which has built-in functions for moist air properties, the final state properties are determined to be

$$P_2 = 133.87 \text{ kPa} \quad \omega_2 = 0.02446 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = 97.97 \text{ kJ/kg dry air} \quad \nu_2 = 0.6867 \text{ m}^3 / \text{kg dry air}$$

The partial pressures at the initial and final states are

$$P_{v1} = \phi_1 P_{\text{sat}@35^\circ\text{C}} = 0.20(5.6291 \text{ kPa}) = 1.126 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 130 - 1.126 = 128.87 \text{ kPa}$$

$$P_{v2} = P_2 - P_{a2} = 133.87 - 128.81 = 5.07 \text{ kPa}$$

The specific volume of water at 35°C is

$$\nu_{w1} = \nu_{w2} = \nu_g @ 35^\circ\text{C} = 25.205 \text{ m}^3/\text{kg}$$

The internal energies per unit mass of dry air in the tank are

$$u_1 = h_1 - P_{a1}\nu_1 - w_1 P_{v1}\nu_{w1} = 49.16 - 128.87 \times 0.6863 - 0.005433 \times 1.126 \times 25.205 = -39.44 \text{ kJ/kg}$$

$$u_2 = h_2 - P_{a2}\nu_2 - w_2 P_{v2}\nu_{w2} = 97.97 - 128.81 \times 0.6867 - 0.02446 \times 5.07 \times 25.205 = 6.396 \text{ kJ/kg}$$

The enthalpy of water entering the tank from the supply line is

$$h_{wl} = h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg}$$

The internal energy of water vapor at the final state is

$$u_{w2} = u_g @ 35^\circ\text{C} = 2422.7 \text{ kJ/kg}$$

The amount of water supplied to the tank is

$$m_w = m_a (\omega_2 - \omega_1) = (0.7285 \text{ kg})(0.02446 - 0.005433) = \mathbf{0.01386 \text{ kg}}$$

An energy balance on the system gives

$$E_{\text{in}} = \Delta E_{\text{tank}}$$

$$Q_{\text{in}} + m_w h_{wl} = m_a (u_2 - u_1) + m_w u_{w2}$$

$$Q_{\text{in}} + (0.01386 \text{ kg})(209.34 \text{ kJ/kg}) = (0.7285 \text{ kg})[6.396 - (-39.44) \text{ kJ/kg}] + (0.01386 \text{ kg})(2422.7 \text{ kJ/kg})$$

$$\dot{Q}_{\text{in}} = \mathbf{64.1 \text{ kJ}}$$

Fundamentals of Engineering (FE) Exam Problems

14-148 A room is filled with saturated moist air at 25°C and a total pressure of 100 kPa. If the mass of dry air in the room is 100 kg, the mass of water vapor is

- (a) 0.52 kg (b) 1.97 kg (c) 2.96 kg (d) 2.04 kg (e) 3.17 kg

Answer (d) 2.04 kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=25 "C"
P=100 "kPa"
m_air=100 "kg"
RH=1
P_g=PRESSURE(Steam_IAPWS,T=T1,x=0)
RH=P_v/P_g
P_air=P-P_v
w=0.622*P_v/(P-P_v)
w=m_v/m_air
```

"Some Wrong Solutions with Common Mistakes:"

W1_vmass=m_air*w1; w1=0.622*P_v/P "Using P instead of P-Pv in w relation"

W2_vmass=m_air "Taking m_vapor = m_air"

W3_vmass=P_v/P*m_air "Using wrong relation"

14-149 A room contains 65 kg of dry air and 0.6 kg of water vapor at 25°C and 90 kPa total pressure. The relative humidity of air in the room is

- (a) 3.5% (b) 41.5% (c) 55.2% (d) 60.9% (e) 73.0%

Answer (b) 41.5%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=25 "C"
P=90 "kPa"
m_air=65 "kg"
m_v=0.6 "kg"
w=0.622*P_v/(P-P_v)
w=m_v/m_air
P_g=PRESSURE(Steam_IAPWS,T=T1,x=0)
RH=P_v/P_g
```

14-153 On the psychrometric chart, a cooling and dehumidification process appears as a line that is

- (a) horizontal to the left,
- (b) vertical downward,
- (c) diagonal upwards to the right (NE direction)
- (d) diagonal upwards to the left (NW direction)
- (e) diagonal downwards to the left (SW direction)

Answer (e) diagonal downwards to the left (SW direction)

14-154 On the psychrometric chart, a heating and humidification process appears as a line that is

- (a) horizontal to the right,
- (b) vertical upward,
- (c) diagonal upwards to the right (NE direction)
- (d) diagonal upwards to the left (NW direction)
- (e) diagonal downwards to the right (SE direction)

Answer (c) diagonal upwards to the right (NE direction)

14-155 An air stream at a specified temperature and relative humidity undergoes evaporative cooling by spraying water into it at about the same temperature. The lowest temperature the air stream can be cooled to is

- (a) the dry bulb temperature at the given state
- (b) the wet bulb temperature at the given state
- (c) the dew point temperature at the given state
- (d) the saturation temperature corresponding to the humidity ratio at the given state
- (e) the triple point temperature of water

Answer (a) the dry bulb temperature at the given state

14-156 Air is cooled and dehumidified as it flows over the coils of a refrigeration system at 85 kPa from 35°C and a humidity ratio of 0.023 kg/kg dry air to 15°C and a humidity ratio of 0.015 kg/kg dry air. If the mass flow rate of dry air is 0.4 kg/s, the rate of heat removal from the air is

- (a) 4 kJ/s
- (b) 8 kJ/s
- (c) 12 kJ/s
- (d) 16 kJ/s
- (e) 20 kJ/s

Answer (d) 16 kJ/s

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P=85 "kPa"
T1=35 "C"

Fuels and Combustion

15-1C Nitrogen, in general, does not react with other chemical species during a combustion process but its presence affects the outcome of the process because nitrogen absorbs a large proportion of the heat released during the chemical process.

15-2C Moisture, in general, does not react chemically with any of the species present in the combustion chamber, but it absorbs some of the energy released during combustion, and it raises the dew point temperature of the combustion gases.

15-3C The number of atoms are preserved during a chemical reaction, but the total mole numbers are not.

15-4C Air-fuel ratio is the ratio of the mass of air to the mass of fuel during a combustion process. Fuel-air ratio is the inverse of the air-fuel ratio.

15-5C No. Because the molar mass of the fuel and the molar mass of the air, in general, are different.

15-6C The dew-point temperature of the product gases is the temperature at which the water vapor in the product gases starts to condense as the gases are cooled at constant pressure. It is the saturation temperature corresponding to the vapor pressure of the product gases.

15-7 Sulfur is burned with oxygen to form sulfur dioxide. The minimum mass of oxygen required and the mass of sulfur dioxide in the products are to be determined when 1 kg of sulfur is burned.

Properties The molar masses of sulfur and oxygen are 32.06 kg/kmol and 32.00 kg/kmol, respectively (Table A-1).

Analysis The chemical reaction is given by

Hence, 1 kmol of oxygen is required to burn 1 kmol of sulfur which produces 1 kmol of sulfur dioxide whose molecular weight is

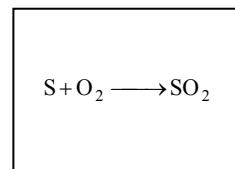

$$M_{\text{SO}_2} = M_{\text{S}} + M_{\text{O}_2} = 32.06 + 32.00 = 64.06 \text{ kg/kmol}$$

Then,

$$\frac{m_{\text{O}_2}}{m_{\text{S}}} = \frac{N_{\text{O}_2} M_{\text{O}_2}}{N_{\text{S}} M_{\text{S}}} = \frac{(1 \text{ kmol})(32 \text{ kg/kmol})}{(1 \text{ kmol})(32.06 \text{ kg/kmol})} = \mathbf{0.998 \text{ kg O}_2/\text{kg S}}$$

and

$$\frac{m_{\text{SO}_2}}{m_{\text{S}}} = \frac{N_{\text{SO}_2} M_{\text{SO}_2}}{N_{\text{S}} M_{\text{S}}} = \frac{(1 \text{ kmol})(64.06 \text{ kg/kmol})}{(1 \text{ kmol})(32.06 \text{ kg/kmol})} = \mathbf{1.998 \text{ kg SO}_2/\text{kg S}}$$

15-8E Methane is burned with diatomic oxygen. The mass of water vapor in the products is to be determined when 1 lbm of methane is burned.

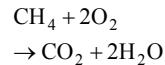

Properties The molar masses of CH₄, O₂, CO₂, and H₂O are 16, 32, 44, and 18 lbm/lbmol, respectively (Table A-1E).

Analysis The chemical reaction is given by

Hence, for each lbmol of methane burned, 2 lbmol of water vapor are formed. Then,

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{CH}_4}} = \frac{N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}}}{N_{\text{CH}_4} M_{\text{CH}_4}} = \frac{(2 \text{ lbmol})(18 \text{ lbm/lbmol})}{(1 \text{ lbmol})(16 \text{ lbm/lbmol})} = \mathbf{2.25 \text{ lbm H}_2\text{O/lbm CH}_4}$$

Theoretical and Actual Combustion Processes

15-9C It represent the amount of air that contains the exact amount of oxygen needed for complete combustion.

15-10C No. The theoretical combustion is also complete, but the products of theoretical combustion does not contain any uncombined oxygen.

15-11C Case (b).

15-12C The causes of incomplete combustion are insufficient time, insufficient oxygen, insufficient mixing, and dissociation.

15-13C CO. Because oxygen is more strongly attracted to hydrogen than it is to carbon, and hydrogen is usually burned to completion even when there is a deficiency of oxygen.

15-14 Propane is burned with theoretical amount of air. The mass fraction of carbon dioxide and the mole and mass fractions of the water vapor in the products are to be determined.

Properties The molar masses of C₃H₈, O₂, N₂, CO₂, and H₂O are 44, 32, 28, 44, and 18 kg/kmol, respectively (Table A-1).

Analysis (a) The reaction in terms of undetermined coefficients is

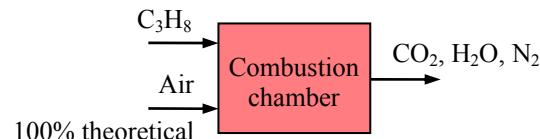

Balancing the carbon in this reaction gives

$$y = 3$$

and the hydrogen balance gives

$$2z = 8 \longrightarrow z = 4$$

The oxygen balance produces

$$2x = 2y + z \longrightarrow x = y + z / 2 = 3 + 4 / 2 = 5$$

A balance of the nitrogen in this reaction gives

$$2 \times 3.76x = 2p \longrightarrow p = 3.76x = 3.76 \times 5 = 18.8$$

In balanced form, the reaction is

The mass fraction of carbon dioxide is determined from

$$\begin{aligned} \text{mf}_{\text{CO}_2} &= \frac{m_{\text{CO}_2}}{m_{\text{products}}} = \frac{N_{\text{CO}_2} M_{\text{CO}_2}}{N_{\text{CO}_2} M_{\text{CO}_2} + N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} + N_{\text{N}_2} M_{\text{N}_2}} \\ &= \frac{(3 \text{ kmol})(44 \text{ kg/kmol})}{(3 \text{ kmol})(44 \text{ kg/kmol}) + (4 \text{ kmol})(18 \text{ kg/kmol}) + (18.8 \text{ kmol})(28 \text{ kg/kmol})} \\ &= \frac{132 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.181} \end{aligned}$$

(b) The mole and mass fractions of water vapor are

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{products}}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{CO}_2} + N_{\text{H}_2\text{O}} + N_{\text{N}_2}} = \frac{4 \text{ kmol}}{3 \text{ kmol} + 4 \text{ kmol} + 18.8 \text{ kmol}} = \frac{4 \text{ kmol}}{25.8 \text{ kmol}} = \mathbf{0.155}$$

$$\begin{aligned} \text{mf}_{\text{H}_2\text{O}} &= \frac{m_{\text{H}_2\text{O}}}{m_{\text{products}}} = \frac{N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}}}{N_{\text{CO}_2} M_{\text{CO}_2} + N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} + N_{\text{N}_2} M_{\text{N}_2}} \\ &= \frac{(4 \text{ kmol})(18 \text{ kg/kmol})}{(3 \text{ kmol})(44 \text{ kg/kmol}) + (4 \text{ kmol})(18 \text{ kg/kmol}) + (18.8 \text{ kmol})(28 \text{ kg/kmol})} \\ &= \frac{72 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.0986} \end{aligned}$$

15-15 Methane is burned with air. The mass flow rates at the two inlets are to be determined.

Properties The molar masses of CH₄, O₂, N₂, CO₂, and H₂O are 16, 32, 28, 44, and 18 kg/kmol, respectively (Table A-1).

Analysis The stoichiometric combustion equation of CH₄ is

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

$$\text{Substituting, } \text{CH}_4 + 2[\text{O}_2 + 3.76\text{N}_2] \longrightarrow \text{CO}_2 + 2\text{H}_2\text{O} + 7.52\text{N}_2$$

The masses of the reactants are

$$m_{\text{CH}_4} = N_{\text{CH}_4} M_{\text{CH}_4} = (1 \text{ kmol})(16 \text{ kg/kmol}) = 16 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (2 \text{ kmol})(32 \text{ kg/kmol}) = 64 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (2 \times 3.76 \text{ kmol})(28 \text{ kg/kmol}) = 211 \text{ kg}$$

The total mass is

$$m_{\text{total}} = m_{\text{CH}_4} + m_{\text{O}_2} + m_{\text{N}_2} = 16 + 64 + 211 = 291 \text{ kg}$$

Then the mass fractions are

$$mf_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{m_{\text{total}}} = \frac{16 \text{ kg}}{291 \text{ kg}} = 0.05498$$

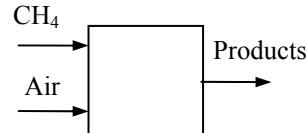

$$mf_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{64 \text{ kg}}{291 \text{ kg}} = 0.2199$$

$$mf_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{211 \text{ kg}}{291 \text{ kg}} = 0.7251$$

For a mixture flow of 0.5 kg/s, the mass flow rates of the reactants are

$$\dot{m}_{\text{CH}_4} = mf_{\text{CH}_4} \dot{m} = (0.05498)(0.5 \text{ kg/s}) = \mathbf{0.02749 \text{ kg/s}}$$

$$\dot{m}_{\text{air}} = \dot{m} - \dot{m}_{\text{CH}_4} = 0.5 - 0.02749 = \mathbf{0.4725 \text{ kg/s}}$$

15-16 n-Butane is burned with stoichiometric amount of oxygen. The mole fractions of CO₂ water in the products and the mole number of CO₂ in the products per mole of fuel burned are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂ and H₂O. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, and O₂ are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case is

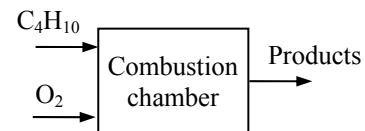

The total mole of the products are 4+5 = 9 kmol. Then the mole fractions are

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{total}}} = \frac{4 \text{ kmol}}{9 \text{ kmol}} = \mathbf{0.4444}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{5 \text{ kmol}}{9 \text{ kmol}} = \mathbf{0.5556}$$

$$\text{Also, } N_{\text{CO}_2} = \mathbf{4 \text{ kmol CO}_2/\text{kmol C}_4\text{H}_{10}}$$

15-17 Propane is burned with stoichiometric amount of air. The mass fraction of each product, the mass of water and air per unit mass of fuel burned are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 100% theoretical air is

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance: } B = 3$$

$$\text{Hydrogen balance: } 2D = 8 \longrightarrow D = 4$$

$$\text{Oxygen balance: } 2a_{\text{th}} = 2B + D \longrightarrow a_{\text{th}} = 0.5(2 \times 3 + 4) = 5$$

$$\text{Nitrogen balance: } a_{\text{th}} \times 3.76 = E \longrightarrow E = 5 \times 3.76 = 18.8$$

Substituting, the balanced reaction equation is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (3 \text{ kmol})(44 \text{ kg/kmol}) = 132 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (4 \text{ kmol})(18 \text{ kg/kmol}) = 72 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (18.8 \text{ kmol})(28 \text{ kg/kmol}) = 526.4 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} + m_{\text{N}_2} = 132 + 72 + 526.4 = 730.4 \text{ kg}$$

Then the mass fractions are

$$mf_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{132 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.1807}$$

$$mf_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{72 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.0986}$$

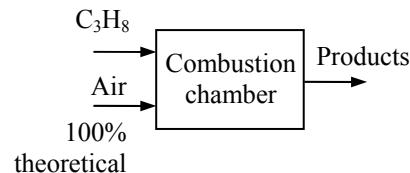

$$mf_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{526.4 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.7207}$$

The mass of water per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_3\text{H}_8}} = \frac{(4 \times 18) \text{ kg}}{(1 \times 44) \text{ kg}} = \mathbf{1.636 \text{ kg H}_2\text{O/kg C}_3\text{H}_8}$$

The mass of air required per unit mass of fuel burned is

$$\frac{m_{\text{air}}}{m_{\text{C}_3\text{H}_8}} = \frac{(5 \times 4.76 \times 29) \text{ kg}}{(1 \times 44) \text{ kg}} = \mathbf{15.69 \text{ kg air/kg C}_3\text{H}_8}$$

15-18 n-Octane is burned with stoichiometric amount of air. The mass fraction of each product, the mass of water in the products and the mass fraction of each reactant are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 100% theoretical air is

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance: } B = 8$$

$$\text{Hydrogen balance: } 2D = 18 \longrightarrow D = 9$$

$$\text{Oxygen balance: } 2a_{\text{th}} = 2B + D \longrightarrow a_{\text{th}} = 0.5(2 \times 8 + 9) = 12.5$$

$$\text{Nitrogen balance: } a_{\text{th}} \times 3.76 = E \longrightarrow E = 12.5 \times 3.76 = 47$$

Substituting, the balanced reaction equation is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (8 \text{ kmol})(44 \text{ kg/kmol}) = 352 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (9 \text{ kmol})(18 \text{ kg/kmol}) = 162 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (47 \text{ kmol})(28 \text{ kg/kmol}) = 1316 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{N}_2} + m_{\text{H}_2\text{O}} = 352 + 162 + 1316 = 1830 \text{ kg}$$

Then the mass fractions are

$$mf_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{352 \text{ kg}}{1830 \text{ kg}} = \mathbf{0.1923}$$

$$mf_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{162 \text{ kg}}{1830 \text{ kg}} = \mathbf{0.0885}$$

$$mf_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1316 \text{ kg}}{1830 \text{ kg}} = \mathbf{0.7191}$$

The mass of water per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_8\text{H}_{18}}} = \frac{(9 \times 18) \text{ kg}}{(1 \times 114) \text{ kg}} = \mathbf{1.421 \text{ kg H}_2\text{O/kg C}_8\text{H}_{18}}$$

The mass of each reactant and the total mass are

$$m_{\text{C}_8\text{H}_{18}} = N_{\text{C}_8\text{H}_{18}} M_{\text{C}_8\text{H}_{18}} = (1 \text{ kmol})(114 \text{ kg/kmol}) = 114 \text{ kg}$$

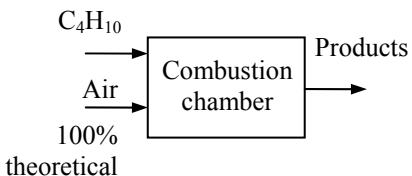

$$m_{\text{air}} = N_{\text{air}} M_{\text{air}} = (12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 1725.5 \text{ kg}$$

$$m_{\text{total}} = m_{\text{C}_8\text{H}_{18}} + m_{\text{air}} = 114 + 1725.5 = 1839.5 \text{ kg}$$

Then the mass fractions of reactants are

$$mf_{\text{C}_8\text{H}_{18}} = \frac{m_{\text{C}_8\text{H}_{18}}}{m_{\text{total}}} = \frac{114 \text{ kg}}{1839.5 \text{ kg}} = \mathbf{0.0620}$$

$$mf_{\text{air}} = \frac{m_{\text{air}}}{m_{\text{total}}} = \frac{1725.5 \text{ kg}}{1839.5 \text{ kg}} = \mathbf{0.9380}$$

15-19 Acetylene is burned with 10 percent excess oxygen. The mass fractions of each of the products and the mass of oxygen used per unit mass of fuel burned are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and O₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, and O₂ are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

Analysis The stoichiometric combustion equation is

The combustion equation with 10% excess oxygen is

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (2 \text{ kmol})(44 \text{ kg/kmol}) = 88 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (1 \text{ kmol})(18 \text{ kg/kmol}) = 18 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (0.25 \text{ kmol})(32 \text{ kg/kmol}) = 8 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} + m_{\text{O}_2} = 88 + 18 + 8 = 114 \text{ kg}$$

Then the mass fractions are

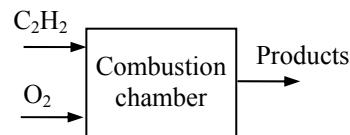

$$mf_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{88 \text{ kg}}{114 \text{ kg}} = \mathbf{0.7719}$$

$$mf_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{18 \text{ kg}}{114 \text{ kg}} = \mathbf{0.1579}$$

$$mf_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{8 \text{ kg}}{114 \text{ kg}} = \mathbf{0.0702}$$

The mass of oxygen per unit mass of fuel burned is determined from

$$\frac{m_{\text{O}_2}}{m_{\text{C}_2\text{H}_2}} = \frac{(2.75 \times 32) \text{ kg}}{(1 \times 26) \text{ kg}} = \mathbf{3.385 \text{ kg O}_2/\text{kg C}_2\text{H}_2}$$

15-20 n-Butane is burned with 100 percent excess air. The mole fractions of each of the products, the mass of carbon dioxide in the products per unit mass of the fuel, and the air-fuel ratio are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 100% excess air by using the factor $2.0a_{\text{th}}$ instead of a_{th} for air. The stoichiometric amount of oxygen ($a_{\text{th}}\text{O}_2$) will be used to oxidize the fuel, and the remaining excess amount ($1.0a_{\text{th}}\text{O}_2$) will appear in the products as free oxygen. The coefficient a_{th} is determined from the O₂ balance,

$$\text{O}_2 \text{ balance: } 2.0a_{\text{th}} = 4 + 2.5 + 1.0a_{\text{th}} \longrightarrow a_{\text{th}} = 6.5$$

The mole fractions of the products are

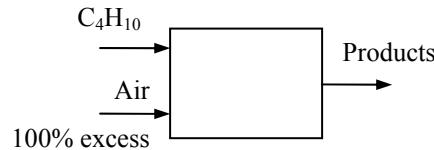

$$N_m = 4 + 5 + 6.5 + 48.88 = 64.38 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{4 \text{ kmol}}{64.38 \text{ kmol}} = \mathbf{0.0621}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{5 \text{ kmol}}{64.38 \text{ kmol}} = \mathbf{0.0777}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{6.5 \text{ kmol}}{64.38 \text{ kmol}} = \mathbf{0.1010}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{48.88 \text{ kmol}}{64.38 \text{ kmol}} = \mathbf{0.7592}$$

The mass of carbon dioxide in the products per unit mass of fuel burned is

$$\frac{m_{\text{CO}_2}}{m_{\text{C}_4\text{H}_{10}}} = \frac{(4 \times 44) \text{ kg}}{(1 \times 58) \text{ kg}} = \mathbf{3.034 \text{ kg CO}_2/\text{kg C}_4\text{H}_{10}}$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(13 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(58 \text{ kg/kmol})} = \mathbf{30.94 \text{ kg air/kg fuel}}$$

15-21 n-Octane is burned with 50 percent excess air. The mole fractions of each of the products, the mass of water in the products per unit mass of the fuel, and the mass fraction of each reactant are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 50% excess air by using the factor $1.5a_{\text{th}}$ instead of a_{th} for air. The stoichiometric amount of oxygen ($a_{\text{th}}\text{O}_2$) will be used to oxidize the fuel, and the remaining excess amount ($0.5a_{\text{th}}\text{O}_2$) will appear in the products as free oxygen. The coefficient a_{th} is determined from the O₂ balance,

$$\text{O}_2 \text{ balance: } 1.5a_{\text{th}} = 8 + 4.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

The mass of each product and the total mass are

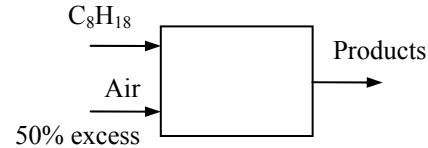

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (8 \text{ kmol})(44 \text{ kg/kmol}) = 352 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (9 \text{ kmol})(18 \text{ kg/kmol}) = 162 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (6.25 \text{ kmol})(32 \text{ kg/kmol}) = 200 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (70.5 \text{ kmol})(28 \text{ kg/kmol}) = 1974 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} + m_{\text{O}_2} + m_{\text{N}_2} = 352 + 162 + 200 + 1974 = 2688 \text{ kg}$$

Then the mass fractions are

$$mf_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{352 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.1310}$$

$$mf_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{162 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.0603}$$

$$mf_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{200 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.0744}$$

$$mf_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1974 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.7344}$$

The mass of water per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_8\text{H}_{18}}} = \frac{(9 \times 18) \text{ kg}}{(1 \times 114) \text{ kg}} = \mathbf{1.421 \text{ kg H}_2\text{O/kg C}_8\text{H}_{18}}$$

The mass of each reactant and the total mass are

$$m_{\text{C}_8\text{H}_{18}} = N_{\text{C}_8\text{H}_{18}} M_{\text{C}_8\text{H}_{18}} = (1 \text{ kmol})(114 \text{ kg/kmol}) = 114 \text{ kg}$$

$$m_{\text{air}} = N_{\text{air}} M_{\text{air}} = (17.75 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 2588 \text{ kg}$$

$$m_{\text{total}} = m_{\text{C}_8\text{H}_{18}} + m_{\text{air}} = 114 + 2588 = 2702 \text{ kg}$$

Then the mass fractions of reactants are

$$mf_{\text{C}_8\text{H}_{18}} = \frac{m_{\text{C}_8\text{H}_{18}}}{m_{\text{total}}} = \frac{114 \text{ kg}}{2702 \text{ kg}} = \mathbf{0.0422}$$

$$mf_{\text{air}} = \frac{m_{\text{air}}}{m_{\text{total}}} = \frac{2588 \text{ kg}}{2702 \text{ kg}} = \mathbf{0.9578}$$

15-22 Ethyl alcohol is burned with 70% excess air. The mole fractions of the products and the reactants, the mass of water and oxygen in products per unit mass of fuel are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction with stoichiometric air is

where $0.5 + a_{th} = 2 + 1.5 \longrightarrow a_{th} = 3$

Substituting,

The reaction with 70% excess air can be written as

The coefficient x is determined from O₂ balance:

$$0.5 + 1.7 \times 3 = 2 + 1.5 + x \longrightarrow x = 2.1$$

The total moles of the products is

$$N_m = 2 + 3 + 2.1 + 19.18 = 26.28 \text{ kmol}$$

The mole fractions of the products are

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{2 \text{ kmol}}{26.28 \text{ kmol}} = \mathbf{0.0761}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_m} = \frac{3 \text{ kmol}}{26.28 \text{ kmol}} = \mathbf{0.1142}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{2.1 \text{ kmol}}{26.28 \text{ kmol}} = \mathbf{0.0799}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{19.18 \text{ kmol}}{26.28 \text{ kmol}} = \mathbf{0.7298}$$

The total moles of the reactants is

$$N_m = 1 + 5.1 \times 4.76 = 25.28 \text{ kmol}$$

The mole fractions of the reactants are

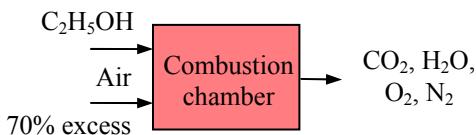

$$y_{\text{C}_2\text{H}_5\text{OH}} = \frac{N_{\text{C}_2\text{H}_5\text{OH}}}{N_m} = \frac{1 \text{ kmol}}{25.28 \text{ kmol}} = \mathbf{0.0396}$$

$$y_{\text{air}} = \frac{N_{\text{air}}}{N_m} = \frac{(5.1 \times 4.76) \text{ kmol}}{25.28 \text{ kmol}} = \mathbf{0.9603}$$

The mass of water and oxygen in the products per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_2\text{H}_5\text{OH}}} = \frac{(3 \times 18) \text{ kg}}{(1 \times 46) \text{ kg}} = \mathbf{1.174 \text{ kg H}_2\text{O/kg C}_2\text{H}_5\text{OH}}$$

$$\frac{m_{\text{O}_2}}{m_{\text{C}_2\text{H}_5\text{OH}}} = \frac{(2.1 \times 32) \text{ kg}}{(1 \times 46) \text{ kg}} = \mathbf{1.461 \text{ kg O}_2/\text{kg C}_2\text{H}_5\text{OH}}$$

15-23 Ethyl alcohol is burned with 70% excess air. The air-fuel ratio is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction with stoichiometric air is

where

$$0.5 + a_{th} = 2 + 1.5 \longrightarrow a_{th} = 3$$

Substituting,

The reaction with 70% excess air can be written as

The coefficient x is determined from O₂ balance:

$$0.5 + 1.7 \times 3 = 2 + 1.5 + x \longrightarrow x = 2.1$$

Then,

The air-fuel mass ratio is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(5.1 \times 4.76 \times 29) \text{ kg}}{(1 \times 46) \text{ kg}} = \frac{704.0 \text{ kg}}{46 \text{ kg}} = \mathbf{15.30 \text{ kg air/kg fuel}}$$

15-24 Gasoline is burned steadily with air in a jet engine. The AF ratio is given. The percentage of excess air used is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The theoretical combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

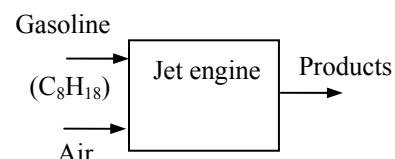

$$\text{O}_2 \text{ balance: } a_{th} = 8 + 4.5 \longrightarrow a_{th} = 12.5$$

The air-fuel ratio for the theoretical reaction is determined by taking the ratio of the mass of the air to the mass of the fuel for,

$$\text{AF}_{th} = \frac{m_{\text{air},th}}{m_{\text{fuel}}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(8 \text{ kmol})(12 \text{ kg/kmol}) + (9 \text{ kmol})(2 \text{ kg/kmol})} = 15.14 \text{ kg air/kg fuel}$$

Then the percent theoretical air used can be determined from

$$\text{Percent theoretical air} = \frac{\text{AF}_{act}}{\text{AF}_{th}} = \frac{18 \text{ kg air/kg fuel}}{15.14 \text{ kg air/kg fuel}} = \mathbf{119\%}$$

15-25E Ethylene is burned with 175 percent theoretical air during a combustion process. The AF ratio and the dew-point temperature of the products are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, and air are 12 lbm/lbmol, 2 lbm/lbmol, and 29 lbm/lbmol, respectively (Table A-1E).

Analysis (a) The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } 1.75a_{\text{th}} = 2 + 1 + 0.75a_{\text{th}} \longrightarrow a_{\text{th}} = 3$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

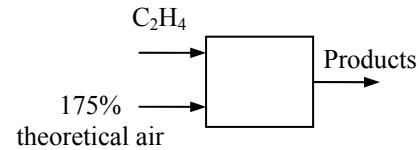

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(5.25 \times 4.76 \text{ lbmol})(29 \text{ lbm/lbmol})}{(2 \text{ lbmol})(12 \text{ lbm/lbmol}) + (2 \text{ lbmol})(2 \text{ lbm/lbmol})} = 25.9 \text{ lbm air/lbm fuel}$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{2 \text{ lbmol}}{25.99 \text{ lbmol}} \right) (14.5 \text{ psia}) = 1.116 \text{ psia}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@1.116 \text{ psia}} = 105.4^\circ\text{F}$$

15-26 Propylene is burned with 50 percent excess air during a combustion process. The AF ratio and the temperature at which the water vapor in the products will start condensing are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } 1.5a_{\text{th}} = 3 + 1.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 4.5$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

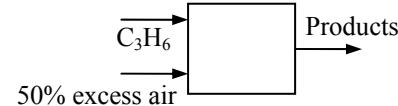

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(6.75 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (3 \text{ kmol})(2 \text{ kg/kmol})} = 22.2 \text{ kg air/kg fuel}$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{3 \text{ kmol}}{33.63 \text{ kmol}} \right) (105 \text{ kPa}) = 9.367 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@9.367 \text{ kPa}} = 44.5^\circ\text{C}$$

15-27 Butane C₄H₁₀ is burned with 200 percent theoretical air. The kmol of water that needs to be sprayed into the combustion chamber per kmol of fuel is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 200% theoretical air without the additional water is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 100% excess air by using the factor $2a_{\text{th}}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

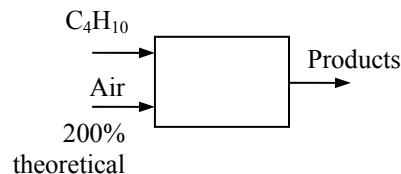

Carbon balance: $B = 4$

Hydrogen balance: $2D = 10 \longrightarrow D = 5$

Oxygen balance: $2 \times 2a_{\text{th}} = 2B + D + 2E$

$$a_{\text{th}} = E$$

Nitrogen balance: $2a_{\text{th}} \times 3.76 = F$

Solving the above equations, we find the coefficients ($E = 6.5$, $F = 48.88$, and $a_{\text{th}} = 6.5$) and write the balanced reaction equation as

With the additional water sprayed into the combustion chamber, the balanced reaction equation is

The partial pressure of water in the saturated product mixture at the dew point is

$$P_{v,\text{prod}} = P_{\text{sat}@60^\circ\text{C}} = 19.95 \text{ kPa}$$

The vapor mole fraction is

$$y_v = \frac{P_{v,\text{prod}}}{P_{\text{prod}}} = \frac{19.95 \text{ kPa}}{100 \text{ kPa}} = 0.1995$$

The amount of water that needs to be sprayed into the combustion chamber can be determined from

$$y_v = \frac{N_{\text{water}}}{N_{\text{total,product}}} \longrightarrow 0.1995 = \frac{5 + N_v}{4 + 5 + N_v + 6.5 + 48.88} \longrightarrow N_v = \mathbf{9.796 \text{ kmol}}$$

15-28 A fuel mixture of 60% by mass methane, CH₄, and 40% by mass ethanol, C₂H₆O, is burned completely with theoretical air. The required flow rate of air is to be determined.

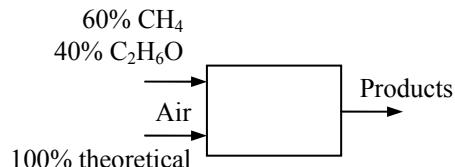

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis For 100 kg of fuel mixture, the mole numbers are

$$N_{\text{CH}_4} = \frac{mf_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_2\text{H}_6\text{O}} = \frac{mf_{\text{C}_2\text{H}_6\text{O}}}{M_{\text{C}_2\text{H}_6\text{O}}} = \frac{40 \text{ kg}}{46 \text{ kg/kmol}} = 0.8696 \text{ kmol}$$

The mole fraction of methane and ethanol in the fuel mixture are

$$x = \frac{N_{\text{CH}_4}}{N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6\text{O}}} = \frac{3.75 \text{ kmol}}{(3.75 + 0.8696) \text{ kmol}} = 0.8118$$

$$y = \frac{N_{\text{C}_2\text{H}_6\text{O}}}{N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6\text{O}}} = \frac{0.8696 \text{ kmol}}{(3.75 + 0.8696) \text{ kmol}} = 0.1882$$

The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance: } x + 2y = B$$

$$\text{Hydrogen balance: } 4x + 6y = 2D$$

$$\text{Oxygen balance: } 2a_{\text{th}} + y = 2B + D$$

$$\text{Nitrogen balance: } 3.76a_{\text{th}} = F$$

Substituting x and y values into the equations and solving, we find the coefficients as

$$x = 0.8118 \quad B = 1.188$$

$$y = 0.1882 \quad D = 2.188$$

$$a_{\text{th}} = 2.188 \quad F = 8.228$$

Then, we write the balanced reaction equation as

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\begin{aligned} AF &= \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(2.188 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(0.8118 \text{ kmol})(12 + 4 \times 1) \text{ kg/kmol} + (0.1882 \text{ kmol})(2 \times 12 + 6 \times 1 + 16) \text{ kg/kmol}} \\ &= 13.94 \text{ kg air/kg fuel} \end{aligned}$$

Then, the required flow rate of air becomes

$$\dot{m}_{\text{air}} = AF \dot{m}_{\text{fuel}} = (13.94)(10 \text{ kg/s}) = \mathbf{139.4 \text{ kg/s}}$$

15-29 The volumetric fractions of the constituents of a certain natural gas are given. The AF ratio is to be determined if this gas is burned with the stoichiometric amount of dry air.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, N₂, O₂, and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 1 kmol of fuel, the combustion equation can be written as

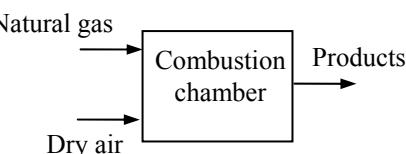

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.65 + 0.06 = x \longrightarrow x = 0.71$$

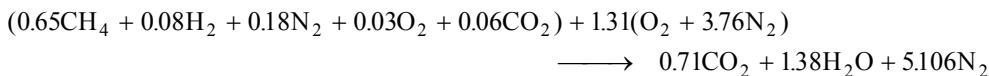

$$\text{H: } 0.65 \times 4 + 0.08 \times 2 = 2y \longrightarrow y = 1.38$$

$$\text{O}_2: 0.03 + 0.06 + a_{\text{th}} = x + y/2 \longrightarrow a_{\text{th}} = 1.31$$

$$\text{N}_2: 0.18 + 3.76a_{\text{th}} = z \longrightarrow z = 5.106$$

Thus,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.31 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 180.8 \text{ kg}$$

$$m_{\text{fuel}} = (0.65 \times 16 + 0.08 \times 2 + 0.18 \times 28 + 0.03 \times 32 + 0.06 \times 44) \text{ kg} = 19.2 \text{ kg}$$

and

$$\text{AF}_{\text{th}} = \frac{m_{\text{air},\text{th}}}{m_{\text{fuel}}} = \frac{180.8 \text{ kg}}{19.2 \text{ kg}} = \mathbf{9.42 \text{ kg air/kg fuel}}$$

15-30 The composition of a certain natural gas is given. The gas is burned with stoichiometric amount of moist air. The AF ratio is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, N₂, O₂, and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only H₂O, CO₂ and N₂, but no free O₂. The moisture in the air does not react with anything; it simply shows up as additional H₂O in the products. Therefore, we can simply balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of fuel, the combustion equation can be written as

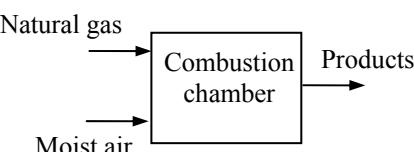

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.65 + 0.06 = x \longrightarrow x = 0.71$$

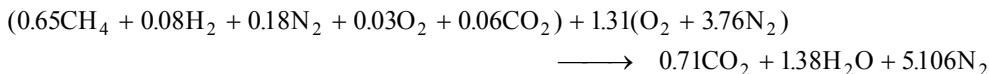

$$\text{H: } 0.65 \times 4 + 0.08 \times 2 = 2y \longrightarrow y = 1.38$$

$$\text{O}_2: 0.03 + 0.06 + a_{\text{th}} = x + y / 2 \longrightarrow a_{\text{th}} = 1.31$$

$$\text{N}_2: 0.18 + 3.76a_{\text{th}} = z \longrightarrow z = 5.106$$

Thus,

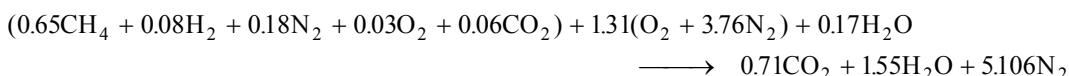

Next we determine the amount of moisture that accompanies $4.76a_{\text{th}} = (4.76)(1.31) = 6.24$ kmol of dry air. The partial pressure of the moisture in the air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@25^\circ\text{C}} = (0.85)(3.1698 \text{ kPa}) = 2.694 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture in the air ($N_{v,\text{in}}$) is determined to be

$$N_{v,\text{in}} = \left(\frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left(\frac{2.694 \text{ kPa}}{101.325 \text{ kPa}} \right) (6.24 + N_{v,\text{in}}) \longrightarrow N_{v,\text{air}} = 0.17 \text{ kmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.17 kmol of H₂O to both sides of the equation,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.31 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) + (0.17 \text{ kmol} \times 18 \text{ kg/kmol}) = 183.9 \text{ kg}$$

$$m_{\text{fuel}} = (0.65 \times 16 + 0.08 \times 2 + 0.18 \times 28 + 0.03 \times 32 + 0.06 \times 44) \text{ kg} = 19.2 \text{ kg}$$

and

$$\text{AF}_{\text{th}} = \frac{m_{\text{air},\text{th}}}{m_{\text{fuel}}} = \frac{183.9 \text{ kg}}{19.2 \text{ kg}} = \mathbf{9.58 \text{ kg air/kg fuel}}$$

15-31 The composition of a gaseous fuel is given. It is burned with 130 percent theoretical air. The AF ratio and the fraction of water vapor that would condense if the product gases were cooled are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

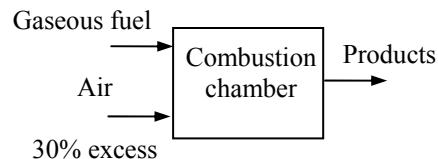

Properties The molar masses of C, H₂, N₂, and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The fuel is burned completely with excess air, and thus the products will contain H₂O, CO₂, N₂, and some free O₂. Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\begin{aligned} \text{C: } 0.45 &= x \longrightarrow x = 0.45 \\ \text{H: } 0.45 \times 4 + 0.35 \times 2 &= 2y \longrightarrow y = 1.2 \\ \text{O}_2: 1.3a_{\text{th}} &= x + y/2 + 0.3a_{\text{th}} \longrightarrow a_{\text{th}} = 1.05 \\ \text{N}_2: 0.20 + 3.76 \times 1.3a_{\text{th}} &= z \longrightarrow z = 5.332 \end{aligned}$$

Thus,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\begin{aligned} m_{\text{air}} &= (1.365 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 188.4 \text{ kg} \\ m_{\text{fuel}} &= (0.45 \times 16 + 0.35 \times 2 + 0.2 \times 28) \text{ kg} = 13.5 \text{ kg} \end{aligned}$$

and

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{188.4 \text{ kg}}{13.5 \text{ kg}} = \mathbf{13.96 \text{ kg air/kg fuel}}$$

(b) For each kmol of fuel burned, 0.45 + 1.2 + 0.315 + 5.332 = 7.297 kmol of products are formed, including 1.2 kmol of H₂O. Assuming that the dew-point temperature of the products is above 25°C, some of the water vapor will condense as the products are cooled to 25°C. If N_w kmol of H₂O condenses, there will be 1.2 - N_w kmol of water vapor left in the products. The mole number of the products in the gas phase will also decrease to 7.297 - N_w as a result. Treating the product gases (including the remaining water vapor) as ideal gases, N_w is determined by equating the mole fraction of the water vapor to its pressure fraction,

$$\frac{N_v}{N_{\text{prod,gas}}} = \frac{P_v}{P_{\text{prod}}} \longrightarrow \frac{1.2 - N_w}{7.297 - N_w} = \frac{3.1698 \text{ kPa}}{101.325 \text{ kPa}} \longrightarrow N_w = 1.003 \text{ kmol}$$

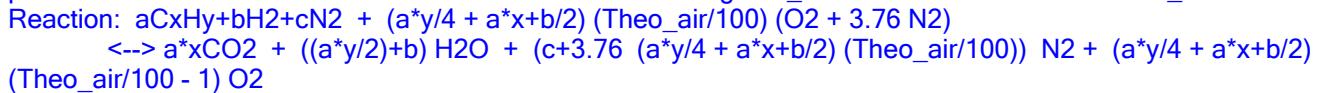

since P_v = P_{sat @ 25°C} = 3.1698 kPa. Thus the fraction of water vapor that condenses is 1.003/1.2 = 0.836 or **84%**.

15-32 Problem 15-31 is reconsidered. The effects of varying the percentages of CH₄, H₂ and N₂ making up the fuel and the product gas temperature are to be studied.

Analysis The problem is solved using EES, and the solution is given below.

Let's modify this problem to include the fuels butane, ethane, methane, and propane in pull down menu. Adiabatic Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air}:

T_{prod} is the product gas temperature.

Theo_air is the % theoretical air. "

Procedure

15-33 Carbon is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, O₂, and N₂ only.

Properties The molar masses of C, H₂, and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

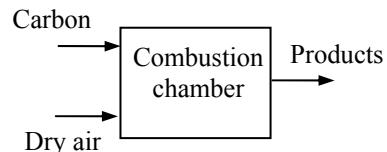

The unknown coefficients x and a are determined from mass balances,

$$N_2 : 3.76a = 78.83 \longrightarrow a = 20.965$$

$$C : x = 10.06 + 0.42 \longrightarrow x = 10.48$$

$$(Check O_2 : a = 10.06 + 0.21 + 10.69 \longrightarrow 20.96 = 20.96)$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 10.48,

(a) The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(2.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(12 \text{ kg/kmol})} = \mathbf{23.0 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

Then,

$$\text{Percent theoretical air} = \frac{m_{air,act}}{m_{air,th}} = \frac{N_{air,act}}{N_{air,th}} = \frac{(2.0)(4.76) \text{ kmol}}{(1.0)(4.76) \text{ kmol}} = \mathbf{200\%}$$

15-34 Methane is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

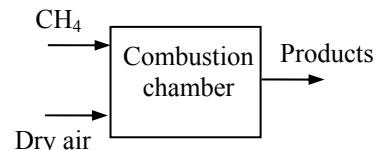

The unknown coefficients x , a , and b are determined from mass balances,

$$\text{N}_2 : 3.76a = 83.23 \longrightarrow a = 22.14$$

$$\text{C} : x = 5.20 + 0.33 \longrightarrow x = 5.53$$

$$\text{H} : 4x = 2b \longrightarrow b = 11.06$$

$$(\text{Check } \text{O}_2 : a = 5.20 + 0.165 + 11.24 + b/2 \longrightarrow 22.14 = 22.14)$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.53,

(a) The air-fuel ratio is determined from its definition,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(4.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(12 \text{ kg/kmol}) + (2 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{34.5 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2 : a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2.0$$

Then,

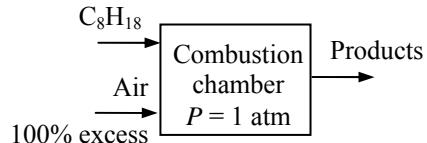

$$\text{Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(4.0)(4.76) \text{ kmol}}{(2.0)(4.76) \text{ kmol}} = \mathbf{200\%}$$

15-35 n-Octane is burned with 100% excess air. The combustion is incomplete. The mole fractions of products and the dew-point temperature of the water vapor in the products are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction for stoichiometric air is

The combustion equation with 100% excess air and incomplete combustion is

The coefficient for CO is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 25 = 0.85 \times 8 + 0.15 \times 8 + 0.5 \times 9 + x \longrightarrow x = 13.1$$

Substituting,

The mole fractions of the products are

$$N_{\text{prod}} = 6.8 + 1.2 + 9 + 13.1 + 94 = 124.1 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{prod}}} = \frac{6.8 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.0548}$$

$$y_{\text{CO}} = \frac{N_{\text{CO}}}{N_{\text{prod}}} = \frac{1.2 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.0097}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{9 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.0725}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{prod}}} = \frac{13.1 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.1056}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{prod}}} = \frac{94 \text{ kmol}}{124.1 \text{ kmol}} = \mathbf{0.7575}$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{9 \text{ kmol}}{124.1 \text{ kmol}} \right) (101.325 \text{ kPa}) = 7.348 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@7.348 \text{ kPa}} = \mathbf{39.9^\circ\text{C}} \quad (\text{Table A-5 or EES})$$

15-36 Methyl alcohol is burned with 100% excess air. The combustion is incomplete. The balanced chemical reaction is to be written and the air-fuel ratio is to be determined.

Assumptions 1 Combustion is incomplete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O₂ balance:

$$0.5 + a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 1.5$$

Substituting,

The reaction with 100% excess air and incomplete combustion can be written as

The coefficient for O₂ is determined from a mass balance,

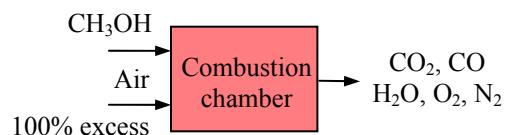

$$\text{O}_2 \text{ balance: } 0.5 + 2 \times 1.5 = 0.6 + 0.2 + 1 + x \longrightarrow x = 1.7$$

Substituting,

The air-fuel mass ratio is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(3 \times 4.76 \times 29) \text{ kg}}{(1 \times 32) \text{ kg}} = \frac{414.1 \text{ kg}}{32 \text{ kg}} = \mathbf{12.94 \text{ kg air/kg fuel}}$$

15-37 Ethyl alcohol is burned with stoichiometric amount of air. The combustion is incomplete. The apparent molecular weight of the products is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, OH, and N₂ only.

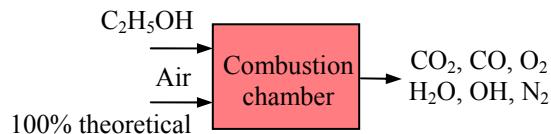

Properties The molar masses of C, H₂, OH, N₂ and air are 12 kg/kmol, 2 kg/kmol, 17 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction with stoichiometric air is

where

$$0.5 + a_{th} = 2 + 1.5 \longrightarrow a_{th} = 3$$

Substituting,

The balanced reaction equation with incomplete combustion is

$$\text{O}_2 \text{ balance: } 0.5 + 3 = 1.8 + 0.1 + 3.15/2 + b \rightarrow b = 0.025$$

which can be written as

The total moles of the products is

$$N_m = 1.8 + 0.2 + 2.85 + 0.3 + 0.025 + 11.28 = 16.64 \text{ kmol}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{(1.8 \times 44 + 0.20 \times 28 + 2.85 \times 18 + 0.3 \times 17 + 0.025 \times 32 + 11.28 \times 28) \text{ kg}}{16.64 \text{ kmol}} = \mathbf{27.83 \text{ kg/kmol}}$$

15-38 Coal whose mass percentages are specified is burned with stoichiometric amount of air. The mass fractions of the products and the air-fuel ratio are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, SO₂, and N₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, O₂, S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{79.61 \text{ kg}}{12 \text{ kg/kmol}} = 6.634 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{4.66 \text{ kg}}{2 \text{ kg/kmol}} = 2.33 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{4.76 \text{ kg}}{32 \text{ kg/kmol}} = 0.1488 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1.83 \text{ kg}}{28 \text{ kg/kmol}} = 0.06536 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.52 \text{ kg}}{32 \text{ kg/kmol}} = 0.01625 \text{ kmol}$$

79.61% C
4.66% H ₂
4.76% O ₂
1.83% N ₂
0.52% S
8.62% ash (by mass)

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

Performing mass balances for the constituents gives

$$\text{C balance: } x = 6.634$$

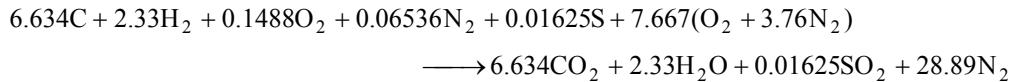

$$\text{H}_2 \text{ balance: } y = 2.33$$

$$\text{S balance: } z = 0.01625$$

$$\text{O}_2 \text{ balance: } 0.1488 + a_{th} = x + 0.5y + z \longrightarrow a_{th} = 6.634 + 0.5(2.33) + 0.01625 - 0.1488 = 7.667$$

$$\text{N}_2 \text{ balance: } w = 0.06536 + 3.76a_{th} = 0.06536 + 3.76 \times 7.667 = 28.89$$

Substituting, the balanced combustion equation without the ash becomes

The mass fractions of the products are

$$m_{\text{total}} = 6.634 \times 44 + 2.33 \times 18 + 0.01625 \times 64 + 228.89 \times 28 = 1144 \text{ kg}$$

$$mf_{CO_2} = \frac{m_{CO_2}}{m_{\text{total}}} = \frac{(6.634 \times 44) \text{ kg}}{1144 \text{ kg}} = \mathbf{0.2552}$$

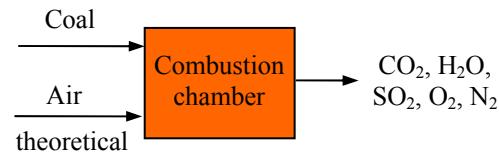

$$mf_{H_2O} = \frac{m_{H_2O}}{m_{\text{total}}} = \frac{(2.33 \times 18) \text{ kg}}{1144 \text{ kg}} = \mathbf{0.0367}$$

$$mf_{SO_2} = \frac{m_{SO_2}}{m_{\text{total}}} = \frac{(0.01625 \times 64) \text{ kg}}{1144 \text{ kg}} = \mathbf{0.00091}$$

$$mf_{N_2} = \frac{m_{N_2}}{m_{\text{total}}} = \frac{(28.89 \times 28) \text{ kg}}{1144 \text{ kg}} = \mathbf{0.7072}$$

The air-fuel mass ratio is then

$$AF = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(7.667 \times 4.76 \times 29) \text{ kg}}{(6.634 \times 12 + 2.33 \times 2 + 0.1488 \times 32 + 0.06536 \times 28 + 0.01625 \times 32) \text{ kg}} = \frac{1058 \text{ kg}}{91.38 \text{ kg}} = \mathbf{11.58 \text{ kg air/kg fuel}}$$

15-39 Coal whose mass percentages are specified is burned with 40% excess air. The air-fuel ratio and the apparent molecular weight of the product gas are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, SO₂, and N₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, O₂, S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{67.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.617 \text{ kmol}$$

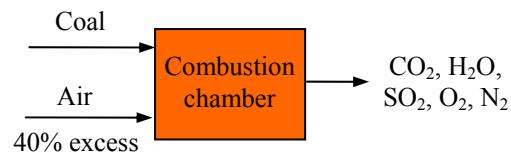

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.31 \text{ kg}}{2 \text{ kg/kmol}} = 2.655 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{15.11 \text{ kg}}{32 \text{ kg/kmol}} = 0.4722 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1.44 \text{ kg}}{28 \text{ kg/kmol}} = 0.05143 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{2.36 \text{ kg}}{32 \text{ kg/kmol}} = 0.07375 \text{ kmol}$$

67.40% C
5.31% H ₂
15.11% O ₂
1.44% N ₂
2.36% S
8.38% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.617 + 2.655 + 0.4722 + 0.05143 + 0.07375 = 8.869 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{5.617 \text{ kmol}}{8.869 \text{ kmol}} = 0.6333$$

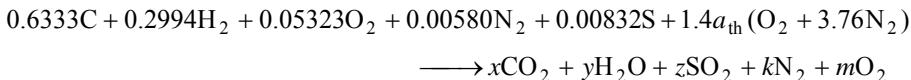

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.655 \text{ kmol}}{8.869 \text{ kmol}} = 0.2994$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.4722 \text{ kmol}}{8.869 \text{ kmol}} = 0.05323$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.05143 \text{ kmol}}{8.869 \text{ kmol}} = 0.00580$$

$$y_S = \frac{N_S}{N_m} = \frac{0.07375 \text{ kmol}}{8.869 \text{ kmol}} = 0.00832$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the species balances,

$$\text{C balance: } x = 0.6333$$

$$\text{H}_2 \text{ balance: } y = 0.2994$$

$$\text{S balance: } z = 0.00832$$

$$\text{O}_2 \text{ balance: }$$

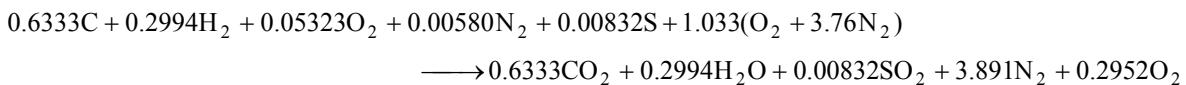

$$0.05323 + a_{th} = x + 0.5y + z$$

$$a_{th} = 0.6333 + 0.5 \times 0.2994 + 0.00832 - 0.05323 = 0.7381$$

$$\text{N}_2 \text{ balance: } k = 0.00580 + 1.4 \times 3.76a_{th} = 0.00580 + 1.4 \times 3.76 \times 0.7381 = 3.891$$

$$m = 0.4a_{th} = 0.4 \times 0.7381 = 0.2952$$

Substituting,

The total mass of the products is

$$m_{\text{total}} = 0.6333 \times 44 + 0.2994 \times 18 + 0.00832 \times 64 + 3.891 \times 28 + 0.2952 \times 32 = 152.2 \text{ kg}$$

The total mole number of the products is

$$N_m = 0.6333 + 0.2994 + 0.00832 + 3.891 + 0.2952 = 5.127 \text{ kmol}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{152.2 \text{ kg}}{5.127 \text{ kmol}} = \mathbf{29.68 \text{ kg/kmol}}$$

The air-fuel mass ratio is then

$$\begin{aligned} \text{AF} &= \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(1.033 \times 4.76 \times 29) \text{ kg}}{(0.6333 \times 12 + 0.2994 \times 2 + 0.05323 \times 32 + 0.00580 \times 28 + 0.00832 \times 32) \text{ kg}} \\ &= \frac{142.6 \text{ kg}}{10.33 \text{ kg}} \\ &= \mathbf{13.80 \text{ kg air/kg fuel}} \end{aligned}$$

Enthalpy of Formation and Enthalpy of Combustion

15-40C For combustion processes the enthalpy of reaction is referred to as the enthalpy of combustion, which represents the amount of heat released during a steady-flow combustion process.

15-41C Enthalpy of formation is the enthalpy of a substance due to its chemical composition. The enthalpy of formation is related to elements or compounds whereas the enthalpy of combustion is related to a particular fuel.

15-42C The heating value is called the higher heating value when the H₂O in the products is in the liquid form, and it is called the lower heating value when the H₂O in the products is in the vapor form. The heating value of a fuel is equal to the absolute value of the enthalpy of combustion of that fuel.

15-43C If the combustion of a fuel results in a single compound, the enthalpy of formation of that compound is identical to the enthalpy of combustion of that fuel.

15-44C Yes.

15-45C No. The enthalpy of formation of N₂ is simply assigned a value of zero at the standard reference state for convenience.

15-46C 1 kmol of H₂. This is evident from the observation that when chemical bonds of H₂ are destroyed to form H₂O a large amount of energy is released.

15-47 The enthalpy of combustion of methane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.

Analysis The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of CH₄ becomes

$$h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (\bar{h}_{f,\text{CO}_2}^\circ + \bar{h}_{f,\text{H}_2\text{O}}^\circ - \bar{h}_{f,\text{CH}_4}^\circ)$$

Using \bar{h}_f° values from Table A-26,

$$\begin{aligned} h_C &= (1 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (2 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-74,850 \text{ kJ/kmol}) \\ &= \mathbf{-890,330 \text{ kJ (per kmol CH}_4\text{)}} \end{aligned}$$

The listed value in Table A-27 is -890,868 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this h_c value corresponds to the higher heating value of CH₄.

15-48 Problem 15-47 is reconsidered. The effect of temperature on the enthalpy of combustion is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

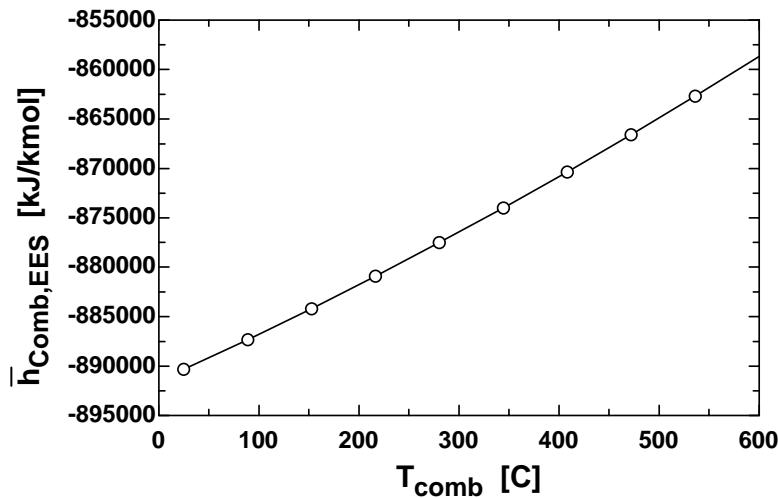

```

Fuel$ = 'Methane (CH4)'

15-49 Ethane is burned with stoichiometric amount of air. The heat transfer is to be determined if both the reactants and products are at 25°C.

Assumptions The water in the products is in the vapor phase.

Analysis The stoichiometric equation for this reaction is

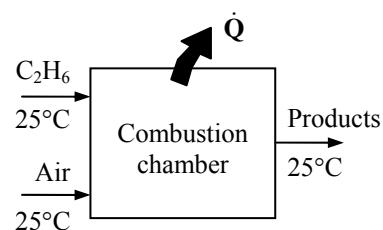

Since both the reactants and the products are at the standard reference state of 25°C and 1 atm, the heat transfer for this process is equal to enthalpy of combustion. Note that N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$Q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (\bar{h}_{f,C\text{O}_2}^\circ) + (\bar{h}_{f,\text{H}_2\text{O}}^\circ) - (\bar{h}_{f,\text{C}_2\text{H}_6}^\circ)$$

Using \bar{h}_f° values from Table A-26,

$$\begin{aligned} Q = h_C &= (2 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (3 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-84,680 \text{ kJ/kmol}) \\ &= \mathbf{-1,427,820 \text{ kJ/kmol C}_2\text{H}_6} \end{aligned}$$

15-50 Ethane is burned with stoichiometric amount of air at 1 atm and 25°C. The minimum pressure of the products which will assure that the water in the products will be in vapor form is to be determined.

Assumptions The water in the products is in the vapor phase.

Analysis The stoichiometric equation for this reaction is

At the minimum pressure, the product mixture will be saturated with water vapor and

$$P_v = P_{\text{sat}@25^\circ\text{C}} = 3.1698 \text{ kPa}$$

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{3 \text{ kmol}}{(2 + 3 + 13.16) \text{ kmol}} = 0.1652$$

The minimum pressure of the products is then

$$P_{\min} = \frac{P_v}{y_v} = \frac{3.1698 \text{ kPa}}{0.1652} = \mathbf{19.2 \text{ kPa}}$$

15-51 The higher and lower heating values of liquid propane are to be determined and compared to the listed values.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, O₂, H₂, and air are 12, 32, 2, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction with stoichiometric air is

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (\bar{h}_{f,CO_2}^\circ + \bar{h}_{f,H_2O}^\circ) - \bar{h}_{f,C_3H_8}^\circ$$

The \bar{h}_f° of liquid propane is obtained by adding \bar{h}_{fg} of propane at 25°C to \bar{h}_f° of gas propane (103,850 + 44.097 × 335 = 118,620 kJ/kmol). For the HHV, the water in the products is taken to be liquid. Then,

$$\begin{aligned} h_C &= (3 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (4 \text{ kmol})(-285,830 \text{ kJ/kmol}) - (1 \text{ kmol})(-118,620 \text{ kJ/kmol}) \\ &= -2,205,260 \text{ kJ/kmol} \text{ propane} \end{aligned}$$

The HHV of the liquid propane is

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{2,205,260 \text{ kJ/kmol C}_3\text{H}_8}{44.097 \text{ kg/kmol C}_3\text{H}_8} = \mathbf{50,010 \text{ kJ/kg C}_3\text{H}_8}$$

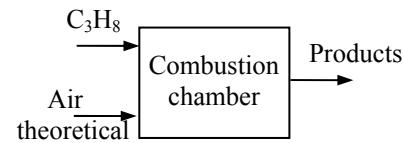

The listed value from Table A-27 is **50,330 kJ/kg**. For the LHV, the water in the products is taken to be vapor. Then,

$$\begin{aligned} h_C &= (3 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (4 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-118,620 \text{ kJ/kmol}) \\ &= -2,029,220 \text{ kJ/kmol} \text{ propane} \end{aligned}$$

The LHV of the propane is then

$$\text{LHV} = \frac{-h_C}{M_m} = \frac{2,029,220 \text{ kJ/kmol C}_3\text{H}_8}{44.097 \text{ kg/kmol C}_3\text{H}_8} = \mathbf{46,020 \text{ kJ/kg C}_3\text{H}_8}$$

The listed value from Table A-27 is **46,340 kJ/kg**. The calculated and listed values are practically identical.

15-52 The higher and lower heating values of gaseous octane are to be determined and compared to the listed values.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, O₂, H₂, and air are 12, 32, 2, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction with stoichiometric air is

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (\bar{h}_{f,\text{CO}_2}^\circ) + (\bar{h}_{f,\text{H}_2\text{O}}^\circ) - (\bar{h}_{f,\text{C}_8\text{H}_{18}}^\circ)$$

For the HHV, the water in the products is taken to be liquid. Then,

$$\begin{aligned} h_C &= (8 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (9 \text{ kmol})(-285,830 \text{ kJ/kmol}) - (1 \text{ kmol})(-208,450 \text{ kJ/kmol}) \\ &= -5,512,180 \text{ kJ/kmol} \text{ octane} \end{aligned}$$

The HHV of the gaseous octane is

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{5,512,180 \text{ kJ/kmol C}_8\text{H}_{18}}{114.231 \text{ kg/kmol C}_8\text{H}_{18}} = \mathbf{48,250 \text{ kJ/kg C}_8\text{H}_{18}}$$

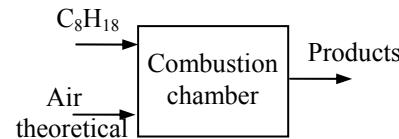

The listed value for liquid octane from Table A-27 is 47,890 kJ/kg. Adding the enthalpy of vaporization of octane to this value (47,890+363=48,253), the higher heating value of gaseous octane becomes **48,253 kJ/kg** octane. This value is practically identical to the calculated value. For the LHV, the water in the products is taken to be vapor. Then,

$$\begin{aligned} h_C &= (8 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (9 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-208,450 \text{ kJ/kmol}) \\ &= -5,116,090 \text{ kJ/kmol} \text{ octane} \end{aligned}$$

The LHV of the gaseous octane is then

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{5,116,090 \text{ kJ/kmol C}_8\text{H}_{18}}{114.231 \text{ kg/kmol C}_8\text{H}_{18}} = \mathbf{44,790 \text{ kJ/kg C}_8\text{H}_{18}}$$

The listed value for liquid octane from Table A-27 is 44,430 kJ/kg. Adding the enthalpy of vaporization of octane to this value (44,430+363=44,793), the lower heating value of gaseous octane becomes **44,793 kJ/kg** octane. This value is practically identical to the calculated value.

15-53 The higher and lower heating values of coal from Illinois are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, SO₂, and N₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, O₂, S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{67.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.617 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.31 \text{ kg}}{2 \text{ kg/kmol}} = 2.655 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{15.11 \text{ kg}}{32 \text{ kg/kmol}} = 0.4722 \text{ kmol}$$

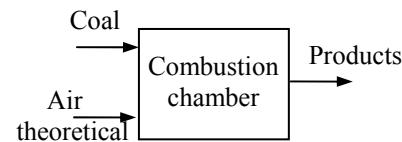

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1.44 \text{ kg}}{28 \text{ kg/kmol}} = 0.05143 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{2.36 \text{ kg}}{32 \text{ kg/kmol}} = 0.07375 \text{ kmol}$$

67.40% C
5.31% H ₂
15.11% O ₂
1.44% N ₂
2.36% S
8.38% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.617 + 2.655 + 0.4722 + 0.05143 + 0.07375 = 8.869 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{5.617 \text{ kmol}}{8.869 \text{ kmol}} = 0.6333$$

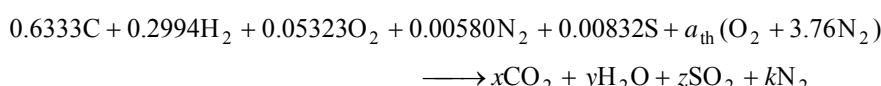

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.655 \text{ kmol}}{8.869 \text{ kmol}} = 0.2994$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.4722 \text{ kmol}}{8.869 \text{ kmol}} = 0.05323$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.05143 \text{ kmol}}{8.869 \text{ kmol}} = 0.00580$$

$$y_S = \frac{N_S}{N_m} = \frac{0.07375 \text{ kmol}}{8.869 \text{ kmol}} = 0.00832$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the species balances,

$$\text{C balance: } x = 0.6333$$

$$\text{H}_2 \text{ balance: } y = 0.2994$$

$$\text{S balance: } z = 0.00832$$

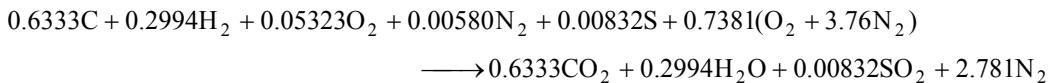

$$\text{O}_2 \text{ balance: }$$

$$0.05323 + a_{th} = x + 0.5y + z$$

$$a_{th} = 0.6333 + 0.5 \times 0.2994 + 0.00832 - 0.05323 = 0.7381$$

$$\text{N}_2 \text{ balance: } k = 0.00580 + 3.76a_{th} = 0.00580 + 3.76 \times 0.7381 = 2.781$$

Substituting,

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that C, S, H₂, N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (\bar{h}_{f,C}^\circ)_{\text{CO}_2} + (\bar{h}_{f,\text{H}_2\text{O}}^\circ)_{\text{H}_2\text{O}} + (\bar{h}_{f,\text{SO}_2}^\circ)_{\text{SO}_2}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$\begin{aligned} h_C &= (0.6333 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (0.2994 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad + (0.00832 \text{ kmol})(-297,100 \text{ kJ/kmol}) \\ &= -337,270 \text{ kJ/kmol coal} \end{aligned}$$

The apparent molecular weight of the coal is

$$\begin{aligned} M_m &= \frac{m_m}{N_m} = \frac{(0.6333 \times 12 + 0.2994 \times 2 + 0.05323 \times 32 + 0.00580 \times 28 + 0.00832 \times 32) \text{ kg}}{(0.6333 + 0.2994 + 0.05323 + 0.00580 + 0.00832) \text{ kmol}} \\ &= \frac{10.33 \text{ kg}}{1.000 \text{ kmol}} = 10.33 \text{ kg/kmol coal} \end{aligned}$$

The HHV of the coal is then

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{337,270 \text{ kJ/kmol coal}}{10.33 \text{ kg/kmol coal}} = \mathbf{32,650 \text{ kJ/kg coal}}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$\begin{aligned} h_C &= (0.6333 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (0.2994 \text{ kmol})(-241,820 \text{ kJ/kmol}) \\ &\quad + (0.00832 \text{ kmol})(-297,100 \text{ kJ/kmol}) \\ &= -324,090 \text{ kJ/kmol coal} \end{aligned}$$

The LHV of the coal is then

$$\text{LHV} = \frac{-h_C}{M_m} = \frac{324,090 \text{ kJ/kmol coal}}{10.33 \text{ kg/kmol coal}} = \mathbf{31,370 \text{ kJ/kg coal}}$$

First Law Analysis of Reacting Systems

15-54C In this case $\Delta U + W_b = \Delta H$, and the conservation of energy relation reduces to the form of the steady-flow energy relation.

15-55C The heat transfer will be the same for all cases. The excess oxygen and nitrogen enters and leaves the combustion chamber at the same state, and thus has no effect on the energy balance.

15-56C For case (b), which contains the maximum amount of nonreacting gases. This is because part of the chemical energy released in the combustion chamber is absorbed and transported out by the nonreacting gases.

15-57 Propane is burned with an air-fuel ratio of 25. The heat transfer per kilogram of fuel burned when the temperature of the products is such that liquid water just begins to form in the products is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The reactants are at 25°C and 1 atm. 6 The fuel is in vapor phase.

Properties The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The mass of air per kmol of fuel is

$$\begin{aligned}m_{\text{air}} &= (\text{AF})m_{\text{fuel}} \\&= (25 \text{ kg air/kg fuel})(1 \times 44 \text{ kg/kmol fuel}) = 1100 \text{ kg air/kmol fuel}\end{aligned}$$

The mole number of air per kmol of fuel is then

$$N_{\text{air}} = \frac{m_{\text{air}}}{M_{\text{air}}} = \frac{1100 \text{ kg air/kmol fuel}}{29 \text{ kg air/kmol air}} = 37.93 \text{ kmol air/kmol fuel}$$

The combustion equation can be written as

The coefficient for O₂ is obtained from O₂ balance:

$$(37.93/4.76) = 3 + 2 + x \longrightarrow x = 2.968$$

Substituting, C₃H₈ + 7.968(O₂ + 3.76N₂) → 3CO₂ + 4H₂O + 2.968O₂ + 29.96N₂

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{4 \text{ kmol}}{(3 + 4 + 2.968 + 29.96) \text{ kmol}} = \frac{4 \text{ kmol}}{39.93 \text{ kmol}} = 0.1002$$

The partial pressure of water vapor at 1 atm total pressure is

$$P_v = y_v P = (0.1002)(101.325 \text{ kPa}) = 10.15 \text{ kPa}$$

When this mixture is at the dew-point temperature, the water vapor pressure is the same as the saturation pressure. Then,

$$T_{\text{dp}} = T_{\text{sat@10.15 kPa}} = 46.1^\circ\text{C} = 319.1\text{K} \cong 320\text{K}$$

We obtain properties at 320 K (instead of 319.1 K) to avoid iterations in the ideal gas tables. The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\bar{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° , kJ/kmol	$\bar{h}_{298\text{K}}$, kJ/kmol	$\bar{h}_{320\text{K}}$, kJ/kmol
C ₃ H ₈	-103,850	---	---
O ₂	0	8682	9325
N ₂	0	8669	9306
H ₂ O (g)	-241,820	9904	10,639
CO ₂	-393,520	9364	10,186

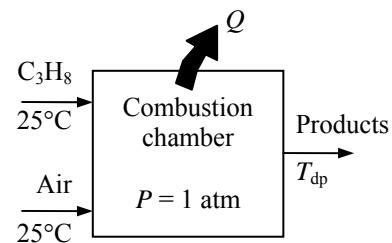

Substituting,

$$\begin{aligned}-\bar{Q}_{\text{out}} &= (3)(-393,520 + 10,186 - 9364) + (4)(-241,820 + 10,639 - 9904) + (2.968)(0 + 9325 - 8682) \\&\quad + (29.96)(0 + 9306 - 8669) - (1)(-103,850) - 0 \\&= -2,017,590 \text{ kJ/kmol C}_3\text{H}_8\end{aligned}$$

$$\text{or } \bar{Q}_{\text{out}} = 2,017,590 \text{ kJ/kmol C}_3\text{H}_8$$

Then the heat transfer per kg of fuel is

$$\bar{Q}_{\text{out}} = \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{2,017,590 \text{ kJ/kmol fuel}}{44 \text{ kg/kmol}} = 45,850 \text{ kJ/kg C}_3\text{H}_8$$

15-58 n-Octane is burned with 100 percent excess air. The heat transfer per kilogram of fuel burned for a product temperature of 257°C is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The fuel is in vapor phase.

Properties The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction for stoichiometric air is

The combustion equation with 100% excess air is

The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\bar{Q}_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	\bar{h}_{298K} kJ/kmol	\bar{h}_{530K} kJ/kmol
C ₈ H ₁₈ (g)	-208,450	---	---
O ₂	0	8682	15,708
N ₂	0	8669	15,469
H ₂ O (g)	-241,820	9904	17,889
CO ₂	-393,520	9364	19,029

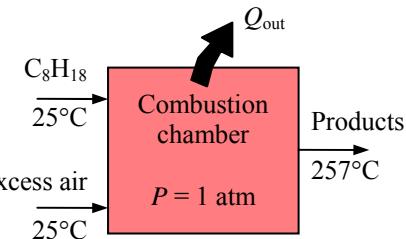

Substituting,

$$\begin{aligned} -\bar{Q}_{out} &= (8)(-393,520 + 19,029 - 9364) + (9)(-241,820 + 17,889 - 9904) + (12.5)(0 + 15,708 - 8682) \\ &\quad + (94)(0 + 15,469 - 8669) - (1)(-208,450) - 0 - 0 \\ &= -4,239,880 \text{ kJ/kmol C}_8\text{H}_{18} \end{aligned}$$

or $\bar{Q}_{out} = 4,239,880 \text{ kJ/kmol C}_8\text{H}_{18}$

Then the heat transfer per kg of fuel is

$$\bar{Q}_{out} = \frac{\bar{Q}_{out}}{M_{fuel}} = \frac{4,239,880 \text{ kJ/kmol fuel}}{114 \text{ kg/kmol}} = \mathbf{37,200 \text{ kJ/kg C}_8\text{H}_{18}}$$

15-59 Propane is burned with 50 percent excess air during a steady-flow combustion process. The rate of heat transfer in the combustion chamber is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Properties The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation can be written as

The stoichiometric coefficient is obtained from O₂ balance:

$$1.5a_{\text{th}} = 3 + 2 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Substituting,

The specific volume of the air entering the system is

$$\nu_{\text{air}} = \frac{R_{\text{air}}T}{P} = \frac{(0.287 \text{ kJ/kmol} \cdot \text{K})(773 \text{ K})}{101.3 \text{ kPa}} = 2.190 \text{ m}^3/\text{kg}$$

and the mass flow rate of this air is

$$\dot{m}_{\text{air}} = \frac{\dot{V}_{\text{air}}}{\nu_{\text{air}}} = \frac{1 \text{ m}^3/\text{s}}{2.190 \text{ m}^3/\text{kg}} = 0.4566 \text{ kg/s}$$

The air-fuel ratio for this combustion process is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(7.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = 23.53 \text{ kg air/kg fuel}$$

The mass flow rate of fuel is

$$\dot{m}_{\text{fuel}} = \frac{\dot{m}_{\text{air}}}{\text{AF}} = \frac{0.4566 \text{ kg/s}}{23.53} = 0.01941 \text{ kg/s}$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{773 \text{ K}}$ kJ/kmol	$\bar{h}_{1773 \text{ K}}$ kJ/kmol
C ₃ H ₈	-103,850	---	---	---
O ₂	0	8682	23,614	59,364
N ₂	0	8669	22,866	56,689
H ₂ O (g)	-241,820	9904	---	71,177
CO ₂	-393,520	9364	---	87,195

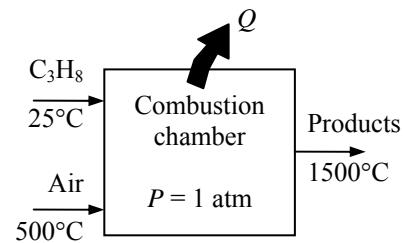

Substituting,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (3)(-393,520 + 87,195 - 9364) + (4)(-241,820 + 71,177 - 9904) + (2.5)(0 + 59,364 - 8682) \\ &\quad + (28.2)(0 + 56,689 - 8669) - (1)(-103,850 + h_{298} - h_{298}) - (7.5)(0 + 23,614 - 8682) \\ &\quad - (28.2)(0 + 22,866 - 8669) \\ &= -596,881 \text{ kJ/kmol C}_3\text{H}_8 \end{aligned}$$

or $\dot{Q}_{\text{out}} = 596,881 \text{ kJ/kmol C}_3\text{H}_8$

Then the rate of heat transfer for a mass flow rate of 0.01941 kg/s for the propane becomes

$$\dot{Q}_{\text{out}} = \dot{N}\dot{Q}_{\text{out}} = \left(\frac{\dot{m}}{M} \right) \dot{Q}_{\text{out}} = \left(\frac{0.01941 \text{ kg/s}}{44 \text{ kg/kmol}} \right) (596,881 \text{ kJ/kmol}) = 263.3 \text{ kW}$$

15-60 Methane is burned completely during a steady-flow combustion process. The heat transfer from the combustion chamber is to be determined for two cases.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

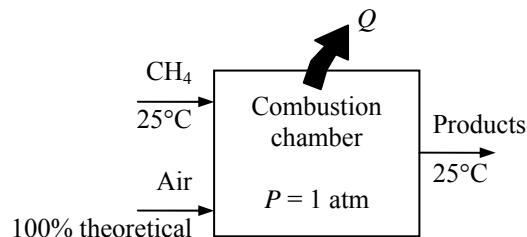

Analysis The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only H₂O, CO₂ and N₂, but no free O₂. Considering 1 kmol of fuel, the theoretical combustion equation can be written as

where a_{th} is determined from the O₂ balance,

$$a_{\text{th}} = 1 + 1 = 2$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ$$

since both the reactants and the products are at 25°C and both the air and the combustion gases can be treated as ideal gases. From the tables,

Substance	\bar{h}_f° kJ/kmol
CH ₄	-74,850
O ₂	0
N ₂	0
H ₂ O (l)	-285,830
CO ₂	-393,520

Thus,

$$-Q_{\text{out}} = (1)(-393,520) + (2)(-285,830) + 0 - (1)(-74,850) - 0 - 0 = -890,330 \text{ kJ / kmol CH}_4$$

or

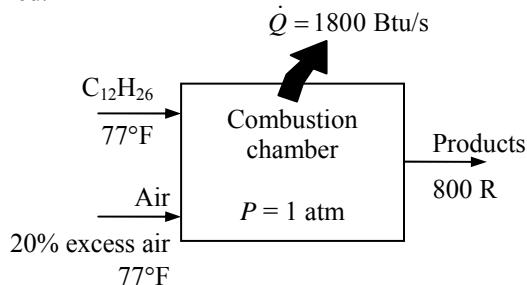

$$Q_{\text{out}} = 890,330 \text{ kJ / kmol CH}_4$$

If combustion is achieved with 100% excess air, the answer would still be the same since it would enter and leave at 25°C, and absorb no energy.

15-61E Diesel fuel is burned with 20 percent excess air during a steady-flow combustion process. The required mass flow rate of the diesel fuel for a specified heat transfer rate is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol of C₁₂H₂₆, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$1.2a_{\text{th}} = 12 + 6.5 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 18.5$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 77°F. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{ R}}$ Btu/lbmol	$\bar{h}_{800\text{ R}}$ Btu/lbmol
C ₁₂ H ₂₆	-125,190	---	---
O ₂	0	3725.1	5602.0
N ₂	0	3729.5	5564.4
H ₂ O (g)	-104,040	4258.0	6396.9
CO ₂	-169,300	4027.5	6552.9

Thus,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (12)(-169,300 + 6552.9 - 4027.5) + (13)(-104,040 + 6396.9 - 4258) \\ &\quad + (3.7)(0 + 5602.0 - 3725.1) + (83.47)(0 + 5564.4 - 3729.5) - (1)(-125,190) - 0 - 0 \\ &= -3,040,716 \text{ Btu/lbmol C}_{12}\text{H}_{26} \end{aligned}$$

$$\text{or } \dot{Q}_{\text{out}} = 3,040,716 \text{ Btu/lbmol C}_{12}\text{H}_{26}$$

Then the required mass flow rate of fuel for a heat transfer rate of 1800 Btu/s becomes

$$\dot{m} = \dot{N}M = \left(\frac{\dot{Q}}{Q} \right) M = \left(\frac{1800 \text{ Btu/s}}{3,040,716 \text{ Btu/lbmol}} \right) (170 \text{ lbm/lbmol}) = \mathbf{0.1006 \text{ lbm/s}}$$

15-62 A certain coal is burned steadily with 40% excess air. The heat transfer for a given product temperature is to be determined.

Assumptions **1** Combustion is complete. **2** The combustion products contain CO₂, CO, H₂O, SO₂, and N₂. **3** Combustion gases are ideal gases.

Properties The molar masses of C, H₂, N₂, O₂, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{39.25 \text{ kg}}{12 \text{ kg/kmol}} = 3.271 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{6.93 \text{ kg}}{2 \text{ kg/kmol}} = 3.465 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{41.11 \text{ kg}}{32 \text{ kg/kmol}} = 1.285 \text{ kmol}$$

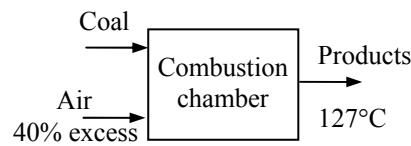

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{0.72 \text{ kg}}{28 \text{ kg/kmol}} = 0.0257 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.79 \text{ kg}}{32 \text{ kg/kmol}} = 0.0247 \text{ kmol}$$

39.25% C
6.93% H ₂
41.11% O ₂
0.72% N ₂
0.79% S
11.20% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 3.271 + 3.465 + 1.285 + 0.0257 + 0.0247 = 8.071 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{3.271 \text{ kmol}}{8.071 \text{ kmol}} = 0.4052$$

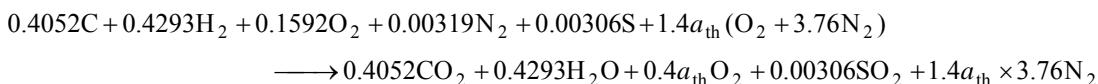

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{3.465 \text{ kmol}}{8.071 \text{ kmol}} = 0.4293$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{1.285 \text{ kmol}}{8.071 \text{ kmol}} = 0.1592$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.0257 \text{ kmol}}{8.071 \text{ kmol}} = 0.00319$$

$$y_S = \frac{N_S}{N_m} = \frac{0.0247 \text{ kmol}}{8.071 \text{ kmol}} = 0.00306$$

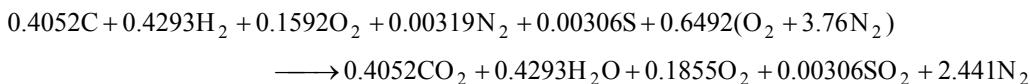

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the O₂ mass balance,

$$0.1592 + 1.4a_{th} = 0.4052 + 0.5 \times 0.4293 + 0.4a_{th} + 0.00306 \longrightarrow a_{th} = 0.4637$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{400\text{ K}}$ kJ/kmol
O ₂	0	8682	11,711
N ₂	0	8669	11,640
H ₂ O (g)	-241,820	9904	13,356
CO ₂	-393,520	9364	13,372
SO ₂	-297,100	-	-

The enthalpy change of sulfur dioxide between the standard temperature and the product temperature using constant specific heat assumption is

$$\Delta \bar{h}_{\text{SO}_2} = c_p \Delta T = (41.7 \text{ kJ/kmol}\cdot\text{K})(127 - 25)\text{K} = 4253 \text{ kJ/kmol}$$

Substituting into the energy balance relation,

$$\begin{aligned} -\bar{Q}_{\text{out}} &= (0.4052)(-393,520 + 13,372 - 9364) + (0.4293)(-241,820 + 13,356 - 9904) \\ &\quad + (0.1855)(0 + 11,711 - 8682) + (2.441)(0 + 11,640 - 8669) + (0.00306)(-297,100 + 4253) - 0 \\ &= -253,244 \text{ kJ/kmol C}_8\text{H}_{18} \end{aligned}$$

or $\bar{Q}_{\text{out}} = 253,244 \text{ kJ/kmol fuel}$

Then the heat transfer per kg of fuel is

$$\begin{aligned} Q_{\text{out}} &= \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{253,244 \text{ kJ/kmol fuel}}{(0.4052 \times 12 + 0.4293 \times 2 + 0.1592 \times 32 + 0.00319 \times 28 + 0.00306 \times 32) \text{ kg/kmol}} \\ &= \frac{253,244 \text{ kJ/kmol fuel}}{11.00 \text{ kg/kmol}} \\ &= \mathbf{23,020 \text{ kJ/kg coal}} \end{aligned}$$

15-63 Octane gas is burned with 30 percent excess air during a steady-flow combustion process. The heat transfer per unit mass of octane is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Properties The molar mass of C₈H₁₈ is 114 kg/kmol (Table A-1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. The moisture in the air does not react with anything; it simply shows up as additional H₂O in the products.

Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of C₈H₁₈, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } 1.8a_{\text{th}} = 8 + 4.5 + 0.8a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Thus,

Therefore, $22.5 \times 4.76 = 107.1$ kmol of dry air will be used per kmol of the fuel. The partial pressure of the water vapor present in the incoming air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@25^\circ\text{C}} = (0.40)(3.1698 \text{ kPa}) = 1.268 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture that accompanies 107.1 kmol of incoming dry air is determined to be

$$N_{v,\text{in}} = \left(\frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left(\frac{1.268 \text{ kPa}}{101.325 \text{ kPa}} \right) (107.1 + N_{v,\text{in}}) \longrightarrow N_{v,\text{in}} = 1.36 \text{ kmol}$$

The balanced combustion equation is obtained by adding 1.36 kmol of H₂O to both sides of the equation,

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 25°C. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

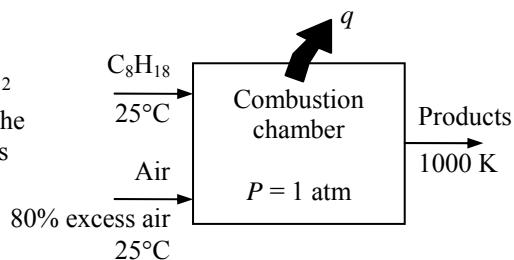

Substance	\bar{h}_f° , kJ/kmol	$\bar{h}_{298\text{ K}}$, kJ/kmol	$\bar{h}_{1000\text{ K}}$, kJ/kmol
C ₈ H ₁₈ (g)	-208,450	---	---
O ₂	0	8682	31,389
N ₂	0	8669	30,129
H ₂ O(g)	-241,820	9904	35,882
CO ₂	-393,520	9364	42,769

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (8)(-393,520 + 42,769 - 9364) + (10.36)(-241,820 + 35,882 - 9904) \\ &\quad + (10)(0 + 31,389 - 8682) + (84.6)(0 + 30,129 - 8669) \\ &\quad - (1)(-208,450) - (1.36)(-241,820) - 0 - 0 \\ &= -2,537,130 \text{ kJ/kmol C}_8\text{H}_{18} \end{aligned}$$

Thus 2,537,130 kJ of heat is transferred from the combustion chamber for each kmol (114 kg) of C₈H₁₈. Then the heat transfer per kg of C₈H₁₈ becomes

$$q = \frac{Q_{\text{out}}}{M} = \frac{2,537,130 \text{ kJ}}{114\text{kg}} = 22,260 \text{ kJ/kg C}_8\text{H}_{18}$$

15-64 Problem 15-63 is reconsidered. The effect of the amount of excess air on the heat transfer for the combustion process is to be investigated.

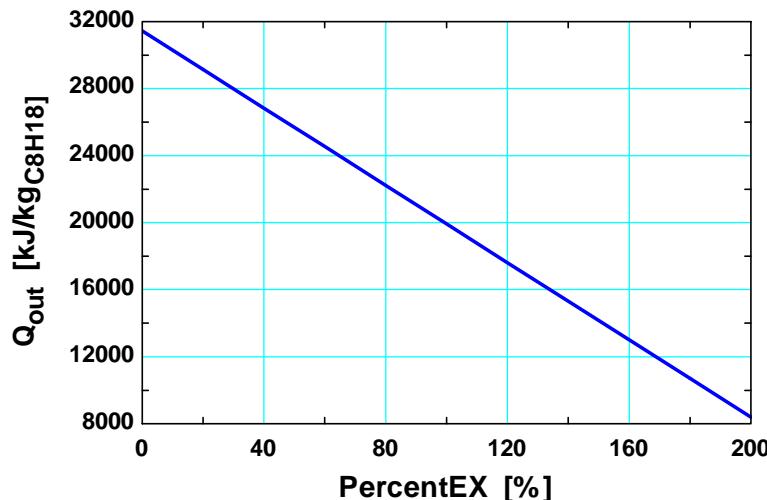

Analysis The problem is solved using EES, and the solution is given below.

15-65 Propane gas is burned with 100% excess air. The combustion is incomplete. The balanced chemical reaction is to be written, and the dew-point temperature of the products and the heat transfer from the combustion chamber are to be determined.

Assumptions 1 Combustion is incomplete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O₂ balance:

$$a_{\text{th}} = 3 + 2 = 5$$

Substituting,

The reaction with 100% excess air and incomplete combustion can be written as

The coefficient for O₂ is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 10 = 0.9 \times 3 + 0.05 \times 3 + 2 + x \longrightarrow x = 5.15$$

Substituting,

(b) The partial pressure of water vapor is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{4}{2.7 + 0.3 + 4 + 5.15 + 37.6} (100 \text{ kPa}) = \frac{4 \text{ kmol}}{49.75 \text{ kmol}} (100 \text{ kPa}) = 8.040 \text{ kPa}$$

The dew point temperature of the product gases is the saturation temperature of water at this pressure:

$$T_{dp} = T_{\text{sat}@8.04 \text{ kPa}} = 41.5^\circ\text{C} \quad (\text{Table A-5})$$

(c) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Both the reactants and products are at 25 °C. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. Also, since the temperature of products (25 °C) is lower than the dew-point temperature, some water vapor will condense. Noting from Table A-5 that $P_{\text{sat}@25^\circ\text{C}} = 3.17 \text{ kPa}$, the molar amount of water that remain as vapor is determined from

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} \longrightarrow 3.17 \text{ kPa} = \frac{N_{\text{H}_2\text{O,vapor}}}{N_{\text{H}_2\text{O,vapor}} + 2.7 + 0.3 + 5.15 + 37.6} (100 \text{ kPa}) \longrightarrow N_{\text{H}_2\text{O,vapor}} = 1.5 \text{ kmol}$$

Thus, $N_{\text{H}_2\text{O,liquid}} = 4 - 1.5 = 2.5 \text{ kmol}$

Then, using the values given in the table,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (2.7)(-393,520) + (0.3)(-110,530) + (1.5)(-241,820) + (2.5)(-285,830) - (1)(-103,850) \\ &= -2,069,120 \text{ kJ/kmol C}_3\text{H}_8 \end{aligned}$$

or $\dot{Q}_{\text{out}} = 2,069,120 \text{ kJ/kmol C}_3\text{H}_8$

Then the heat transfer for a 100 kmol fuel becomes

$$\dot{Q}_{\text{out}} = N \dot{Q}_{\text{out}} = \left(\frac{\dot{m}}{N} \right) \dot{Q}_{\text{out}} = (100 \text{ kmol fuel})(2,069,120 \text{ kJ/kmol fuel}) = 2.069 \times 10^8 \text{ kJ}$$

15-66 A mixture of propane and methane is burned with theoretical air. The balanced chemical reaction is to be written, and the amount of water vapor condensed and the required air flow rate for a given heat transfer rate are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

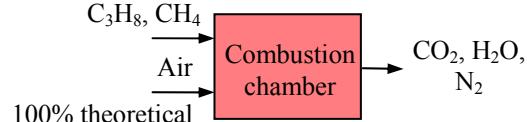

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O₂ balance:

$$a_{\text{th}} = 1.8 + 1.4 = 3.2$$

Substituting,

(b) The partial pressure of water vapor is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{2.8}{1.8 + 2.8 + 12.032} (100 \text{kPa}) = \frac{2.8 \text{ kmol}}{16.632 \text{ kmol}} (100 \text{kPa}) = 16.84 \text{kPa}$$

The dew point temperature of the product gases is the saturation temperature of water at this pressure:

$$T_{dp} = T_{\text{sat}@16.84 \text{kPa}} = 56.2^\circ\text{C} \quad (\text{Table A-5})$$

Since the temperature of the product gases are at 398 K (125°C), there will be no condensation of water vapor.

(c) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

The products are at 125°C, and the enthalpy of products can be expressed as

$$(\bar{h} - \bar{h}^\circ) = \bar{c}_p \Delta T$$

where $\Delta T = 125 - 25 = 100^\circ\text{C} = 100 \text{ K}$. Then, using the values given in the table,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (1.8)(-393,520 + 41.16 \times 100) + (2.8)(-241,820 + 34.28 \times 100) + (12.032)(0 + 29.27 \times 100) \\ &\quad - (0.4)(-103,850) - (0.6)(-74,850) \\ &= -1,246,760 \text{ kJ/kmol fuel} \end{aligned}$$

or $\dot{Q}_{\text{out}} = 1,246,760 \text{ kJ/kmol fuel}$

For a heat transfer rate of 97,000 kJ/h, the molar flow rate of fuel is

$$\dot{N}_{\text{fuel}} = \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{out}}} = \frac{97,000 \text{ kJ/h}}{1,246,760 \text{ kJ/kmol fuel}} = 0.07780 \text{ kmol fuel/h}$$

The molar mass of the fuel mixture is

$$M_{\text{fuel}} = 0.4 \times 44 + 0.6 \times 16 = 27.2 \text{ kg/kmol}$$

The mass flow rate of fuel is

$$\dot{m}_{\text{fuel}} = \dot{N}_{\text{fuel}} M_{\text{fuel}} = (0.07780 \text{ kmol/h})(27.2 \text{ kg/kmol}) = 2.116 \text{ kg/h}$$

The air-fuel ratio is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(3.2 \times 4.76 \times 29) \text{ kg}}{(0.4 \times 44 + 0.6 \times 16) \text{ kg}} = 16.24 \text{ kg air/kg fuel}$$

The mass flow rate of air is then

$$\dot{m}_{\text{air}} = \dot{m}_{\text{fuel}} \text{AF} = (2.116 \text{ kg/h})16.24 = \mathbf{34.4 \text{ kg/h}}$$

15-67 A mixture of ethanol and octane is burned with 10% excess air. The combustion is incomplete. The balanced chemical reaction is to be written, and the dew-point temperature of the products, the heat transfer for the process, and the relative humidity of atmospheric air for specified conditions are to be determined.

Assumptions 1 Combustion is incomplete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

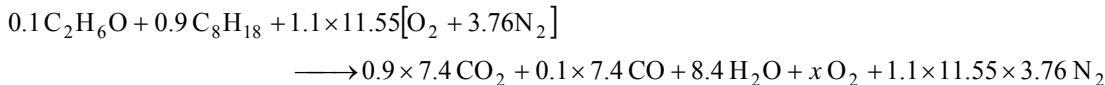

The stoichiometric coefficient a_{th} is determined from an O₂ balance:

$$0.1/2 + a_{\text{th}} = 7.4 + 8.4/2 \longrightarrow a_{\text{th}} = 11.55$$

Substituting,

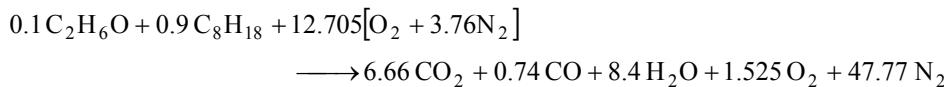

The reaction with 10% excess air and incomplete combustion can be written as

The coefficient for O₂ is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 0.5 \times 0.1 + 1.1 \times 11.55 = 0.9 \times 7.4 + 0.5 \times (0.1 \times 7.4) + 0.5 \times 8.4 + x \longrightarrow x = 1.525$$

Substituting,

(b) The partial pressure of water vapor is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{8.4}{6.66 + 0.74 + 8.4 + 1.525 + 47.77} (100 \text{ kPa}) = \frac{8.4 \text{ kmol}}{65.10 \text{ kmol}} (100 \text{ kPa}) = 12.9 \text{ kPa}$$

The dew point temperature of the product gases is the saturation temperature of water at this pressure:

$$T_{dp} = T_{\text{sat}@12.9 \text{ kPa}} = 50.5^\circ\text{C} \quad (\text{Table A-5})$$

(c) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

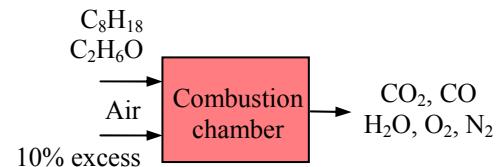

Both the reactants and products are at 25 °C. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. Then, using the values given in the table,

$$\begin{aligned} -Q_{\text{out}} &= (6.66)(-393,520) + (0.74)(-110,530) + (8.4)(-241,820) - (0.1)(-235,310) - (0.9)(-208,450) \\ &= -4,522,790 \text{ kJ/kmol fuel} \end{aligned}$$

or $Q_{\text{out}} = 4,522,790 \text{ kJ/kmol fuel}$

The molar mass of the fuel is

$$M = 0.1 \times 46 + 0.9 \times 114 = 107.2 \text{ kg/kmol}$$

Then the heat transfer for a 2.5 kg of fuel becomes

$$Q_{\text{out}} = NQ_{\text{out}} = \left(\frac{m}{M} \right) Q_{\text{out}} = \frac{2.5 \text{ kg}}{107.2 \text{ kg/kmol}} (4,522,790 \text{ kJ/mol}) = \mathbf{105,480 \text{ kJ}}$$

(d) For 9.57 kmol of water vapor in the products, the air must carry $9.57 - 8.4 = 1.17$ kmol of water vapor in the atmospheric air. The partial pressure of this water vapor in the atmospheric air is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{1.17}{12.705 \times 4.76 + 1.17} (100 \text{ kPa}) = \frac{1.17 \text{ kmol}}{61.65 \text{ kmol}} (100 \text{ kPa}) = 1.8979 \text{ kPa}$$

The saturation pressure of water at 25°C is 3.17 kPa (Table A-4). The relative humidity of water vapor in the atmospheric air is then

$$\phi = \frac{P_v}{P_{\text{total}}} = \frac{1.8979 \text{ kPa}}{3.17 \text{ kPa}} = 0.599 = \mathbf{59.9\%}$$

15-68 A mixture of methane and oxygen contained in a tank is burned at constant volume. The final pressure in the tank and the heat transfer during this process are to be determined.

Assumptions 1 Air and combustion gases are ideal gases. 2 Combustion is complete.

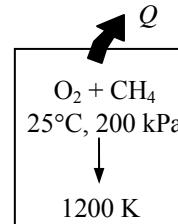

Properties The molar masses of CH₄ and O₂ are 16 kg/kmol and 32 kg/kmol, respectively (Table A-1).

Analysis (a) The combustion is assumed to be complete, and thus all the carbon in the methane burns to CO₂ and all of the hydrogen to H₂O. The number of moles of CH₄ and O₂ in the tank are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{0.12 \text{ kg}}{16 \text{ kg/kmol}} = 7.5 \times 10^{-3} \text{ kmol} = 7.5 \text{ mol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.6 \text{ kg}}{32 \text{ kg/kmol}} = 18.75 \times 10^{-3} \text{ kmol} = 18.75 \text{ mol}$$

Then the combustion equation can be written as

At 1200 K, water exists in the gas phase. Assuming both the reactants and the products to be ideal gases, the final pressure in the tank is determined to be

$$\left. \begin{array}{l} P_R V = N_R R_u T_R \\ P_P V = N_P R_u T_P \end{array} \right\} P_P = P_R \left(\frac{N_P}{N_R} \right) \left(\frac{T_P}{T_R} \right)$$

Substituting,

$$P_P = (200 \text{ kPa}) \left(\frac{26.25 \text{ mol}}{26.25 \text{ mol}} \right) \left(\frac{1200 \text{ K}}{298 \text{ K}} \right) = 805 \text{ kPa}$$

which is relatively low. Therefore, the ideal gas assumption utilized earlier is appropriate.

(b) The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1200 \text{ K}} - \bar{h}_{298 \text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{1200 \text{ K}}$ kJ/kmol
CH ₄	-74,850	---	---
O ₂	0	8682	38,447
H ₂ O (g)	-241,820	9904	44,380
CO ₂	-393,520	9364	53,848

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (7.5)(-393,520 + 53,848 - 9364 - 8.314 \times 1200) \\ &\quad + (15)(-241,820 + 44,380 - 9904 - 8.314 \times 1200) \\ &\quad + (3.75)(0 + 38,447 - 8682 - 8.314 \times 1200) \\ &\quad - (7.5)(-74,850 - 8.314 \times 298) - (18.75)(-8.314 \times 298) \\ &= -5,251,791 \text{ J} = -5252 \text{ kJ} \end{aligned}$$

Thus $Q_{\text{out}} = 5252 \text{ kJ}$ of heat is transferred from the combustion chamber as 120 g of CH₄ burned in this combustion chamber.

15-69 Problem 15-68 is reconsidered. The effect of the final temperature on the final pressure and the heat transfer for the combustion process is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

15-70E Methane is burned with stoichiometric amount of air in a rigid container. The heat rejected from the container is to be determined.

Assumptions 1 Air and combustion gases are ideal gases. 2 Combustion is complete.

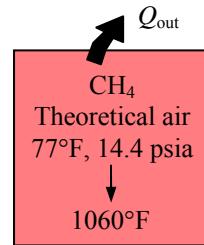

Properties The molar masses of CH₄ and air are 16 lbm/lbmol and 29 lbm/lbmol, respectively (Table A-1E).

Analysis The combustion equation for 1 lbmol of fuel is

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1520\text{R}} - \bar{h}_{537\text{R}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 77°F. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{R}}$ Btu/lbmol	$\bar{h}_{1520\text{R}}$ Btu/lbmol
CH ₄	-32,210	---	---
O ₂	0	3725.1	11,179.6
N ₂	0	3729.5	10,800.4
H ₂ O (g)	-104,040	4258.0	12,738.8
CO ₂	-169,300	4027.5	14,824.9

Thus,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (1)(-169,300 + 14,824.9 - 4027.5 - 1.9858 \times 1520) \\ &\quad + (2)(-104,040 + 12,738.8 - 4258.0 - 1.9858 \times 1520) \\ &\quad + (7.52)(0 + 10,800.4 - 3729.5 - 1.9858 \times 1520) \\ &\quad - (1)(-32,210 - 1.9858 \times 537) - (2)(-1.9858 \times 537) - (7.52)(-1.9858 \times 537) \\ &= -284,800 \text{ Btu/lbmol CH}_4 \end{aligned}$$

Thus

$$\dot{Q}_{\text{out}} = \mathbf{284,800 \text{ Btu/lbmol CH}_4}$$

15-71 A mixture of benzene gas and 30 percent excess air contained in a constant-volume tank is ignited. The heat transfer from the combustion chamber is to be determined.

Assumptions 1 Both the reactants and products are ideal gases. **2** Combustion is complete.

Analysis The theoretical combustion equation of C₆H₆ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$a_{\text{th}} = 6 + 1.5 = 7.5$$

Then the actual combustion equation with 30% excess air becomes

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$.

It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1000\text{ K}} - \bar{h}_{298\text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

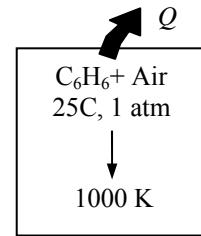

since the reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1000\text{ K}}$ kJ/kmol
C ₆ H ₆ (g)	82,930	---	---
O ₂	0	8682	31,389
N ₂	0	8669	30,129
H ₂ O (g)	-241,820	9904	35,882
CO	-110,530	8669	30,355
CO ₂	-393,520	9364	42,769

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (5.52)(-393,520 + 42,769 - 9364 - 8.314 \times 1000) \\ &\quad + (0.48)(-110,530 + 30,355 - 8669 - 8.314 \times 1000) \\ &\quad + (3)(-241,820 + 35,882 - 9904 - 8.314 \times 1000) \\ &\quad + (2.49)(0 + 31,389 - 8682 - 8.314 \times 1000) \\ &\quad + (36.66)(0 + 30,129 - 8669 - 8.314 \times 1000) \\ &\quad - (1)(82,930 - 8.314 \times 298) - (9.75)(4.76)(-8.314 \times 298) \\ &= -2,200,433 \text{ kJ} \end{aligned}$$

or $Q_{\text{out}} = 2,200,433 \text{ kJ}$

15-72E A mixture of benzene gas and 60 percent excess air contained in a constant-volume tank is ignited. The heat transfer from the combustion chamber is to be determined.

Assumptions 1 Both the reactants and products are ideal gases. **2** Combustion is complete.

Analysis The theoretical combustion equation of C₆H₆ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$a_{\text{th}} = 6 + 1.5 = 7.5$$

Then the actual combustion equation with 60% excess air becomes

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with W = 0. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$.

It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1800\text{R}} - \bar{h}_{537\text{R}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

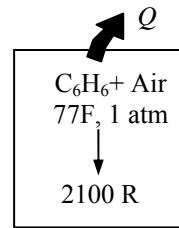

since the reactants are at the standard reference temperature of 77°F. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{R}}$ Btu/lbmol	$\bar{h}_{1800\text{R}}$ Btu/lbmol
C ₆ H ₆ (g)	35,680	---	---
O ₂	0	3725.1	16,011
N ₂	0	3729.5	15,334
H ₂ O (g)	-104,040	4258.0	18,467
CO	-47,540	3725.1	15,463
CO ₂	-169,300	4027.5	22,353

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (5.52)(-169,300 + 22,353 - 4027.5 - 1.986 \times 2100) \\ &\quad + (0.48)(-47,540 + 15,463 - 3725.1 - 1.986 \times 2100) \\ &\quad + (3)(-104,040 + 18,467 - 4258.0 - 1.986 \times 2100) \\ &\quad + (4.74)(0 + 16,011 - 3725.1 - 1.986 \times 2100) \\ &\quad + (45.12)(0 + 15,334 - 3729.5 - 1.986 \times 2100) \\ &\quad - (1)(35,680 - 1.986 \times 537) - (12)(4.76)(-1.986 \times 537) \\ &= -757,400 \text{ Btu} \end{aligned}$$

or $Q_{\text{out}} = 757,400 \text{ Btu}$

15-73 A high efficiency gas furnace burns gaseous propane C₃H₈ with 140 percent theoretical air. The volume flow rate of water condensed from the product gases is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 40% excess air (140% theoretical air) is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 40% excess air by using the factor 1.4a_{th} instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

Carbon balance: $B = 3$

Hydrogen balance: $2D = 8 \longrightarrow D = 4$

Oxygen balance: $2 \times 1.4a_{\text{th}} = 2B + D + 2E$

$$0.4a_{\text{th}} = E$$

Nitrogen balance: $1.4a_{\text{th}} \times 3.76 = F$

Solving the above equations, we find the coefficients ($E = 2$, $F = 26.32$, and $a_{\text{th}} = 5$) and write the balanced reaction equation as

The partial pressure of water in the saturated product mixture at the dew point is

$$P_{v,\text{prod}} = P_{\text{sat}@40^\circ\text{C}} = 7.3851 \text{ kPa}$$

The vapor mole fraction is

$$y_v = \frac{P_{v,\text{prod}}}{P_{\text{prod}}} = \frac{7.3851 \text{ kPa}}{100 \text{ kPa}} = 0.07385$$

The kmoles of water condensed is determined from

$$y_v = \frac{N_{\text{water}}}{N_{\text{total,product}}} \longrightarrow 0.07385 = \frac{4 - N_w}{3 + 4 - N_w + 2 + 26.32} \longrightarrow N_w = 1.503 \text{ kmol}$$

The steady-flow energy balance is expressed as

$$\dot{N}_{\text{fuel}} H_R = \dot{Q}_{\text{fuel}} + \dot{N}_{\text{fuel}} H_P$$

where $\dot{Q}_{\text{fuel}} = \frac{\dot{Q}_{\text{out}}}{\eta_{\text{furnace}}} = \frac{31,650 \text{ kJ/h}}{0.96} = 32,969 \text{ kJ/h}$

$$\begin{aligned} H_R &= \bar{h}_f^o_{\text{fuel}@25^\circ\text{C}} + 7\bar{h}_{\text{O}_2@25^\circ\text{C}} + 26.32\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= (-103,847 \text{ kJ/kmol}) + 7(0) + 26.32(0) = -103,847 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} H_P &= 3\bar{h}_{\text{CO}_2@25^\circ\text{C}} + 4\bar{h}_{\text{H}_2\text{O}@25^\circ\text{C}} + 2\bar{h}_{\text{O}_2@25^\circ\text{C}} + 26.32\bar{h}_{\text{N}_2@25^\circ\text{C}} + N_w(\bar{h}_f^o_{\text{H}_2\text{O(liq)}}) \\ &= 3(-393,520 \text{ kJ/kmol}) + 4(-241,820 \text{ kJ/kmol}) + 2(0) + 26.32(0) + 1.503(-285,830 \text{ kJ/kmol}) \\ &= -2.577 \times 10^6 \text{ kJ/kmol} \end{aligned}$$

Substituting into the energy balance equation,

$$\dot{N}_{\text{fuel}} H_R = \dot{Q}_{\text{fuel}} + \dot{N}_{\text{fuel}} H_P$$

$$\dot{N}_{\text{fuel}}(-103,847 \text{ kJ/kmol}) = 32,969 \text{ kJ/h} + \dot{N}_{\text{fuel}}(-2.577 \times 10^6 \text{ kJ/kmol}) \longrightarrow \dot{N}_{\text{fuel}} = 0.01333 \text{ kmol/h}$$

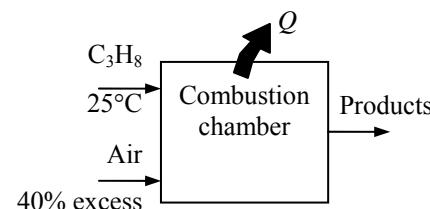

The molar and mass flow rates of the liquid water are

$$\dot{N}_w = N_w \dot{N}_{\text{fuel}} = (1.503 \text{ kmol/kmol fuel})(0.01333 \text{ kmol fuel/h}) = 0.02003 \text{ kmol/h}$$

$$\dot{m}_w = \dot{N}_w M_w = (0.02003 \text{ kmol/h})(18 \text{ kg/kmol}) = 0.3608 \text{ kg/h}$$

The volume flow rate of liquid water is

$$\dot{V}_w = (\nu_f @ 25^\circ\text{C}) \dot{m}_w = (0.001003 \text{ m}^3/\text{kg})(0.3608 \text{ kg/h}) = 0.0003619 \text{ m}^3/\text{h} = \mathbf{8.7 \text{ L/day}}$$

15-74 Wheat straw that is being considered as an alternative fuel is tested in a bomb calorimeter. The heating value of this straw is to be determined and compared to the higher heating value of propane.

Assumptions 1 Combustion is complete.

Analysis The heat released by the combustion is

$$Q = mc_v\Delta T = (100 \text{ kJ/K})(1.8 \text{ K}) = 180 \text{ kJ}$$

The heating value is then

$$\text{HV} = \frac{Q}{m} = \frac{180 \text{ kJ}}{0.010 \text{ kg}} = \mathbf{18,000 \text{ kJ/kg}}$$

From Table A-27, the higher heating value of propane is

$$\text{HHV} = \mathbf{50,330 \text{ kJ/kg}}$$

Adiabatic Flame Temperature

15-75C For the case of stoichiometric amount of pure oxygen since we have the same amount of chemical energy released but a smaller amount of mass to absorb it.

15-76C Under the conditions of complete combustion with stoichiometric amount of air.

15-77 Hydrogen is burned with 50 percent excess air during a steady-flow combustion process. The exit temperature of product gases is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$). Under steady-flow conditions the energy balance

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

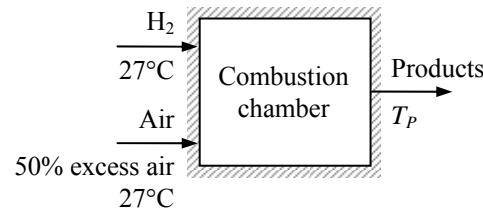

applied on the combustion chamber reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

The combustion equation of H_2 with 50% excess air is

From the tables,

Substance	\bar{h}_f°	$\bar{h}_{300\text{K}}$	$\bar{h}_{298\text{ K}}$
	kJ/kmol	kJ/kmol	kJ/kmol
H_2	0	8522	8468
O_2	0	8736	8682
N_2	0	8723	8669
H_2O (g)	-241,820	9966	9904

Thus,

$$(1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.25)(0 + \bar{h}_{\text{O}_2} - 8682) + (2.82)(0 + \bar{h}_{\text{N}_2} - 8669) \\ = (1)(0 + 8522 - 8468) + (0.75)(0 + 8736 - 8682) + (2.82)(0 + 8723 - 8669)$$

It yields

$$\bar{h}_{\text{H}_2\text{O}} + 0.25\bar{h}_{\text{O}_2} + 2.82\bar{h}_{\text{N}_2} = 278,590 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $278,590/(1 + 0.25 + 2.82) = 68,450 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2100 K for N_2 . Noting that the majority of the moles are N_2 , T_P will be close to 2100 K, but somewhat under it because of the higher specific heat of H_2O .

$$\text{At 2000 K: } \bar{h}_{\text{H}_2\text{O}} + 0.25\bar{h}_{\text{O}_2} + 2.82\bar{h}_{\text{N}_2} = (1)(82,593) + (0.25)(67,881) + (2.82)(64,810) \\ = 282,330 \text{ kJ (Higher than 278,590 kJ)}$$

$$\text{At 1960 K: } \bar{h}_{\text{H}_2\text{O}} + 0.25\bar{h}_{\text{O}_2} + 2.82\bar{h}_{\text{N}_2} = (1)(80,555) + (0.25)(66,374) + (2.82)(63,381) \\ = 275,880 \text{ kJ (Lower than 278,590 kJ)}$$

By interpolation, $T_P = 1977 \text{ K}$

Discussion The adiabatic flame temperature can be obtained by using EES without a trial and error approach. We found the temperature to be **1978 K** by EES. The results are practically identical.

15-78 Problem 15-77 is reconsidered. This problem is to be modified to include the fuels butane, ethane, methane, and propane as well as H₂; to include the effects of inlet air and fuel temperatures; and the percent theoretical air supplied.

Analysis The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel C_nH_m entering at T_fuel with Stoichiometric Air at T_air:

Reaction: C_xH_y + (y/4 + x) (Theo_air/100) (O₂ + 3.76 N₂)

T_prod is the adiabatic combustion temperature, assuming no dissociation.

Theo_air is the % theoretical air. "The initial guess value of T_prod = 450K."

15-79 Acetylene is burned with stoichiometric amount of oxygen. The adiabatic flame temperature is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

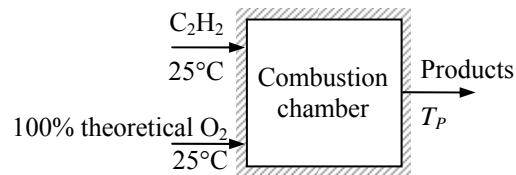

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

since all the reactants are at the standard reference temperature of 25°C. Then, for the stoichiometric oxygen

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
$\text{C}_2\text{H}_2(g)$	226,730	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$(2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) = (1)(226,730) + 0 + 0$$

It yields $2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{H}_2\text{O}} = 1,284,220 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,284,220/(2+1) = 428,074 \text{ kJ/kmol}$. The ideal gas tables do not list enthalpy values this high. Therefore, we cannot use the tables to estimate the adiabatic flame temperature. In Table A-2b, the highest available value of specific heat is $c_p = 1.234 \text{ kJ/kg}\cdot\text{K}$ for CO_2 at 1000 K. The specific heat of water vapor is $c_p = 1.8723 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a). Using these specific heat values,

$$(2)(-393,520 + \bar{c}_p \Delta T) + (1)(-241,820 + \bar{c}_p \Delta T) = (1)(226,730) + 0 + 0$$

where $\Delta T = (T_{\text{af}} - 25)^\circ\text{C}$. The specific heats on a molar base are

$$\bar{c}_{p,\text{CO}_2} = \bar{c}_p M = (1.234 \text{ kJ/kg}\cdot\text{K})(44 \text{ kg/kmol}) = 54.3 \text{ kJ/kmol}\cdot\text{K}$$

$$\bar{c}_{p,\text{H}_2\text{O}} = \bar{c}_p M = (1.8723 \text{ kJ/kg}\cdot\text{K})(18 \text{ kg/kmol}) = 33.7 \text{ kJ/kmol}\cdot\text{K}$$

Substituting,

$$(2)(-393,520 + 54.3 \Delta T) + (1)(-241,820 + 33.7 \Delta T) = 226,730$$

$$(2 \times 54.3) \Delta T + 33.7 \Delta T = 1,255,590$$

$$\Delta T = \frac{1,255,590 \text{ kJ/kmol}}{(2 \times 54.3 + 33.7) \text{ kJ/kmol}\cdot\text{K}} = 8824 \text{ K}$$

Then the adiabatic flame temperature is estimated as

$$T_{\text{af}} = \Delta T + 25 = 8824 + 25 = \mathbf{8849^\circ\text{C}}$$

15-80 Propane is burned with stoichiometric and 50 percent excess air. The adiabatic flame temperature is to be determined for both cases.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

since all the reactants are at the standard reference temperature of 25°C. Then, for the stoichiometric air

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

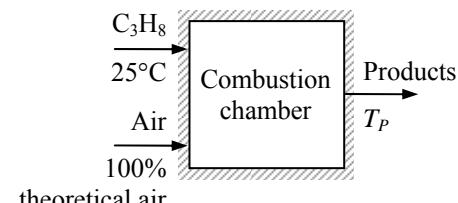

$$a_{th} = 3 + 2 = 5$$

Thus,

From the tables,

Substance	\bar{h}_f° kJ/kmol	\bar{h}_{298K} kJ/kmol
C ₃ H ₈ (g)	-103,850	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO ₂	-393,520	9364

Thus,

$$(3)(-393,520 + \bar{h}_{CO_2} - 9364) + (4)(-241,820 + \bar{h}_{H_2O} - 9904) + (18.8)(0 + \bar{h}_{N_2} - 8669) = (1)(-103,850) + 0 + 0$$

It yields $3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} = 2,274,680 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,274,680/(3 + 4 + 18.8) = 88,166 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2650 K for N₂. Noting that the majority of the moles are N₂, T_p will be close to 2650 K, but somewhat under it because of the higher specific heat of H₂O.

At 2500 K:

$$\begin{aligned} 3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} &= 3 \times 131,290 + 4 \times 108,868 + 18.8 \times 82,981 \\ &= 2,389,380 \text{ kJ} \text{ (Higher than } 2,274,680 \text{ kJ)} \end{aligned}$$

At 2450 K:

$$\begin{aligned} 3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} &= 3 \times 128,219 + 4 \times 106,183 + 18.8 \times 81,149 \\ &= 2,334,990 \text{ kJ} \text{ (Higher than } 2,274,680 \text{ kJ)} \end{aligned}$$

At 2400 K:

$$\begin{aligned} 3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} &= 3 \times 125,152 + 4 \times 103,508 + 18.8 \times 79,320 \\ &= 2,280,704 \text{ kJ} \text{ (Higher than } 2,274,680 \text{ kJ)} \end{aligned}$$

At 2350 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= 3 \times 122,091 + 4 \times 100,846 + 18.8 \times 77,496 \\ &= 2,226,580 \text{ kJ (Lower than } 2,274,680 \text{ kJ)} \end{aligned}$$

By interpolation of the two results,

$$T_p = \mathbf{2394 \text{ K} = 2121^\circ\text{C}}$$

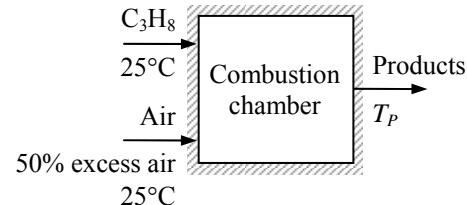

When propane is burned with 50% excess air, the reaction equation may be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.5a_{\text{th}} = 3 + 2 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Thus,

Using the values in the table,

$$\begin{aligned} (3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (2.5)(0 + \bar{h}_{\text{O}_2} - 8682) \\ + (28.2)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850) + 0 + 0 \end{aligned}$$

It yields $3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 2.5\bar{h}_{\text{O}_2} + 28.2\bar{h}_{\text{N}_2} = 2,377,870 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,377,870/(3+4+2.5+28.2) = 63,073 \text{ kJ/kmol}$. This enthalpy value corresponds to about 1960 K for N_2 . Noting that the majority of the moles are N_2 , T_p will be close to 1960 K, but somewhat under it because of the higher specific heat of H_2O .

At 1800 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 2.5\bar{h}_{\text{O}_2} + 28.2\bar{h}_{\text{N}_2} &= 3 \times 88,806 + 4 \times 72,513 + 2.5 \times 60,371 + 28.2 \times 57,651 \\ &= 2,333,160 \text{ kJ (Lower than } 2,377,870 \text{ kJ)} \end{aligned}$$

At 1840 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 2.5\bar{h}_{\text{O}_2} + 28.2\bar{h}_{\text{N}_2} &= 3 \times 91,196 + 4 \times 74,506 + 2.5 \times 61,866 + 28.2 \times 59,075 \\ &= 2,392,190 \text{ kJ (Higher than } 2,377,870 \text{ kJ)} \end{aligned}$$

By interpolation,

$$T_p = \mathbf{1830 \text{ K} = 1557^\circ\text{C}}$$

15-81 Octane is burned with 40 percent excess air adiabatically during a steady-flow combustion process. The exit temperature of product gases is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

since all the reactants are at the standard reference temperature of 25°C. Then,

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$1.4a_{th} = 8 + 4.5 + 0.4a_{th} \longrightarrow a_{th} = 12.5$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	\bar{h}_{298K} kJ/kmol	\bar{h}_{580K} kJ/kmol
C ₈ H ₁₈ (l)	-249,950	---	---
O ₂	0	8682	17,290
N ₂	0	8669	16,962
H ₂ O (g)	-241,820	9904	---
CO ₂	-393,520	9364	---

Thus,

$$(8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) + (5)(0 + \bar{h}_{O_2} - 8682) + (65.8)(0 + \bar{h}_{N_2} - 8669) = (1)(-249,950) + (17.5)(0 + 17,290 - 8682) + (65.8)(16,962 - 8669)$$

It yields $8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 5\bar{h}_{O_2} + 65.8\bar{h}_{N_2} = 6,548,788 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $6,548,788/(8 + 9 + 5 + 65.8) = 74,588 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2250 K for N₂. Noting that the majority of the moles are N₂, T_p will be close to 2250 K, but somewhat under it because of the higher specific heat of H₂O.

At 2100 K:

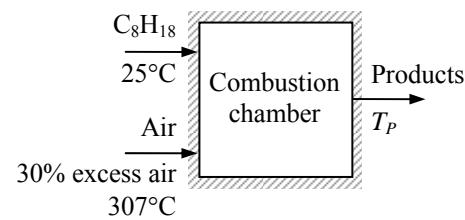

$$8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 5\bar{h}_{O_2} + 65.8\bar{h}_{N_2} = (8)(106,864) + (9)(87,735) + (5)(71,668) + (65.8)(68,417) = 6,504,706 \text{ kJ} \quad (\text{Lower than } 6,548,788 \text{ kJ})$$

At 2150 K:

$$8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 5\bar{h}_{O_2} + 65.8\bar{h}_{N_2} = (8)(109,898) + (9)(90,330) + (5)(73,573) + (65.8)(70,226) = 6,680,890 \text{ kJ} \quad (\text{Higher than } 6,548,788 \text{ kJ})$$

By interpolation,

$$T_p = 2113 \text{ K} = 1840^\circ\text{C}$$

15-82 A certain coal is burned with 100 percent excess air adiabatically during a steady-flow combustion process. The temperature of product gases is to be determined for complete combustion and incomplete combustion cases.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Properties The molar masses of C, H₂, N₂, O₂, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{84.36 \text{ kg}}{12 \text{ kg/kmol}} = 7.03 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{1.89 \text{ kg}}{2 \text{ kg/kmol}} = 0.945 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{4.40 \text{ kg}}{32 \text{ kg/kmol}} = 0.1375 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{0.63 \text{ kg}}{28 \text{ kg/kmol}} = 0.0225 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.89 \text{ kg}}{32 \text{ kg/kmol}} = 0.0278 \text{ kmol}$$

84.36% C
1.89% H ₂
4.40% O ₂
0.63% N ₂
0.89% S
7.83% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 7.03 + 0.945 + 0.1375 + 0.0225 + 0.0278 = 8.163 \text{ kmol}$$

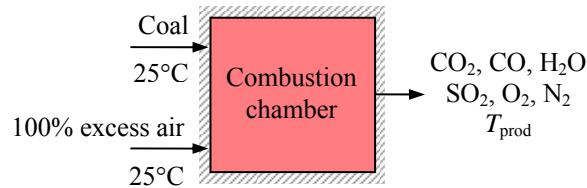

$$y_C = \frac{N_C}{N_m} = \frac{7.03 \text{ kmol}}{8.163 \text{ kmol}} = 0.8611$$

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{0.945 \text{ kmol}}{8.163 \text{ kmol}} = 0.1158$$

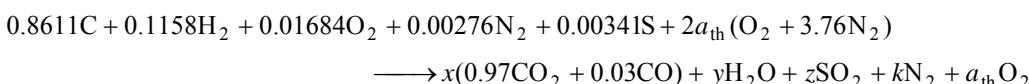

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.1375 \text{ kmol}}{8.163 \text{ kmol}} = 0.01684$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.0225 \text{ kmol}}{8.163 \text{ kmol}} = 0.00276$$

$$y_S = \frac{N_S}{N_m} = \frac{0.0278 \text{ kmol}}{8.163 \text{ kmol}} = 0.003407$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the species balances,

$$\text{C balance: } x = 0.8611$$

$$\text{H}_2 \text{ balance: } y = 0.1158$$

$$\text{S balance: } z = 0.00341$$

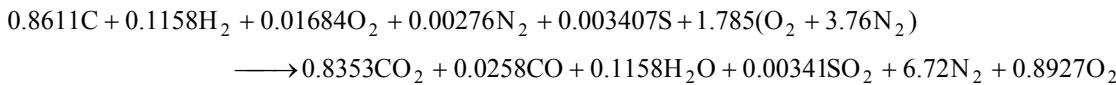

$$\text{O}_2 \text{ balance: }$$

$$0.01684 + 2a_{th} = 0.97x + 0.015y + 0.5z + a_{th}$$

$$a_{th} = (0.97)(0.8611) + (0.015)(0.8611) + (0.5)(0.1158) + 0.00341 - 0.01684 = 0.8927$$

$$\text{N}_2 \text{ balance: } 0.00276 + 2 \times 3.76a_{th} = k \longrightarrow k = 0.00276 + 2 \times 3.76 \times 0.8927 = 6.72$$

Substituting,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO	-110,530	8669
CO ₂	-110,530	8669

Thus,

$$(0.8353)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (0.0258)(-110,530 + \bar{h}_{\text{CO}} - 8669) + (0.1158)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.8927)(0 + \bar{h}_{\text{O}_2} - 8682) + (6.72)(0 + \bar{h}_{\text{N}_2} - 8669) = 0$$

It yields $0.8353\bar{h}_{\text{CO}_2} + 0.0258\bar{h}_{\text{CO}} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.8927\bar{h}_{\text{O}_2} + 6.72\bar{h}_{\text{N}_2} = 434,760 \text{ kJ}$

The product temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields

$$434,760 / (0.8353 + 0.0258 + 0.1158 + 0.00341 + 6.72 + 0.8927) = 50,595 \text{ kJ/kmol.}$$

This enthalpy value corresponds to about 1600 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 1600 K, but somewhat under it because of the higher specific heat of H₂O.

At 1500 K:

$$\begin{aligned} & 0.8353\bar{h}_{\text{CO}_2} + 0.0258\bar{h}_{\text{CO}} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9095\bar{h}_{\text{O}_2} + 6.842\bar{h}_{\text{N}_2} \\ &= (0.8353)(71,078) + (0.0258)(47,517) + (0.1158)(57,999) + (0.8927)(49,292) + (6.72)(47,073) \\ &= 427,647 \text{ kJ} \quad (\text{Lower than } 434,760 \text{ kJ}) \end{aligned}$$

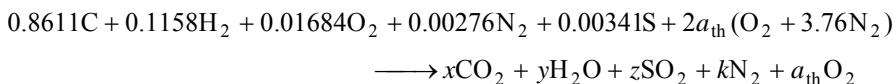

At 1520 K:

$$\begin{aligned} & 0.8353\bar{h}_{\text{CO}_2} + 0.0258\bar{h}_{\text{CO}} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9095\bar{h}_{\text{O}_2} + 6.842\bar{h}_{\text{N}_2} \\ &= (0.8353)(72,246) + (0.0258)(48,222) + (0.1158)(58,942) + (0.8927)(50,024) + (6.72)(47,771) \\ &= 434,094 \text{ kJ} \quad (\text{Lower than } 434,760 \text{ kJ}) \end{aligned}$$

By extrapolation, $T_P = 1522 \text{ K} = 1249^\circ\text{C}$

We repeat the calculations for the complete combustion now:

The combustion equation in this case may be written as

According to the species balances,

C balance: $x = 0.8611$

H₂ balance: $y = 0.1158$

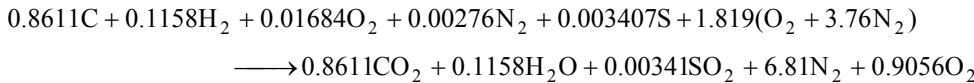

S balance: $z = 0.00341$

O₂ balance:

$$0.01684 + 2a_{\text{th}} = x + 0.5y + z + a_{\text{th}} \longrightarrow a_{\text{th}} = 0.8611 + (0.5)(0.1158) + 0.00341 - 0.01684 = 0.9056$$

$$\text{N}_2 \text{ balance: } 0.00276 + 2 \times 3.76a_{\text{th}} = k \longrightarrow k = 0.00276 + 2 \times 3.76 \times 0.9056 = 6.81$$

Substituting,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO	-110,530	8669
CO ₂	0	8682

Thus,

$$\begin{aligned} (0.8611)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (0.1158)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) \\ + (0.9056)(0 + \bar{h}_{\text{O}_2} - 8682) + (6.81)(0 + \bar{h}_{\text{N}_2} - 8669) = 0 \end{aligned}$$

It yields $0.8611\bar{h}_{\text{CO}_2} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9056\bar{h}_{\text{O}_2} + 6.81\bar{h}_{\text{N}_2} = 442,971 \text{ kJ}$

The product temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields

$$442,971 / (0.8611 + 0.1158 + 0.00341 + 6.81 + 0.9056) = 50,940 \text{ kJ/kmol.}$$

This enthalpy value corresponds to about 1600 K for N₂. Noting that the majority of the moles are N₂, T_p will be close to 1600 K, but somewhat under it because of the higher specific heat of H₂O.

At 1500 K:

$$\begin{aligned} 0.8611\bar{h}_{\text{CO}_2} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9056\bar{h}_{\text{O}_2} + 6.81\bar{h}_{\text{N}_2} \\ = (0.8611)(71,078) + (0.1158)(57,999) + (0.9056)(49,292) + (6.81)(47,073) \\ = 433,128 \text{ kJ} \quad (\text{Lower than } 442,971 \text{ kJ}) \end{aligned}$$

At 1520 K:

$$\begin{aligned} 0.8611\bar{h}_{\text{CO}_2} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9056\bar{h}_{\text{O}_2} + 6.81\bar{h}_{\text{N}_2} \\ = (0.8611)(72,246) + (0.1158)(58,942) + (0.9056)(50,024) + (6.81)(47,771) \\ = 439,658 \text{ kJ} \quad (\text{Lower than } 442,971 \text{ kJ}) \end{aligned}$$

By extrapolation, $T_p = \mathbf{1530 \text{ K} = 1257^\circ\text{C}}$

15-83 A mixture of hydrogen and the stoichiometric amount of air contained in a constant-volume tank is ignited. The final temperature in the tank is to be determined.

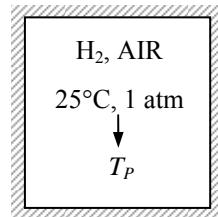

Assumptions 1 The tank is adiabatic. 2 Both the reactants and products are ideal gases. 3 There are no work interactions. 4 Combustion is complete.

Analysis The combustion equation of H₂ with stoichiometric amount of air is

The final temperature in the tank is determined from the energy balance relation $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for reacting closed systems under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$),

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$.

It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_p} - \bar{h}_{298\text{ K}} - R_u T)_P = \sum N_R (\bar{h}_f^\circ R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
H ₂	0	8468
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904

Thus,

$$(1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_p) + (1.88)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_p) \\ = (1)(0 - 8.314 \times 298) + (0.5)(0 - 8.314 \times 298) + (1.88)(0 - 8.314 \times 298)$$

It yields $\bar{h}_{\text{H}_2\text{O}} + 1.88\bar{h}_{\text{N}_2} - 23.94 \times T_p = 259,648 \text{ kJ}$

The temperature of the product gases is obtained from a trial and error solution,

$$\text{At } 3050 \text{ K: } \bar{h}_{\text{H}_2\text{O}} + 1.88\bar{h}_{\text{N}_2} - 23.94 \times T_p = (1)(139,051) + (1.88)(103,260) - (23.94)(3050) \\ = 260,163 \text{ kJ (Higher than } 259,648 \text{ kJ)}$$

$$\text{At } 3000 \text{ K: } \bar{h}_{\text{H}_2\text{O}} + 1.88\bar{h}_{\text{N}_2} - 23.94 \times T_p = (1)(136,264) + (1.88)(101,407) - (23.94)(3000) \\ = 255,089 \text{ kJ (Lower than } 259,648 \text{ kJ)}$$

By interpolation, $T_p = 3045 \text{ K}$

15-84 Methane is burned with 300 percent excess air adiabatically in a constant volume container. The final pressure and temperature of product gases are to be determined.

Assumptions 1 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

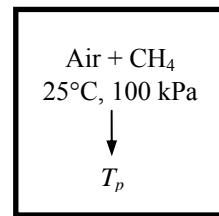

Analysis The combustion equation is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$4a_{\text{th}} = 1 + 1 + 3a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

Substituting, $\text{CH}_4 + 8[\text{O}_2 + 3.76\text{N}_2] \longrightarrow \text{CO}_2 + 2\text{H}_2\text{O} + 30.08\text{N}_2 + 6\text{O}_2$

For this constant-volume process, the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - R_u T)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - R_u T)_R$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
$\text{CH}_4(g)$	-74,850	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$\begin{aligned} & (1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_p) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_p) \\ & + (6)(0 + \bar{h}_{\text{O}_2} - 8682 - 8.314 \times T_p) + (30.08)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_p) \\ & = (1)(-74,850 - 8.314 \times 298) + (8)(0 - 8.314 \times 298) + (30.08)(-8.314 \times 298) \end{aligned}$$

It yields $\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 6\bar{h}_{\text{O}_2} + 30.08\bar{h}_{\text{N}_2} - 324.9T_p = -171,674 + 1,219,188 = 1,047,514 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess may be obtained by assuming all the products are nitrogen and using nitrogen enthalpy in the above equation. That is,

$$39.08\bar{h}_{\text{N}_2} - 324.9T_p = 1,047,514 \text{ kJ}$$

An investigation of Table A-18 shows that this equation is satisfied at a temperature close to 1200 K but it will be somewhat under it because of the higher specific heat of H_2O .

$$\begin{aligned} \text{At } 1100 \text{ K:} \quad & (48,258) + (2)(40,071) + (6)(34,899) + (30.08)(33,426) - (324.9)(1100) = 985,858 \\ & \qquad \qquad \qquad \text{(Lower than } 1,047,514 \text{ kJ)} \end{aligned}$$

$$\begin{aligned} \text{At } 1200 \text{ K:} \quad & (53,848) + (2)(44,380) + (6)(38,447) + (30.08)(36,777) - (324.9)(1200) = 1,089,662 \\ & \qquad \qquad \qquad \text{(Higher than } 1,047,514 \text{ kJ)} \end{aligned}$$

By interpolation, $T_p = 1159 \text{ K}$

The volume of reactants when 1 kmol of fuel is burned is

$$V = V_{\text{fuel}} + V_{\text{air}} = (N_{\text{fuel}} + N_{\text{air}}) \frac{R_u T}{P} = (1 + 38.08) \text{ kmol} \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})}{101.3 \text{ kPa}} = 955.8 \text{ m}^3$$

The final pressure is then

$$P = N_{\text{prod}} \frac{R_u T}{V} = (39.08 \text{ kmol}) \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(1159 \text{ K})}{955.8 \text{ m}^3} = 394 \text{ kPa}$$

Entropy Change and Second Law Analysis of Reacting Systems

15-85C Assuming the system exchanges heat with the surroundings at T_0 , the increase-in-entropy principle can be expressed as

$$S_{\text{gen}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_0}$$

15-86C By subtracting $R \ln(P/P_0)$ from the tabulated value at 1 atm. Here P is the actual pressure of the substance and P_0 is the atmospheric pressure.

15-87C It represents the reversible work associated with the formation of that compound.

15-88 Hydrogen is burned steadily with oxygen. The reversible work and exergy destruction (or irreversibility) are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The combustion equation is

The H_2 , the O_2 , and the H_2O are at 25°C and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^{\circ} - \sum N_P \bar{g}_{f,P}^{\circ} = N_{\text{H}_2} \bar{g}_{f,\text{H}_2}^{\circ} + N_{\text{O}_2} \bar{g}_{f,\text{O}_2}^{\circ} - N_{\text{H}_2\text{O}} \bar{g}_{f,\text{H}_2\text{O}}^{\circ} = -N_{\text{H}_2\text{O}} \bar{g}_{f,\text{H}_2\text{O}}^{\circ} \\ &= -(2 \text{ kmol})(-237,180 \text{ kJ/kmol}) = \mathbf{474,360 \text{ kJ}} \quad (\text{for } 2 \text{ kmol of H}_2) \end{aligned}$$

since the g_f° of stable elements at 25°C and 1 atm is zero. Therefore, 474,360 kJ of work could be done as 2 kmol of H_2 is burned with 1 kmol of O_2 at 25°C and 1 atm in an environment at the same state. The reversible work in this case represents the exergy of the reactants since the product (the H_2O) is at the state of the surroundings.

This process involves no actual work. Therefore, the reversible work and exergy destruction are identical,

$$X_{\text{destruction}} = \mathbf{474,360 \text{ kJ}} \quad (\text{for } 2 \text{ kmol of H}_2)$$

We could also determine the reversible work without involving the Gibbs function,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R (\bar{h}_f^{\circ} + \bar{h} - \bar{h}^{\circ} - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^{\circ} + \bar{h} - \bar{h}^{\circ} - T_0 \bar{s})_P \\ &= \sum N_R (\bar{h}_f^{\circ} - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^{\circ} - T_0 \bar{s})_P \\ &= N_{\text{H}_2} (\bar{h}_f^{\circ} - T_0 \bar{s})_{\text{H}_2} + N_{\text{O}_2} (\bar{h}_f^{\circ} - T_0 \bar{s})_{\text{O}_2} - N_{\text{H}_2\text{O}} (\bar{h}_f^{\circ} - T_0 \bar{s})_{\text{H}_2\text{O}} \end{aligned}$$

Substituting,

$$W_{\text{rev}} = (2)(0 - 298 \times 130.58) + (1)(0 - 298 \times 205.03) - (2)(-285,830 - 298 \times 69.92) = 474,400 \text{ kJ}$$

which is almost identical to the result obtained before.

15-89 Ethylene gas is burned steadily with 20 percent excess air. The temperature of products, the entropy generation, and the exergy destruction (or irreversibility) are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol of C₂H₄, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$1.2a_{\text{th}} = 2 + 1 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 3$$

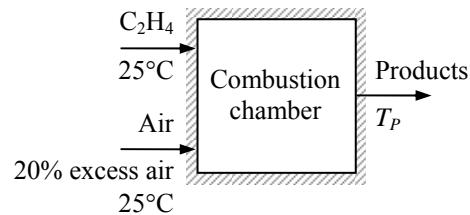

Thus,

Under steady-flow conditions, the exit temperature of the product gases can be determined from the steady-flow energy equation, which reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ = (\bar{N} \bar{h}_f^\circ)_{\text{C}_2\text{H}_4}$$

since all the reactants are at the standard reference state, and for O₂ and N₂. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
C ₂ H ₄ (g)	52,280	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO ₂	-393,520	9364

Substituting,

$$(2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.6)(0 + \bar{h}_{\text{O}_2} - 8682) + (13.54)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(52,280)$$

$$\text{or, } 2\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 0.6\bar{h}_{\text{O}_2} + 13.54\bar{h}_{\text{N}_2} = 1,484,083 \text{ kJ}$$

By trial and error,

$$T_P = 2269.6 \text{ K}$$

(b) The entropy generation during this adiabatic process is determined from

$$S_{\text{gen}} = S_P - S_R = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R$$

The C₂H₄ is at 25°C and 1 atm, and thus its absolute entropy is 219.83 kJ/kmol·K (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C ₂ H ₄	1	1.00	219.83	---	219.83
O ₂	3.6	0.21	205.14	-12.98	784.87
N ₂	13.54	0.79	191.61	-1.96	2620.94
					$S_R = 3625.64 \text{ kJ/K}$
CO ₂	2	0.1103	316.881	-18.329	670.42
H ₂ O	2	0.1103	271.134	-18.329	578.93
O ₂	0.6	0.0331	273.467	-28.336	181.08
N ₂	13.54	0.7464	256.541	-2.432	3506.49
					$S_P = 4936.92 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R = 4936.92 - 3625.64 = \mathbf{1311.28 \text{ kJ/kmol}\cdot\text{K}}$$

and

$$(c) \quad X_{\text{destroyed}} = T_0 S_{\text{gen}} = (298 \text{ K})(1311.28 \text{ kJ/kmol}\cdot\text{K} \text{ C}_2\text{H}_4) = \mathbf{390,760 \text{ kJ (per kmol C}_2\text{H}_4)}$$

15-90 Liquid octane is burned steadily with 50 percent excess air. The heat transfer rate from the combustion chamber, the entropy generation rate, and the reversible work and exergy destruction rate are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol C₈H₁₈, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$1.5a_{\text{th}} = 8 + 4.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Thus,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 25°C. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$T_0 = 298 \text{ K}$		
C ₈ H ₁₈ (<i>l</i>)	-249,950			
O ₂	0			
N ₂	0			
H ₂ O(<i>l</i>)	-285,830			
CO ₂	-393,520			

Substituting,

$$-\dot{Q}_{\text{out}} = (8)(-393,520) + (9)(-285,830) + 0 + 0 - (1)(-249,950) - 0 - 0 = -5,470,680 \text{ kJ/kmol of C}_8\text{H}_{18} \text{ or}$$

$$\dot{Q}_{\text{out}} = 5,470,680 \text{ kJ/kmol of C}_8\text{H}_{18}$$

The C₈H₁₈ is burned at a rate of 0.25 kg/min or

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.25 \text{ kg/min}}{[(8)(12) + (18)(1)] \text{ kg/kmol}} = 2.193 \times 10^{-3} \text{ kmol/min}$$

Thus,

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = (2.193 \times 10^{-3} \text{ kmol/min})(5,470,680 \text{ kJ/kmol}) = 11,997 \text{ kJ/min}$$

The heat transfer for this process is also equivalent to the enthalpy of combustion of liquid C₈H₁₈, which could easily be determined from Table A-27 to be $\bar{h}_C = 5,470,740 \text{ kJ/kmol C}_8\text{H}_{18}$.

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{\dot{Q}_{\text{out}}}{T_{\text{surr}}} \longrightarrow S_{\text{gen}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{\dot{Q}_{\text{out}}}{T_{\text{surr}}}$$

The C₈H₁₈ is at 25°C and 1 atm, and thus its absolute entropy is $\bar{s}_{C_8H_{18}} = 360.79 \text{ kJ/kmol}\cdot\text{K}$ (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N _i	y _i	$\bar{s}_i^\circ(T, 1\text{atm})$	R _u ln(y _i P _m)	N _i \bar{s}_i
C ₈ H ₁₈	1	1.00	360.79	---	360.79
O ₂	18.75	0.21	205.14	-12.98	4089.75
N ₂	70.50	0.79	191.61	-1.96	13646.69
$S_R = 18,097.23 \text{ kJ/K}$					
CO ₂	8	0.0944	213.80	-19.62	1867.3
H ₂ O (l)	9	---	69.92	---	629.3
O ₂	6.25	0.0737	205.04	-21.68	1417.6
N ₂	70.50	0.8319	191.61	-1.53	13,616.3
$S_P = 17,531 \text{ kJ/K}$					

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{surr}}}{T_{\text{surr}}} = 17,531 - 18,097 + \frac{5,470,523 \text{ kJ}}{298 \text{ K}} = 17,798 \text{ kJ/kmol}\cdot\text{K}$$

and

$$\dot{S}_{\text{gen}} = \dot{N}S_{\text{gen}} = (2.193 \times 10^{-3} \text{ kmol/min})(17,798 \text{ kJ/kmol}\cdot\text{K}) = \mathbf{39.03 \text{ kJ/min}\cdot\text{K}}$$

(c) The exergy destruction rate associated with this process is determined from

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(39.03 \text{ kJ/min}\cdot\text{K}) = 11,632 \text{ kJ/min} = \mathbf{193.9 \text{ kW}}$$

15-91E Benzene gas is burned steadily with 90 percent theoretical air. The heat transfer rate from the combustion chamber and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and the combustion gases are ideal gases. 3 Changes in kinetic and potential energies are negligible.

Analysis (a) The fuel is burned with insufficient amount of air, and thus the products will contain some CO as well as CO₂, H₂O, and N₂. The theoretical combustion equation of C₆H₆ is

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$a_{\text{th}} = 6 + 1.5 = 7.5$$

Then the actual combustion equation can be written as

The value of x is determined from an O₂ balance,

$$(0.90)(7.5) = x + (6-x)/2 + 1.5 \longrightarrow x = 4.5$$

Thus,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 77°F. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$.

From the tables,

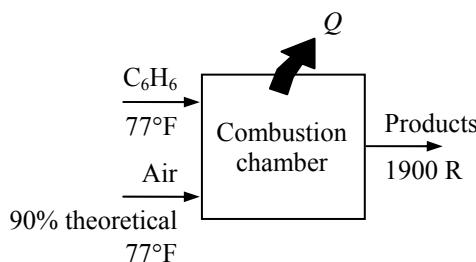

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{R}}$ Btu/lbmol	$\bar{h}_{1900\text{R}}$ Btu/lbmol
C ₆ H ₆ (g)	35,680	---	---
O ₂	0	3725.1	14,322
N ₂	0	3729.5	13,742
H ₂ O (g)	-104,040	4258.0	16,428
CO	-47,540	3725.1	13,850
CO ₂	-169,300	4027.5	19,698

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (4.5)(-169,300 + 19,698 - 4027.5) + (1.5)(-47,540 + 13,850 - 3725.1) \\ &\quad + (3)(-104,040 + 16,428 - 4258) + (25.38)(0 + 13,742 - 3729.5) - (1)(35,680) - 0 - 0 \\ &= -804,630 \text{ Btu/lbmol of C}_6\text{H}_6 \end{aligned}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The C₆H₆ is at 77°F and 1 atm, and thus its absolute entropy is $\bar{s}_{C_6H_6} = 64.34 \text{ Btu/lbmol}\cdot\text{R}$ (Table A-26E). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N _i	y _i	$\bar{s}_i^\circ(T, 1\text{atm})$	R _u ln(y _i P _m)	N _i \bar{s}_i
C ₆ H ₆	1	1.00	64.34	---	64.34
O ₂	6.75	0.21	49.00	-3.10	351.68
N ₂	25.38	0.79	45.77	-0.47	1173.57
					$S_R = 1589.59 \text{ Btu/R}$
CO ₂	4.5	0.1309	64.999	-4.038	310.67
CO	1.5	0.0436	56.509	-6.222	94.10
H ₂ O (g)	3	0.0873	56.097	-4.843	182.82
N ₂	25.38	0.7382	54.896	-0.603	1408.56
					$S_P = 1996.15 \text{ Btu/R}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 1996.15 - 1589.59 + \frac{804,630}{537} = 1904.9 \text{ Btu/R}$$

Then the exergy destroyed is determined from

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (537 \text{ R})(1904.9 \text{ Btu/lbmol}\cdot\text{R}) = \mathbf{1,022,950 \text{ Btu/R}} \text{ (per lbmol C}_6\text{H}_6\text{)}$$

15-92 Liquid propane is burned steadily with 150 percent excess air. The mass flow rate of air, the heat transfer rate from the combustion chamber, and the rate of entropy generation are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of C_3H_8 and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of C_3H_8 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$2.5a_{th} = 3 + 2 + 1.5a_{th} \longrightarrow a_{th} = 5$$

Substituting,

The air-fuel ratio for this combustion process is

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = 39.2 \text{ kg air/kg fuel}$$

Thus,

$$\dot{m}_{air} = (AF)(\dot{m}_{fuel}) = (39.2 \text{ kg air/kg fuel})(0.4 \text{ kg fuel/min}) = \mathbf{15.7 \text{ kg air/min}}$$

(b) Under steady-flow conditions the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables, (The \bar{h}_f° of liquid propane is obtained by adding the h_{fg} at 25°C to \bar{h}_f° of gaseous propane).

Substance	\bar{h}_f°	$\bar{h}_{285 \text{ K}}$	$\bar{h}_{298 \text{ K}}$	$\bar{h}_{1200 \text{ K}}$
	kJ/kmol	kJ/kmol	kJ/kmol	kJ/kmol
$C_3H_8(\ell)$	-118,910	---	---	---
O_2	0	8296.5	8682	38,447
N_2	0	8286.5	8669	36,777
$H_2O(g)$	-241,820	---	9904	44,380
CO_2	-393,520	---	9364	53,848

Thus,

$$\begin{aligned} -Q_{out} &= (3)(-393,520 + 53,848 - 9364) + (4)(-241,820 + 44,380 - 9904) \\ &\quad + (7.5)(0 + 38,447 - 8682) + (47)(0 + 36,777 - 8669) - (1)(-118,910 + h_{298} - h_{298}) \\ &\quad - (12.5)(0 + 8296.5 - 8682) - (47)(0 + 8286.5 - 8669) \\ &= -190,464 \text{ kJ/kmol of } C_3H_8 \end{aligned}$$

Thus 190,464 kJ of heat is transferred from the combustion chamber for each kmol (44 kg) of propane. This corresponds to $190,464/44 = 4328.7$ kJ of heat transfer per kg of propane. Then the rate of heat transfer for a mass flow rate of 0.4 kg/min for the propane becomes

$$\dot{Q}_{\text{out}} = \dot{m}q_{\text{out}} = (0.4 \text{ kg/min})(4328.7 \text{ kJ/kg}) = \mathbf{1732 \text{ kJ/min}}$$

(c) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The C₃H₈ is at 25°C and 1 atm, and thus its absolute entropy for the gas phase is $\bar{s}_{\text{C}_3\text{H}_8} = 269.91 \text{ kJ/kmol}\cdot\text{K}$ (Table A-26).

Then the entropy of C₃H₈(ℓ) is obtained from

$$s_{\text{C}_3\text{H}_8}(\ell) \equiv s_{\text{C}_3\text{H}_8}(g) - s_{fg} = s_{\text{C}_3\text{H}_8}(g) - \frac{\bar{h}_{fg}}{T} = 269.91 - \frac{15,060}{298.15} = 219.4 \text{ kJ/kmol}\cdot\text{K}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^{\circ}(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N _i	y _i	$\bar{s}_i^{\circ}(\mathbf{T}, 1\text{atm})$	R _u ln(y _i P _m)	N _i \bar{s}_i
C ₃ H ₈	1	---	219.40	---	219.40
O ₂	12.5	0.21	203.70	-12.98	2708.50
N ₂	47	0.79	190.18	-1.96	9030.58
					$S_R = 11,958.48 \text{ kJ/K}$
CO ₂	3	0.0488	279.307	-25.112	913.26
H ₂ O (g)	4	0.0650	240.333	-22.720	1052.21
O ₂	7.5	0.1220	249.906	-17.494	2005.50
N ₂	47	0.7642	234.115	-2.236	11108.50
					$S_P = 15,079.47 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 15,079.47 - 11,958.48 + \frac{190,464}{298} = 3760.1 \text{ kJ/K (per kmol C}_3\text{H}_8)$$

Then the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = (\dot{N})(S_{\text{gen}}) = \left(\frac{0.4}{44} \text{ kmol/min} \right) (3760.1 \text{ kJ/kmol}\cdot\text{K}) = \mathbf{34.2 \text{ kJ/min}\cdot\text{K}}$$

15-93 Problem 15-92 is reconsidered. The effect of the surroundings temperature on the rate of exergy destruction is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

```

Fuel$ = 'Propane (C3H8)_liq'

15-94 Liquid octane is burned steadily with 70 percent excess air. The entropy generation and exergy destruction per unit mass of the fuel are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of C₈H₁₈ and air are 114 kg/kmol and 29 kg/kmol, respectively (Table A-1).

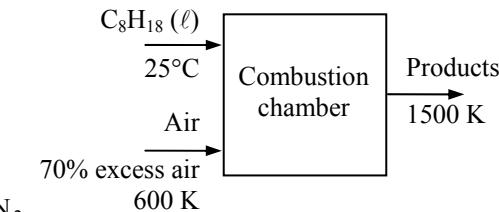

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol C₈H₁₈, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$1.7a_{\text{th}} = 8 + 4.5 + 0.7a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Thus,

(b) Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{600\text{K}}$ kJ/kmol	$\bar{h}_{1500\text{K}}$ kJ/kmol
C ₈ H ₁₈ (ℓ)	-249,950	---	---	---
O ₂	0	8682	17,929	49,292
N ₂	0	8669	17,563	47,073
H ₂ O (g)	-241,820	9904	---	57,999
CO ₂	-393,520	9364	---	71,078

Thus,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (8)(-393,520 + 71,078 - 9364) + (9)(-241,820 + 57,999 - 9904) \\ &\quad + (8.75)(0 + 49,292 - 8682) + (79.9)(0 + 47,073 - 8669) - (1)(-249,950) \\ &\quad - (21.25)(0 + 17,929 - 8682) - (79.9)(0 + 17,563 - 8669) \\ &= -1,631,335 \text{ kJ/kmol of C}_8\text{H}_{18} \end{aligned}$$

The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{\dot{Q}_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{\dot{Q}_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of $P_m = 600 \text{ kPa}$ ($=600/101.325=5.92 \text{ atm}$), but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C ₈ H ₁₈	1	---	466.73	14.79	451.94
O ₂	21.25	0.21	226.35	1.81	4771.48
N ₂	79.9	0.79	212.07	12.83	15,919.28
					$S_R = 21,142.70 \text{ kJ/K}$
CO ₂	8	0.0757	292.11	-6.673	2390.26
H ₂ O (g)	9	0.0852	250.45	-5.690	2305.26
O ₂	8.75	0.0828	257.97	-5.928	2309.11
N ₂	79.9	0.7563	241.77	12.46	18,321.87
					$S_P = 25,326.50 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 25,326.50 - 21,142.70 + \frac{1,631,335}{298} = 9658.1 \text{ kJ/K (per kmol C}_8\text{H}_{18}\text{)}$$

The exergy destruction is

$$X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(9658.1 \text{ kJ/K}) = 2,878,114 \text{ kJ/K (per kmol C}_8\text{H}_{18}\text{)}$$

The entropy generation and exergy destruction per unit mass of the fuel are

$$S_{\text{gen}} = \frac{\bar{S}_{\text{gen}}}{M_{\text{fuel}}} = \frac{9658.1 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{84.72 \text{ kJ/K} \cdot \text{kg C}_8\text{H}_{18}}$$

$$X_{\text{dest}} = \frac{\bar{X}_{\text{dest}}}{M_{\text{fuel}}} = \frac{2,878,114 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{25,250 \text{ kJ/kg C}_8\text{H}_{18}}$$

15-95 Methyl alcohol is burned steadily with 200 percent excess air in an automobile engine. The maximum amount of work that can be produced by this engine is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol CH₃OH the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$0.5 + 3a_{\text{th}} = 1 + 1 + 2a_{\text{th}} \longrightarrow a_{\text{th}} = 1.5$$

Thus,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298\text{K}}$	$\bar{h}_{350\text{K}}$
	kJ/kmol	kJ/kmol	kJ/kmol
CH ₃ OH	-200,670	---	---
O ₂	0	8682	10,213
N ₂	0	8669	10,180
H ₂ O (g)	-241,820	9904	11,652
CO ₂	-393,520	9364	11,351

Thus,

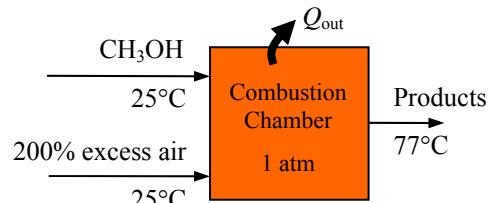

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 11,351 - 9364) + (2)(-241,820 + 11,652 - 9904) \\ &\quad + (3)(0 + 10,213 - 8682) + (16.92)(0 + 10,180 - 8669) - (1)(-200,670) \\ &= -663,550 \text{ kJ/kmol of fuel} \end{aligned}$$

The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
CH ₃ OH	1	---	239.70	---	239.70
O ₂	4.5	0.21	205.04	-12.98	981.09
N ₂	16.92	0.79	191.61	-1.960	3275.20
					$S_R = 4496 \text{ kJ/K}$
CO ₂	1	0.0436	219.831	-26.05	245.88
H ₂ O (g)	2	0.0873	194.125	-20.27	428.79
O ₂	3	0.1309	209.765	-16.91	680.03
N ₂	16.92	0.7382	196.173	-2.52	3361.89
					$S_P = 4717 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 4717 - 4496 + \frac{663,550}{298} = 2448 \text{ kJ/K (per kmol fuel)}$$

The maximum work is equal to the exergy destruction

$$W_{\max} = X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(2448 \text{ kJ/K}) = 729,400 \text{ kJ/K (per kmol fuel)}$$

Per unit mass basis,

$$W_{\max} = \frac{729,400 \text{ kJ/K} \cdot \text{kmol}}{32 \text{ kg/kmol}} = \mathbf{22,794 \text{ kJ/kg fuel}}$$

Review Problems

15-96 A sample of a certain fluid is burned in a bomb calorimeter. The heating value of the fuel is to be determined.

Properties The specific heat of water is 4.18 kJ/kg·°C (Table A-3).

Analysis We take the water as the system, which is a closed system, for which the energy balance on the system

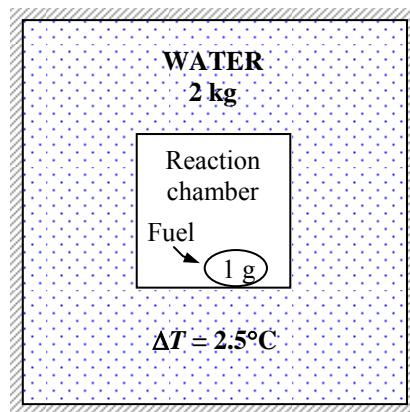

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \text{ with } W = 0 \text{ can be written as}$$

$$Q_{\text{in}} = \Delta U$$

or

$$\begin{aligned} Q_{\text{in}} &= mc\Delta T \\ &= (2 \text{ kg})(4.18 \text{ kJ/kg} \cdot ^{\circ}\text{C})(2.5^{\circ}\text{C}) \\ &= 20.90 \text{ kJ (per gram of fuel)} \end{aligned}$$

Therefore, heat transfer per kg of the fuel would be **20,900 kJ/kg fuel**. Disregarding the slight energy stored in the gases of the combustion chamber, this value corresponds to the heating value of the fuel.

15-97E Hydrogen is burned with 100 percent excess air. The AF ratio and the volume flow rate of air are to be determined.

Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases.

Properties The molar masses of H₂ and air are 2 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The combustion is complete, and thus products will contain only H₂O, O₂ and N₂. The moisture in the air does not react with anything; it simply shows up as additional H₂O in the products. Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } 2a_{\text{th}} = 0.5 + a_{\text{th}} \longrightarrow a_{\text{th}} = 0.5$$

Therefore, 4.76 lbmol of dry air will be used per kmol of the fuel.

The partial pressure of the water vapor present in the incoming air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@90^\circ\text{F}} = (0.60)(0.69904 \text{ psi}) = 0.419 \text{ psia}$$

The number of moles of the moisture that accompanies 4.76 lbmol of incoming dry air ($N_{v,\text{in}}$) is determined to be

$$N_{v,\text{in}} = \left(\frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left(\frac{0.419 \text{ psia}}{14.5 \text{ psia}} \right) (4.76 + N_{v,\text{in}}) \longrightarrow N_{v,\text{in}} = 0.142 \text{ lbmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.142 lbmol of H₂O to both sides of the equation,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(4.76 \text{ lbmol})(29 \text{ lbm/lbmol}) + (0.142 \text{ lbmol})(18 \text{ lbm/lbmol})}{(1 \text{ lbmol})(2 \text{ lbm/lbmol})} = \mathbf{70.3 \text{ lbm air/lbm fuel}}$$

(b) The mass flow rate of H₂ is given to be 10 lbm/h. Since we need 70.3 lbm air per lbm of H₂, the required mass flow rate of air is

$$\dot{m}_{\text{air}} = (\text{AF})(\dot{m}_{\text{fuel}}) = (70.3)(25 \text{ lbm/h}) = 1758 \text{ lbm/h}$$

The mole fractions of water vapor and the dry air in the incoming air are

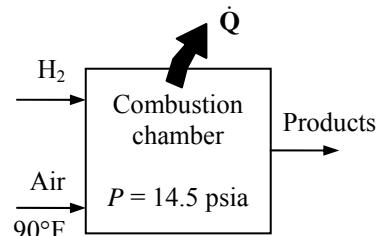

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{0.142}{4.76 + 0.142} = 0.029 \text{ and } y_{\text{dryair}} = 1 - 0.029 = 0.971$$

Thus,

$$M = (yM)_{\text{H}_2\text{O}} + (yM)_{\text{dryair}} = (0.029)(18) + (0.971)(29) = 28.7 \text{ lbm/lbmol}$$

$$\nu = \frac{RT}{P} = \frac{(10.73/28.7 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(550 \text{ R})}{14.5 \text{ psia}} = 14.18 \text{ ft}^3/\text{lbm}$$

$$\dot{V} = \dot{m}\nu = (1758 \text{ lbm/h})(14.18 \text{ ft}^3/\text{lbm}) = \mathbf{24,928 \text{ ft}^3/\text{h}}$$

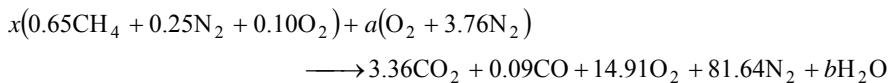

15-98 A gaseous fuel with a known composition is burned with dry air, and the volumetric analysis of products gases is determined. The AF ratio, the percent theoretical air used, and the volume flow rate of air are to be determined.

Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases.

Properties The molar masses of C, H₂, N₂, O₂, and air are 12, 2, 28, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

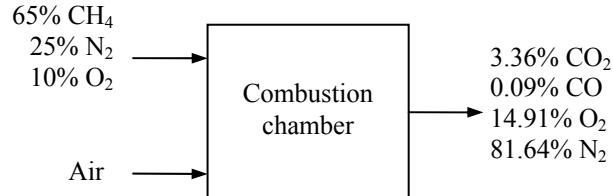

The unknown coefficients x , a , and b are determined from mass balances,

$$\text{C: } 0.65x = 3.36 + 0.09 \longrightarrow x = 5.31$$

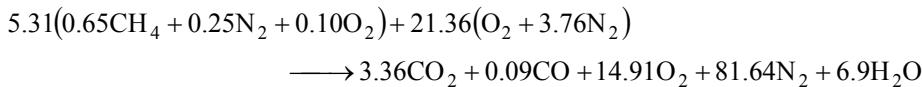

$$\text{H: } (4)(0.65)x = 2b \longrightarrow b = 6.90$$

$$\text{N}_2: 0.25x + 3.76a = 81.64 \longrightarrow a = 21.36$$

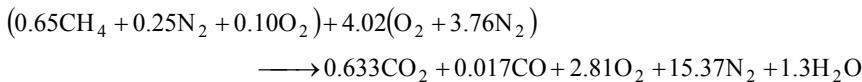

$$[\text{Check O}_2: 0.10x + a = 3.36 + 0.045 + 14.91 + b/2 \longrightarrow a = 21.23]$$

The N₂ balance and O₂ balance gives two different a values. There must be a small error in the volumetric analysis of the products and the mass balance is not completely satisfied. Yet we solve the problem with an a value of 21.36 being aware of this situation. Then,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.31,

(a) The air-fuel ratio is determined from its definition,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(4.02 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{0.65 \times 16 + 0.25 \times 28 + 0.10 \times 32} = \mathbf{26.9 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2: 0.10 + a_{\text{th}} = 0.65 + 0.65 \longrightarrow a_{\text{th}} = 1.2$$

$$\text{Then, Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(4.02)(4.76) \text{ kmol}}{(1.2)(4.76) \text{ kmol}} = 3.35 = \mathbf{335\%}$$

(c) The specific volume, mass flow rate, and the volume flow rate of air at the inlet conditions are

$$\nu = \frac{RT}{P} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{100 \text{ kPa}} = 0.855 \text{ m}^3/\text{kg}$$

$$\dot{m}_{\text{air}} = (\text{AF})\dot{m}_{\text{fuel}} = (26.9 \text{ kg air/kg fuel})(3.5 \text{ kg fuel/min}) = 94.15 \text{ m}^3/\text{min}$$

$$\dot{V}_{\text{air}} = (\dot{m}\nu)_{\text{air}} = (94.15 \text{ kg/min})(0.855 \text{ m}^3/\text{kg}) = \mathbf{80.5 \text{ m}^3/\text{min}}$$

15-99E Propane is burned with stoichiometric amount of air. The fraction of the water in the products that is vapor is to be determined.

Assumptions **1** Combustion is complete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases.

Analysis The fuel is burned completely with the air, and thus the products will contain only CO₂, H₂O, and N₂. Considering 1 kmol C₃H₈, the combustion equation can be written as

The mole fraction of water in the products is

$$y = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{4 \text{ kmol}}{(3 + 4 + 18.8)\text{kmol}} = 0.1550$$

The saturation pressure for the water vapor is

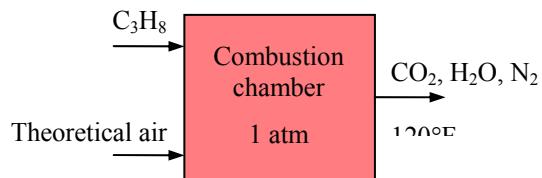

$$P_v = P_{\text{sat}@120^\circ\text{F}} = 1.6951 \text{ psia}$$

When the combustion gases are saturated, the mole fraction of the water vapor will be

$$y_g = \frac{P_v}{P} = \frac{1.6951 \text{ kPa}}{14.696 \text{ kPa}} = 0.1153$$

Thus, the fraction of water vapor in the combustion products is

$$f_{\text{vapor}} = \frac{y_g}{y} = \frac{0.1153}{0.1550} = \mathbf{0.744}$$

15-100 Coal whose mass percentages are specified is burned with 20% excess air. The dew-point temperature of the products is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, CO, H₂O, SO₂, and N₂. 3 Combustion gases are ideal gases.

Properties The molar masses of C, H₂, O₂, S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{61.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.117 \text{ kmol}$$

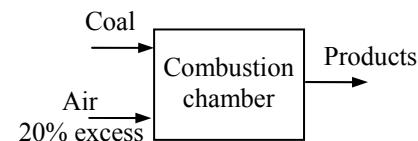

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.79 \text{ kg}}{2 \text{ kg/kmol}} = 2.895 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{25.31 \text{ kg}}{32 \text{ kg/kmol}} = 0.7909 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1.09 \text{ kg}}{28 \text{ kg/kmol}} = 0.03893 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{1.41 \text{ kg}}{32 \text{ kg/kmol}} = 0.04406 \text{ kmol}$$

61.40% C
5.79% H ₂
25.31% O ₂
1.09% N ₂
1.41% S
5.00% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.117 + 2.895 + 0.7909 + 0.03893 + 0.04406 = 8.886 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{5.117 \text{ kmol}}{8.886 \text{ kmol}} = 0.5758$$

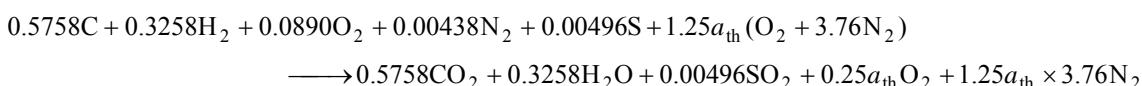

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.895 \text{ kmol}}{8.886 \text{ kmol}} = 0.3258$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.7909 \text{ kmol}}{8.886 \text{ kmol}} = 0.0890$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.03893 \text{ kmol}}{8.886 \text{ kmol}} = 0.00438$$

$$y_S = \frac{N_S}{N_m} = \frac{0.04406 \text{ kmol}}{8.886 \text{ kmol}} = 0.00496$$

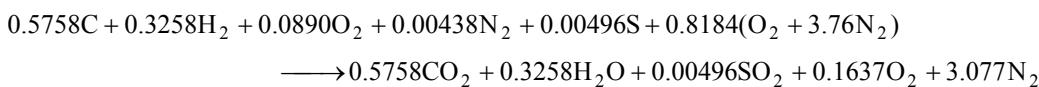

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the oxygen balance,

$$O_2 \text{ balance: } 0.0890 + 1.25a_{th} = 0.5758 + 0.5 \times 0.3258 + 0.00496 + 0.25a_{th} \longrightarrow a_{th} = 0.6547$$

Substituting,

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{prod}} \right) P_{prod} = \left(\frac{0.3258 \text{ kmol}}{(0.5758 + 0.3258 + 0.00496 + 0.1637 + 3.077) \text{ kmol}} \right) (101.3 \text{ kPa}) = 7.96 \text{ kPa}$$

Thus, $T_{dp} = T_{sat@7.96 \text{ kPa}} = 41.3^\circ\text{C}$ (Table A-5)

15-101 Methane is burned steadily with 50 percent excess air. The dew-point temperature of the water vapor in the products is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.

Properties The molar masses of CH₄ and air are 16 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol CH₄, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$1.5a_{\text{th}} = 1 + 1 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

Thus,

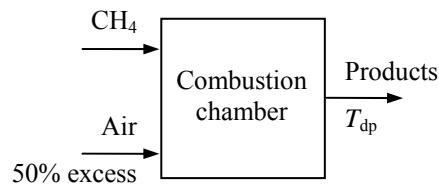

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{2 \text{ kmol}}{(1+2+1+11.28) \text{ kmol}} \right) (101.325 \text{ kPa}) = 13.26 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@13.26 \text{ kPa}} = 51.4^\circ\text{C} \quad (\text{from EES})$$

15-102 A mixture of 40% by volume methane, CH₄, and 60% by volume propane, C₃H₈, is burned completely with theoretical air. The amount of water formed during combustion process that will be condensed is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance: } B = 0.4 + 3 \times 0.6 = 2.2$$

$$\text{Hydrogen balance: } 2D = 4 \times 0.4 + 8 \times 0.6 = 2D \longrightarrow D = 3.2$$

$$\text{Oxygen balance: } 2a_{\text{th}} = 2B + D \longrightarrow 2a_{\text{th}} = 2(2.2) + 3.2 \longrightarrow a_{\text{th}} = 3.8$$

$$\text{Nitrogen balance: } 3.76a_{\text{th}} = F \longrightarrow 3.76(3.8) = F \longrightarrow F = 14.29$$

Then, we write the balanced reaction equation as

The vapor mole fraction in the products is

$$y_v = \frac{3.2}{2.2 + 3.2 + 14.29} = 0.1625$$

The partial pressure of water in the products is

$$P_{v,\text{prod}} = y_v P_{\text{prod}} = (0.1625)(100 \text{kPa}) = 16.25 \text{kPa}$$

The dew point temperature of the products is

$$T_{dp} = T_{\text{sat}@16.25 \text{kPa}} = 55.64^\circ\text{C}$$

The partial pressure of the water vapor remaining in the products at the product temperature is

$$P_v = P_{\text{sat}@39^\circ\text{C}} = 7.0 \text{kPa}$$

The kmol of water vapor in the products at the product temperature is

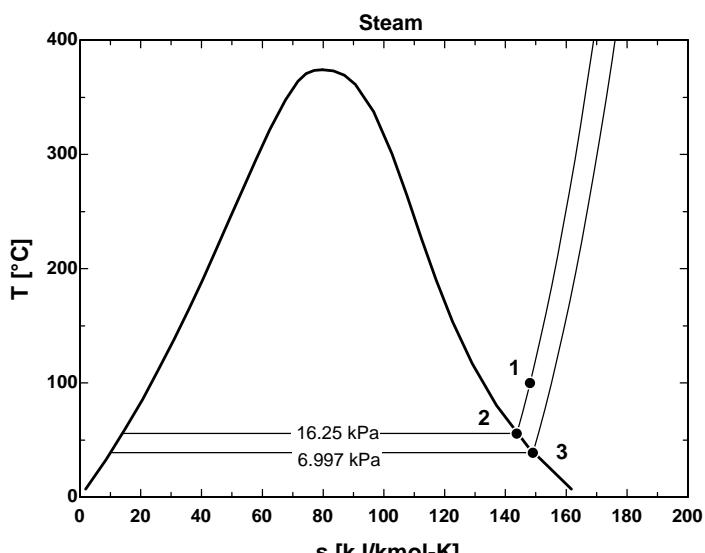

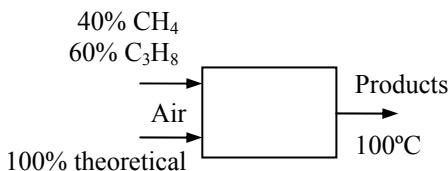

$$P_v = \frac{N_v}{N_{\text{total,product}}} P_{\text{prod}}$$

$$7.0 \text{kPa} = \frac{N_v}{2.2 + N_v + 14.29}$$

$$N_v = 1.241 \text{ kmol}$$

The kmol of water condensed is

$$N_w = 3.2 - 1.241 = \mathbf{1.96 \text{ kmol water/kmol fuel}}$$

15-103 A gaseous fuel mixture of 60% propane, C₃H₈, and 40% butane, C₄H₁₀, on a volume basis is burned with an air-fuel ratio of 25. The moles of nitrogen in the air supplied to the combustion process, the moles of water formed in the combustion process, and the moles of oxygen in the product gases are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The theoretical combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance: } B = 3 \times 0.6 + 4 \times 0.4 = 3.4$$

$$\text{Hydrogen balance: } 8 \times 0.6 + 10 \times 0.4 = 2D \longrightarrow D = 4.4$$

$$\text{Oxygen balance: } 2a_{\text{th}} = 2B + D \longrightarrow 2a_{\text{th}} = 2 \times 3.4 + 4.4 \longrightarrow a_{\text{th}} = 5.6$$

$$\text{Nitrogen balance: } 3.76a_{\text{th}} = F \longrightarrow 3.76 \times 5.6 = F \longrightarrow F = 21.06$$

Then, we write the balanced theoretical reaction equation as

The air-fuel ratio for the theoretical reaction is determined from

$$\text{AF}_{\text{th}} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(5.6 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(0.6 \times 44 + 0.4 \times 58) \text{ kg}} = 15.59 \text{ kg air/kg fuel}$$

The percent theoretical air is

$$\text{PercentTH}_{\text{air}} = \frac{\text{AF}_{\text{actual}}}{\text{AF}_{\text{th}}} = \frac{25}{15.59} \times 100 = 160.4\%$$

The moles of nitrogen supplied is

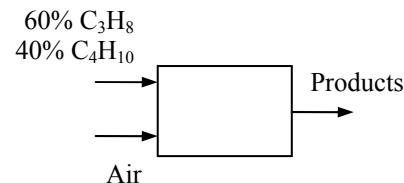

$$N_{\text{N}_2} = \frac{\text{PercentTH}_{\text{air}}}{100} \times a_{\text{th}} \times 3.76 = \frac{160.4}{100} (5.6)(3.76) = \mathbf{33.8 \text{ kmol per kmol fuel}}$$

The moles of water formed in the combustion process is

$$N_{\text{H}_2\text{O}} = D = \mathbf{4.4 \text{ kmol per kmol fuel}}$$

The moles of oxygen in the product gases is

$$N_{\text{O}_2} = \left(\frac{\text{PercentTH}_{\text{air}}}{100} - 1 \right) a_{\text{th}} = \left(\frac{160.4}{100} - 1 \right) (5.6) = \mathbf{3.38 \text{ kmol per kmol fuel}}$$

15-104 Ethane is completely burned with air. Various parameters are to be determined for the given reaction.

Assumptions The water in the products is in the vapor phase.

Analysis (a) The reaction equation is given as

The partial pressure of water vapor is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{3}{2 + 3 + 1.288 + 18} (100 \text{ kPa}) = \frac{3 \text{ kmol}}{24.288 \text{ kmol}} (100 \text{ kPa}) = 12.35 \text{ kPa}$$

The dew point temperature of the product gases is the saturation temperature of water at this pressure:

$$T_{dp} = T_{\text{sat}@12.35 \text{ kPa}} = 49.6^\circ\text{C} \quad (\text{Table A-5})$$

(b) The partial pressure of oxygen is

$$P_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{total}}} P_{\text{total}} = \frac{1.288 \text{ kmol}}{24.288 \text{ kmol}} (100 \text{ kPa}) = 5.303 \text{ kPa}$$

The specific volume of oxygen is then,

$$v_{\text{O}_2} = \frac{R_{\text{O}_2} T}{P_{\text{O}_2}} = \frac{(0.2598 \text{ kJ/kmol} \cdot \text{K})(373 \text{ K})}{5.303 \text{ kPa}} = 18.3 \text{ m}^3/\text{kg}$$

(c) The combustion reaction with stoichiometric air is

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P} - \sum N_R \bar{h}_{f,R} = (N \bar{h}_f)_{\text{CO}_2} + (N \bar{h}_f)_{\text{H}_2\text{O}} - (N \bar{h}_f)_{\text{C}_2\text{H}_6}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$\begin{aligned} h_C &= (2 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (3 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-84,680 \text{ kJ/kmol}) \\ &= -1,427,820 \text{ kJ/kmol ethane} \end{aligned}$$

The LHV per unit kmol of the fuel is the negative of the enthalpy of combustion:

$$\text{LHV} = -h_C = 1,427,820 \text{ kJ/kmol C}_2\text{H}_6$$

(d) The average molar mass of the product gas is

$$\begin{aligned} M &= \frac{N_{\text{CO}_2} M_{\text{CO}_2} + N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} + N_{\text{O}_2} M_{\text{O}_2} + N_{\text{N}_2} M_{\text{N}_2}}{N_{\text{total}}} \\ &= \frac{(2 \text{ kmol})(44 \text{ kg/kmol}) + (3 \text{ kmol})(18 \text{ kg/kmol}) + (1.288 \text{ kmol})(32 \text{ kg/kmol}) + (18 \text{ kmol})(28 \text{ kg/kmol})}{24.288 \text{ kmol}} \\ &= \frac{687.2 \text{ kmol}}{24.288 \text{ kmol}} = 28.29 \text{ kg/kmol} \end{aligned}$$

(e) The average molar constant pressure specific heat of the product gas is

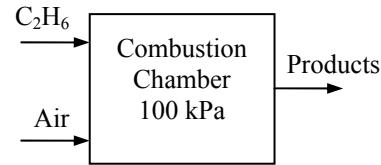

$$\begin{aligned} \bar{c}_p &= \frac{N_{\text{CO}_2} \bar{c}_{p,\text{CO}_2} + N_{\text{H}_2\text{O}} \bar{c}_{p,\text{H}_2\text{O}} + N_{\text{O}_2} \bar{c}_{p,\text{O}_2} + N_{\text{N}_2} \bar{c}_{p,\text{N}_2}}{N_{\text{total}}} \\ &= \frac{(2 \times 41.16 + 3 \times 34.28 + 1.288 \times 30.14 + 18 \times 29.27) \text{ kJ/K}}{24.288 \text{ kmol}} = \frac{750.8 \text{ kJ/K}}{24.288 \text{ kmol}} = 30.91 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

(f) The air-fuel mass ratio is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(4.788 \times 4.76 \times 29) \text{ kg}}{(1 \times 30) \text{ kg}} = \frac{660.9 \text{ kg}}{30 \text{ kg}} = 22.03 \text{ kg air/kg fuel}$$

(g) For a molar fuel flow rate is 0.1 kmol/min, the mass flow rate of water in the product gases is

$$\dot{m}_{\text{H}_2\text{O}} = \dot{N}_{\text{C}_2\text{H}_6} \frac{N_{\text{H}_2\text{O}}}{N_{\text{C}_2\text{H}_6}} M_{\text{H}_2\text{O}} = (0.1 \text{ kmol/min}) \frac{3 \text{ kmol}}{1 \text{ kmol}} (18 \text{ kg/kmol}) = 5.4 \text{ kg/min}$$

15-105 CO gas is burned with air during a steady-flow combustion process. The rate of heat transfer from the combustion chamber is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 Combustion is complete.

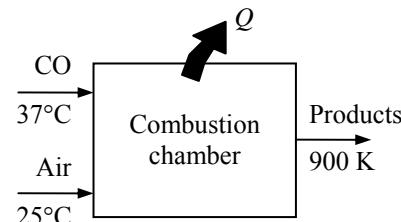

Properties The molar masses of CO and air are 28 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis We first need to calculate the amount of air used per kmol of CO before we can write the combustion equation,

$$\nu_{\text{CO}} = \frac{RT}{P} = \frac{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(310 \text{ K})}{(110 \text{ kPa})} = 0.836 \text{ m}^3/\text{kg}$$

$$\dot{m}_{\text{CO}} = \frac{\dot{V}_{\text{CO}}}{\nu_{\text{CO}}} = \frac{0.4 \text{ m}^3/\text{min}}{0.836 \text{ m}^3/\text{kg}} = 0.478 \text{ kg/min}$$

Then the molar air-fuel ratio becomes

$$\overline{\text{AF}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{\dot{m}_{\text{air}} / M_{\text{air}}}{\dot{m}_{\text{fuel}} / M_{\text{fuel}}} = \frac{(1.5 \text{ kg/min}) / (29 \text{ kg/kmol})}{(0.478 \text{ kg/min}) / (28 \text{ kg/kmol})} = 3.03 \text{ kmol air/kmol fuel}$$

Thus the number of moles of O₂ used per mole of CO is 3.03/4.76 = 0.637. Then the combustion equation in this case can be written as

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298 \text{ K}}$	$\bar{h}_{310 \text{ K}}$	$\bar{h}_{900 \text{ K}}$
	kJ/kmol	kJ/kmol	kJ/kmol	kJ/kmol
CO	-110,530	8669	9014	27,066
O ₂	0	8682	---	27,928
N ₂	0	8669	---	26,890
CO ₂	-393,520	9364	---	37,405

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 37,405 - 9364) + (0.137)(0 + 27,928 - 8682) \\ &\quad + (2.4)(0 + 26,890 - 8669) - (1)(-110,530 + 9014 - 8669) - 0 - 0 \\ &= -208,927 \text{ kJ/kmol of CO} \end{aligned}$$

Then the rate of heat transfer for a mass flow rate of 0.956 kg/min for CO becomes

$$\dot{Q}_{\text{out}} = \dot{N}Q_{\text{out}} = \left(\frac{\dot{m}}{N} \right) Q_{\text{out}} = \left(\frac{0.478 \text{ kg/min}}{28 \text{ kg/kmol}} \right) (208,927 \text{ kJ/kmol}) = 3567 \text{ kJ/min}$$

15-106 Ethanol gas is burned with 10% excess air. The combustion is incomplete. The theoretical kmols of oxygen in the reactants, the balanced chemical reaction, and the rate of heat transfer are to be determined.

Assumptions 1 Combustion is incomplete. 2 The combustion products contain CO₂, CO, H₂O, O₂, and N₂ only.

Properties The molar masses of C, H₂, O₂, N₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O₂ balance:

$$0.5 + a_{\text{th}} = 2 + 1.5 \longrightarrow a_{\text{th}} = 3$$

Substituting,

Therefore, **3 kmol of oxygen** is required to burn 1 kmol of ethanol.

(b) The reaction with 10% excess air and incomplete combustion can be written as

The coefficient for O₂ is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 0.5 + 1.1 \times 3 = 0.9 \times 2 + 0.5 \times (0.1 \times 2) + 0.5 \times 3 + x \longrightarrow x = 0.4$$

Substituting,

(b) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Both the reactants and products are at 25 °C. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. Then, using the values given in the table,

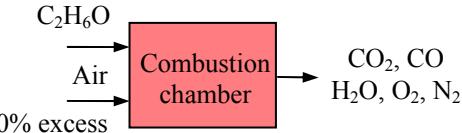

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (1.8)(-393,520) + (0.2)(-110,530) + (3)(-241,820) - (1)(-235,310) \\ &= -1,220,590 \text{ kJ/kmol fuel} \end{aligned}$$

or

$$\dot{Q}_{\text{out}} = 1,220,590 \text{ kJ/kmol fuel}$$

For a 3.5 kg/h of fuel burned, the rate of heat transfer is

$$\dot{Q}_{\text{out}} = \dot{N} \dot{Q}_{\text{out}} = \left(\frac{\dot{m}}{M} \right) \dot{Q}_{\text{out}} = \frac{3.5 \text{ kg/h}}{46 \text{ kg/kmol}} (1,220,590 \text{ kJ/kmol}) = 92,870 \text{ kJ/h} = \mathbf{25.80 \text{ kW}}$$

15-107 Propane gas is burned with air during a steady-flow combustion process. The adiabatic flame temperature is to be determined for different cases.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$). Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h}_T - \bar{h}^\circ)_P = (N \bar{h}_f^\circ)_{C_3H_8}$$

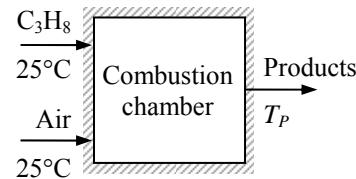

since all the reactants are at the standard reference temperature of 25°C, and $\bar{h}_f^\circ = 0$ for O₂ and N₂.

(a) The theoretical combustion equation of C₃H₈ with stoichiometric amount of air is

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
C ₃ H ₈ (g)	-103,850	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO	-110,530	8669
CO ₂	-393,520	9364

Thus,

$$(3)(-393,520 + \bar{h}_{CO_2} - 9364) + (4)(-241,820 + \bar{h}_{H_2O} - 9904) + (18.8)(0 + \bar{h}_{N_2} - 8669) = (1)(-103,850)$$

It yields

$$3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} = 2,274,675 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,274,675 / (3 + 4 + 18.8) = 88,165 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2650 K for N₂. Noting that the majority of the moles are N₂, T_p will be close to 2650 K, but somewhat under it because of the higher specific heats of CO₂ and H₂O.

$$\begin{aligned} \text{At 2400 K: } & 3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} = (3)(125,152) + (4)(103,508) + (18.8)(79,320) \\ & = 2,280,704 \text{ kJ (Higher than 2,274,675 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At 2350 K: } & 3\bar{h}_{CO_2} + 4\bar{h}_{H_2O} + 18.8\bar{h}_{N_2} = (3)(122,091) + (4)(100,846) + (18.8)(77,496) \\ & = 2,226,582 \text{ kJ (Lower than 2,274,675 kJ)} \end{aligned}$$

By interpolation, $T_p = 2394 \text{ K}$

(b) The balanced combustion equation for complete combustion with 200% theoretical air is

Substituting known numerical values,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) \\ + (5)(0 + \bar{h}_{\text{O}_2} - 8682) + (37.6)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

which yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 37.6\bar{h}_{\text{N}_2} = 2,481,060 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,481,060 / (3 + 4 + 5 + 37.6) = 50,021 \text{ kJ/kmol}$. This enthalpy value corresponds to about 1580 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 1580 K, but somewhat under it because of the higher specific heats of CO₂ and H₂O.

$$\text{At 1540 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 37.6\bar{h}_{\text{N}_2} = (3)(73,417) + (4)(59,888) + (5)(50,756) + (37.6)(48,470) \\ = 2,536,055 \text{ kJ} \text{ (Higher than 2,481,060 kJ)}$$

$$\text{At 1500 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 37.6\bar{h}_{\text{N}_2} = (3)(71,078) + (4)(57,999) + (5)(49,292) + (37.6)(47,073) \\ = 2,461,630 \text{ kJ} \text{ (Lower than 2,481,060 kJ)}$$

By interpolation, $T_P = \mathbf{1510 \text{ K}}$

(c) The balanced combustion equation for incomplete combustion with 95% theoretical air is

Substituting known numerical values,

$$(2.5)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (0.5)(-110,530 + \bar{h}_{\text{CO}} - 8669) \\ + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (17.86)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

which yields

$$2.5\bar{h}_{\text{CO}_2} + 0.5\bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 17.86\bar{h}_{\text{N}_2} = 2,124,684 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,124,684 / (2.5 + 0.5 + 4 + 17.86) = 85,466 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2550 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 2550 K, but somewhat under it because of the higher specific heats of CO₂ and H₂O.

At 2350 K:

$$2.5\bar{h}_{\text{CO}_2} + 0.5\bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 17.86\bar{h}_{\text{N}_2} = (2.5)(122,091) + (0.5)(78,178) + (4)(100,846) + (17.86)(77,496) \\ = 2,131,779 \text{ kJ} \text{ (Higher than 2,124,684 kJ)}$$

At 2300 K:

$$2.5\bar{h}_{\text{CO}_2} + 0.5\bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 17.86\bar{h}_{\text{N}_2} = (2.5)(119,035) + (0.5)(76,345) + (4)(98,199) + (17.86)(75,676) \\ = 2,080,129 \text{ kJ} \text{ (Lower than 2,124,684 kJ)}$$

By interpolation, $T_P = \mathbf{2343 \text{ K}}$

15-108 The highest possible temperatures that can be obtained when liquid gasoline is burned steadily with air and with pure oxygen are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis The highest possible temperature that can be achieved during a combustion process is the temperature which occurs when a fuel is burned completely with stoichiometric amount of air in an adiabatic combustion chamber. It is determined from

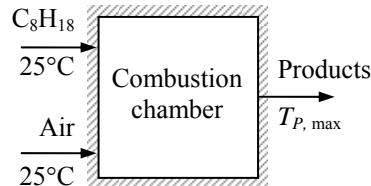

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h}_T - \bar{h}^\circ)_P = (N\bar{h}_f^\circ)_{C_8H_{18}}$$

since all the reactants are at the standard reference temperature of 25°C, and for O₂ and N₂. The theoretical combustion equation of C₈H₁₈ air is

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
C ₈ H ₁₈ (l)	-249,950	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO ₂	-393,520	9364

Thus,

$$(8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) + (47)(0 + \bar{h}_{N_2} - 8669) = (1)(-249,950)$$

$$\text{It yields } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} = 5,646,081 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $5,646,081/(8 + 9 + 47) = 88,220 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2650 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 2650 K, but somewhat under it because of the higher specific heat of H₂O.

$$\begin{aligned} \text{At 2400 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} &= (8)(125,152) + (9)(103,508) + (47)(79,320) \\ &= 5,660,828 \text{ kJ (Higher than 5,646,081 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At 2350 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} &= (8)(122,091) + (9)(100,846) + (47)(77,496) \\ &= 5,526,654 \text{ kJ (Lower than 5,646,081 kJ)} \end{aligned}$$

By interpolation, $T_P = 2395 \text{ K}$

If the fuel is burned with stoichiometric amount of pure O₂, the combustion equation would be

$$\text{Thus, } (8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) = (1)(-249,950)$$

$$\text{It yields } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = 5,238,638 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $5,238,638/(8 + 9) = 308,155 \text{ kJ/kmol}$. This enthalpy value is higher than the highest enthalpy value listed for H₂O and CO₂. Thus an estimate of the adiabatic flame temperature can be obtained by extrapolation.

$$\text{At 3200 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = (8)(174,695) + (9)(147,457) = 2,724,673 \text{ kJ}$$

$$\text{At 3250 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = (8)(177,822) + (9)(150,272) = 2,775,024 \text{ kJ}$$

By extrapolation, we get $T_P = 3597 \text{ K}$. However, the solution of this problem using EES gives **5645 K**. The large difference between these two values is due to extrapolation.

15-109 Methyl alcohol vapor is burned with the stoichiometric amount of air in a combustion chamber. The maximum pressure that can occur in the combustion chamber if the combustion takes place at constant volume and the maximum volume of the combustion chamber if the combustion occurs at constant pressure are to be determined.

Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

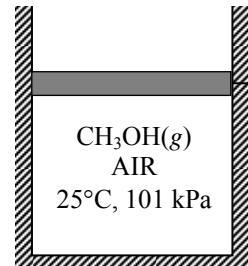

Analysis (a) The combustion equation of $\text{CH}_3\text{OH}(g)$ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1 + 2a_{\text{th}} = 2 + 2 \longrightarrow a_{\text{th}} = 1.5$$

Thus,

The final temperature in the tank is determined from the energy balance relation $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for reacting closed systems under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$),

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Assuming both the reactants and the products to behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_p} - \bar{h}_{298K} - R_u T)_P = \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
CH_3OH	-200,670	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$(1)(-\bar{h}_{\text{CO}_2} - 393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_p) + (2)(-\bar{h}_{\text{H}_2\text{O}} - 241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_p) + (5.64)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_p) = (1)(-200,670 - 8.314 \times 298) + (1.5)(0 - 8.314 \times 298) + (5.64)(0 - 8.314 \times 298)$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} - 71.833 \times T_p = 734,388 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

At 2850 K:

$$\begin{aligned} \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} - 71.833 \times T_p &= (1)(152,908) + (2)(127,952) + (5.64)(95,859) - (71.833)(2850) \\ &= 744,733 \text{ kJ} \text{ (Higher than } 734,388 \text{ kJ)} \end{aligned}$$

At 2800 K:

$$\begin{aligned} \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} - 71.833 \times T_p &= (1)(149,808) + (2)(125,198) + (5.64)(94,014) - (71.833)(2800) \\ &= 729,311 \text{ kJ} \text{ (Lower than } 734,388 \text{ kJ)} \end{aligned}$$

By interpolation $T_P = 2816 \text{ K}$

Since both the reactants and the products behave as ideal gases, the final (maximum) pressure that can occur in the combustion chamber is determined to be

$$\frac{P_1 V}{P_2 V} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(8.64 \text{ kmol})(2816 \text{ K})}{(8.14 \text{ kmol})(298 \text{ K})} (101 \text{ kPa}) = 1013 \text{ kPa}$$

(b) The combustion equation of $\text{CH}_3\text{OH}(g)$ remains the same in the case of constant pressure. Further, the boundary work in this case can be combined with the u terms so that the first law relation can be expressed in terms of enthalpies just like the steady-flow process,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Since both the reactants and the products behave as ideal gases, we have $h = h(T)$. Also noting that $Q = 0$ for an adiabatic combustion process, the 1st law relation reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_p} - \bar{h}_{298 \text{ K}})_P = \sum N_R (\bar{h}_f^\circ)_R$$

since the reactants are at the standard reference temperature of 25°C . Then using data from the mini table above, we get

$$\begin{aligned} (1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (5.64)(0 + \bar{h}_{\text{N}_2} - 8669) \\ = (1)(-200,670) + (1.5)(0) + (5.64)(0) \end{aligned}$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} = 754,555 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

$$\begin{aligned} \text{At } 2350 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} &= (1)(122,091) + (2)(100,846) + (5.64)(77,496) \\ &= 760,860 \text{ kJ } (\text{Higher than } 754,555 \text{ kJ}) \end{aligned}$$

$$\begin{aligned} \text{At } 2300 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 5.64\bar{h}_{\text{N}_2} &= (1)(119,035) + (2)(98,199) + (5.64)(75,676) \\ &= 742,246 \text{ kJ } (\text{Lower than } 754,555 \text{ kJ}) \end{aligned}$$

By interpolation, $T_P = 2333 \text{ K}$

Treating both the reactants and the products as ideal gases, the final (maximum) volume that the combustion chamber can have is determined to be

$$\frac{P V_1}{P V_2} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow V_2 = \frac{N_2 T_2}{N_1 T_1} V_1 = \frac{(8.64 \text{ kmol})(2333 \text{ K})}{(8.14 \text{ kmol})(298 \text{ K})} (1.5 \text{ L}) = 12.5 \text{ L}$$

15-110 Problem 15–109 is reconsidered. The effect of the initial volume of the combustion chamber on the maximum pressure of the chamber for constant volume combustion or the maximum volume of the chamber for constant pressure combustion is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

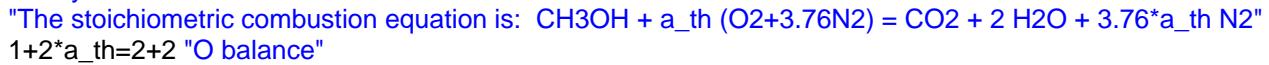

"Given"

$$\begin{aligned}V_1 &= 1.5 \text{ [L]} \\T_1 &= (25+273) \text{ [K]} \\P_1 &= 101 \text{ [kPa]} \\T_0 &= 25+273 \text{ [K]}\end{aligned}$$

"Properties"

$$R_u = 8.314 \text{ "[kJ/kmol-K]"}$$

15-111 Methane is burned with the stoichiometric amount of air in a combustion chamber. The maximum pressure that can occur in the combustion chamber if the combustion takes place at constant volume and the maximum volume of the combustion chamber if the combustion occurs at constant pressure are to be determined.

Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

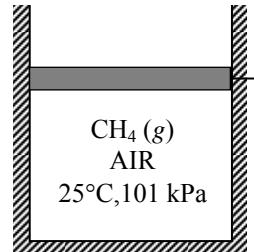

Analysis (a) The combustion equation of $\text{CH}_4(g)$ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

Thus,

The final temperature in the tank is determined from the energy balance relation $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for reacting closed systems under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$),

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_p} - \bar{h}_{298\text{K}} - R_u T)_P = \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C . From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
CH_4	-74,850	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$(1)(-\bar{h}_{\text{CO}_2} - 393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_p) + (2)(-\bar{h}_{\text{H}_2\text{O}} - 241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_p) + (7.52)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_p) = (1)(-74,850 - 8.314 \times 298) + (2)(0 - 8.314 \times 298) + (7.52)(0 - 8.314 \times 298)$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} - 87.463 \times T_p = 870,609 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

At 2850 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} - 87.463 \times T_p = (1)(152,908) + (2)(127,952) + (7.52)(95,859) - (87.463)(2850) = 880,402 \text{ kJ} \text{ (Higher than 870,609 kJ)}$$

At 2800 K:

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} - 87.463 \times T_p = (1)(149,808) + (2)(125,198) + (7.52)(94,014) - (87.463)(2800) = 862,293 \text{ kJ} \text{ (Lower than 870,609 kJ)}$$

By interpolation, $T_P = 2823 \text{ K}$

Treating both the reactants and the products as ideal gases, the final (maximum) pressure that can occur in the combustion chamber is determined to be

$$\frac{P_1 V}{P_2 V} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(10.52 \text{ kmol})(2823 \text{ K})}{(10.52 \text{ kmol})(298 \text{ K})} (101 \text{ kPa}) = 957 \text{ kPa}$$

(b) The combustion equation of $\text{CH}_4(g)$ remains the same in the case of constant pressure. Further, the boundary work in this case can be combined with the u terms so that the first law relation can be expressed in terms of enthalpies just like the steady-flow process,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Again since both the reactants and the products behave as ideal gases, we have $h = h(T)$. Also noting that $Q = 0$ for an adiabatic combustion process, the energy balance relation reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_p} - \bar{h}_{298 \text{ K}})_P = \sum N_R (\bar{h}_f^\circ)_R$$

since the reactants are at the standard reference temperature of 25°C . Then using data from the mini table above, we get

$$\begin{aligned} (1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (7.52)(0 + \bar{h}_{\text{N}_2} - 8669) \\ = (1)(-74,850) + (2)(0) + (7.52)(0) \end{aligned}$$

It yields

$$\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} = 896,673 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

$$\begin{aligned} \text{At } 2350 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} &= (1)(122,091) + (2)(100,846) + (7.52)(77,496) \\ &= 906,553 \text{ kJ } (\text{Higher than } 896,673 \text{ kJ}) \end{aligned}$$

$$\begin{aligned} \text{At } 2300 \text{ K: } \bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 7.52\bar{h}_{\text{N}_2} &= (1)(119,035) + (2)(98,199) + (7.52)(75,676) \\ &= 884,517 \text{ kJ } (\text{Lower than } 896,673 \text{ kJ}) \end{aligned}$$

By interpolation, $T_P = 2328 \text{ K}$

Treating both the reactants and the products as ideal gases, the final (maximum) volume that the combustion chamber can have is determined to be

$$\frac{P V_1}{P V_2} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow V_2 = \frac{N_2 T_2}{N_1 T_1} V_1 = \frac{(10.52 \text{ kmol})(2328 \text{ K})}{(10.52 \text{ kmol})(298 \text{ K})} (1.5 \text{ L}) = 11.7 \text{ L}$$

15-112 n-Octane is burned with 100 percent excess air. The combustion is incomplete. The maximum work that can be produced is to be determined.

Assumptions 1 Combustion is incomplete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The combustion equation with 100% excess air and 10% CO is

The coefficient for O₂ is determined from its mass balance as

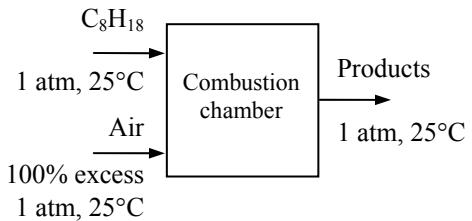

$$25 = 7.2 + 0.4 + 4.5 + x \longrightarrow x = 12.9$$

Substituting,

The reactants and products are at 25°C and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(16,530) - (7.2)(-394,360) - (0.8)(-137,150) - (9)(-228,590) \\ &= 5,022,952 \text{ kJ (per kmol of fuel)} \end{aligned}$$

since the \bar{g}_f° of stable elements at 25°C and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{5,022,952 \text{ kJ/kmol}}{114 \text{ kg/kmol}} = \mathbf{44,060 \text{ kJ/kg fuel}}$$

15-113E Methane is burned with stoichiometric air. The maximum work that can be produced is to be determined.

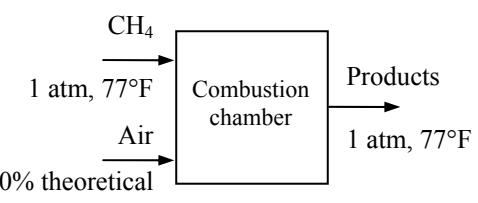

Assumptions 1 Combustion is incomplete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The combustion equation is

The reactants and products are at 77°F and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(-21,860) - (1)(-169,680) - (2)(-98,350) \\ &= 344,520 \text{ Btu (per lbmol of fuel)} \end{aligned}$$

since the \bar{g}_f° of stable elements at 77°F and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{344,520 \text{ Btu/lbmol}}{16 \text{ lbmol/lbmol}} = \mathbf{21,530 \text{ Btu/lbm fuel}}$$

15-114E Methane is burned with 100% excess air. The maximum work that can be produced is to be determined and compared to when methane is burned with stoichiometric air.

Assumptions 1 Combustion is incomplete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The combustion equation with 100% excess air is

The reactants and products are at 77°F and 1 atm, which is the standard reference state and also the state of the surroundings.

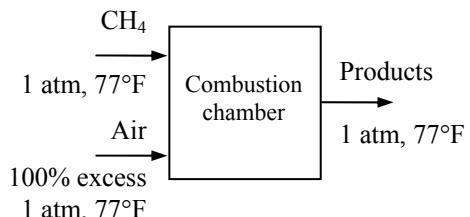

Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(-21,860) - (1)(-169,680) - (2)(-98,350) \\ &= 344,520 \text{ Btu (per lbmol of fuel)} \end{aligned}$$

since the \bar{g}_f° of stable elements at 77°F and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{344,52 \text{ Btu/lbmol}}{16 \text{ lbm/lbmol}} = \mathbf{21,530 \text{ Btu/lbm fuel}}$$

The excess air only adds oxygen and nitrogen to the reactants and products. The excess air then does not change the maximum work.

15-115 Methane is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of CH₄ and air are 16 kg/kmol and 29 kg/kmol, respectively (Table A-1).

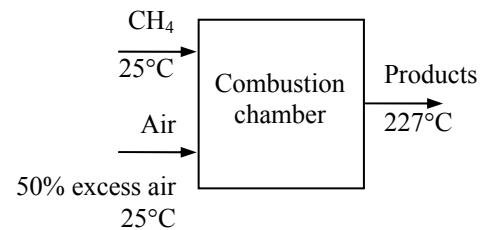

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol CH₄, the combustion equation can be written as

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{500\text{K}}$ kJ/kmol
CH ₄	-74,850	---	---
O ₂	0	8682	14,770
N ₂	0	8669	14,581
H ₂ O (g)	-241,820	9904	16,828
CO ₂	-393,520	9364	17,678

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 17,678 - 9364) + (2)(-241,820 + 16,828 - 9904) \\ &\quad + (1)(0 + 14,770 - 8682) + (11.28)(0 + 14,581 - 8669) - (1)(-74,850) \\ &= -707,373 \text{ kJ/kmol of fuel} \end{aligned}$$

The heat loss per unit mass of the fuel is

$$Q_{\text{out}} = \frac{707,373 \text{ kJ/kmol of fuel}}{16 \text{ kg/kmol of fuel}} = 44,211 \text{ kJ/kg fuel}$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$\frac{m_s}{m_f} = \frac{Q_{\text{out}}}{\Delta h_s} = \frac{44,211 \text{ kJ/kg fuel}}{(3214.5 - 852.26) \text{ kJ/kg steam}} = 18.72 \text{ kg steam/kg fuel}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
CH ₄	1	---	186.16	0	186.16
O ₂	3	0.21	205.04	-12.98	654.06
N ₂	11.28	0.79	191.61	-1.960	2183.47
					$S_R = 3023.69 \text{ kJ/K}$
CO ₂	1	0.0654	234.814	-22.67	257.48
H ₂ O (g)	2	0.1309	206.413	-16.91	446.65
O ₂	1	0.0654	220.589	-22.67	243.26
N ₂	11.28	0.7382	206.630	-2.524	2359.26
					$S_P = 3306.65 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 3306.65 - 3023.69 + \frac{707,373}{298} = 2657 \text{ kJ/K (per kmol fuel)}$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$\Delta X_{\text{gases}} = -X_{\text{dest}} = -T_0 S_{\text{gen}} = -(298 \text{ K})(2657 \text{ kJ/K}) = -791,786 \text{ kJ/kmol fuel}$$

Per unit mass basis,

$$\Delta X_{\text{gases}} = \frac{-791,786 \text{ kJ/kmol fuel}}{16 \text{ kg/kmol}} = \mathbf{-49,490 \text{ kJ/kg fuel}}$$

Note that the exergy change is negative since the exergy of combustion gases decreases.

(c) The exergy change of the steam stream is

$$\Delta X_{\text{steam}} = \Delta h - T_0 \Delta s = (3214.5 - 852.26) - (298)(6.7714 - 2.3305) = \mathbf{1039 \text{ kJ/kg steam}}$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$\begin{aligned} X_{\text{dest}} &= -\left(\frac{m_s}{m_f} \Delta X_{\text{steam}} + \Delta X_{\text{gases}} \right) \\ &= -[(18.72 \text{ kg steam/kg fuel})(1039 \text{ kJ/kg steam}) + (-49,490 \text{ kJ/kg fuel})] \\ &= \mathbf{30,040 \text{ kJ/kg fuel}} \end{aligned}$$

15-116 A coal from Utah is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible. 5 The effect of sulfur on the energy and entropy balances is negligible.

Properties The molar masses of C, H₂, N₂, O₂, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{61.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.117 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.79 \text{ kg}}{2 \text{ kg/kmol}} = 2.895 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{25.31 \text{ kg}}{32 \text{ kg/kmol}} = 0.7909 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1.09 \text{ kg}}{28 \text{ kg/kmol}} = 0.03893 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{1.41 \text{ kg}}{32 \text{ kg/kmol}} = 0.04406 \text{ kmol}$$

61.40% C
5.79% H ₂
25.31% O ₂
1.09% N ₂
1.41% S
5.00% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.117 + 2.895 + 0.7909 + 0.03893 + 0.04406 = 8.886 \text{ kmol}$$

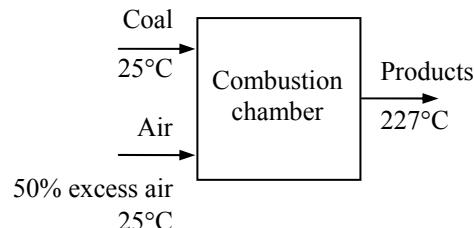

$$y_C = \frac{N_C}{N_m} = \frac{5.117 \text{ kmol}}{8.886 \text{ kmol}} = 0.5758$$

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.895 \text{ kmol}}{8.886 \text{ kmol}} = 0.3258$$

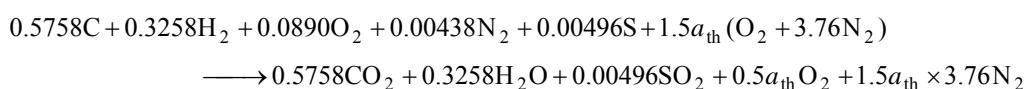

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.7909 \text{ kmol}}{8.886 \text{ kmol}} = 0.0890$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.03893 \text{ kmol}}{8.886 \text{ kmol}} = 0.00438$$

$$y_S = \frac{N_S}{N_m} = \frac{0.04406 \text{ kmol}}{8.886 \text{ kmol}} = 0.00496$$

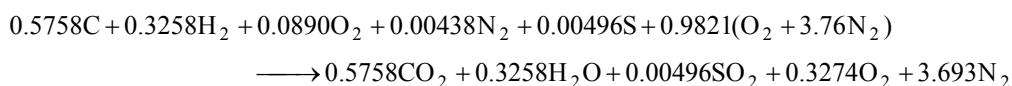

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the oxygen balance,

$$O_2 \text{ balance: } 0.0890 + 1.5a_{th} = 0.5758 + 0.5 \times 0.3258 + 0.00496 + 0.5a_{th} \longrightarrow a_{th} = 0.6547$$

Substituting,

The apparent molecular weight of the coal is

$$\begin{aligned}
 M_m &= \frac{m_m}{N_m} = \frac{(0.5758 \times 12 + 0.3258 \times 2 + 0.0890 \times 32 + 0.00438 \times 28 + 0.00496 \times 32) \text{ kg}}{(0.5758 + 0.3258 + 0.0890 + 0.00438 + 0.00496) \text{ kmol}} \\
 &= \frac{10.69 \text{ kg}}{1.0 \text{ kmol}} = 10.69 \text{ kg/kmol coal}
 \end{aligned}$$

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	\bar{h}_{298K} kJ/kmol	\bar{h}_{500K} kJ/kmol
O ₂	0	8682	14,770
N ₂	0	8669	14,581
H ₂ O (g)	-241,820	9904	16,828
CO ₂	-393,520	9364	17,678

Thus,

$$\begin{aligned}
 -Q_{\text{out}} &= (0.5758)(-393,520 + 17,678 - 9364) + (0.3258)(-241,820 + 16,828 - 9904) \\
 &\quad + (0.3274)(0 + 14,770 - 8682) + (3.693)(0 + 14,581 - 8669) - 0 \\
 &= -274,505 \text{ kJ/kmol of fuel}
 \end{aligned}$$

The heat loss per unit mass of the fuel is

$$Q_{\text{out}} = \frac{274,505 \text{ kJ/kmol of fuel}}{10.69 \text{ kg/kmol of fuel}} = 25,679 \text{ kJ/kg fuel}$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$\frac{m_s}{m_f} = \frac{Q_{\text{out}}}{\Delta h_s} = \frac{25,679 \text{ kJ/kg fuel}}{(3214.5 - 852.26) \text{ kJ/kg steam}} = \mathbf{10.87 \text{ kg steam/kg fuel}}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C	0.5758	0.5758	5.74	-4.589	5.95
H ₂	0.3258	0.3258	130.68	-9.324	45.61
O ₂	0.0890	0.0890	205.04	-20.11	20.04
N ₂	0.00438	0.00438	191.61	-45.15	1.04
O ₂	0.9821	0.21	205.04	-12.98	214.12
N ₂	3.693	0.79	191.61	-1.960	714.85
					$S_R = 1001.61 \text{ kJ/K}$
CO ₂	0.5758	0.1170	234.814	-17.84	145.48
H ₂ O (g)	0.3258	0.0662	206.413	-22.57	74.60
O ₂	0.3274	0.0665	220.589	-22.54	79.60
N ₂	3.693	0.7503	206.630	-2.388	771.90
					$S_P = 1071.58 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 1071.58 - 1001.61 + \frac{274,505}{298} = 991.1 \text{ kJ/K (per kmol fuel)}$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$\Delta X_{\text{gases}} = -X_{\text{dest}} = -T_0 S_{\text{gen}} = -(298 \text{ K})(991.1 \text{ kJ/K}) = -295,348 \text{ kJ/kmol fuel}$$

Per unit mass basis,

$$\Delta X_{\text{gases}} = \frac{-295,348 \text{ kJ/K}}{10.69 \text{ kg/kmol}} = \mathbf{-27,630 \text{ kJ/kg fuel}}$$

Note that the exergy change is negative since the exergy of combustion gases decreases.

(c) The exergy change of the steam stream is

$$\Delta X_{\text{steam}} = \Delta h - T_0 \Delta s = (3214.5 - 852.26) - (298)(6.7714 - 2.3305) = \mathbf{1039 \text{ kJ/kg steam}}$$

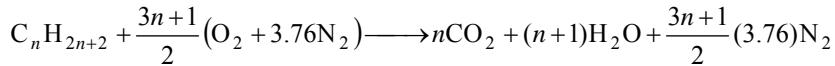

(d) The lost work potential is the negative of the net exergy change of both streams:

$$\begin{aligned} X_{\text{dest}} &= -\left(\frac{m_s}{m_f} \Delta X_{\text{steam}} + \Delta X_{\text{gases}} \right) \\ &= -[(10.87 \text{ kg steam/kg fuel})(1039 \text{ kJ/kg steam}) + (-27,630 \text{ kJ/kg fuel})] \\ &= \mathbf{16,340 \text{ kJ/kg fuel}} \end{aligned}$$

15-117 An expression for the HHV of a gaseous alkane C_nH_{2n+2} in terms of n is to be developed.

Assumptions **1** Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 . **3** Combustion gases are ideal gases.

Analysis The complete reaction balance for 1 kmol of fuel is

Both the reactants and the products are taken to be at the standard reference state of $25^\circ C$ and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that N_2 and O_2 are stable elements, and thus their enthalpy of formation is zero. Then,

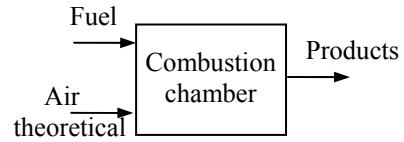

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P} - \sum N_R \bar{h}_{f,R} = (N\bar{h}_f)_{CO_2} + (N\bar{h}_f)_{H_2O} - (N\bar{h}_f)_{fuel}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$h_C = n(-393,520) + (n+1)(-285,830) - (\bar{h}_f)_{fuel}$$

The HHV of the fuel is

$$HHV = \frac{-h_C}{M_{fuel}} = \frac{n(-393,520) + (n+1)(-285,830) - (\bar{h}_f)_{fuel}}{M_{fuel}}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$LHV = \frac{n(-393,520) + (n+1)(-241,820) - (\bar{h}_f)_{fuel}}{M_{fuel}}$$

15-118 It is to be shown that the work output of the Carnot engine will be maximum when $T_p = \sqrt{T_0 T_{af}}$. It is also to be

shown that the maximum work output of the Carnot engine in this case becomes $w = CT_{af} \left(1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}}\right)^2$.

Analysis The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature T_{af} since the chamber is adiabatic and the fuel is burned completely. The combustion gases experience no change in their chemical composition as they flow through the heat exchanger. Therefore, we can treat the combustion gases as a gas stream with a constant specific heat c_p . Noting that the heat exchanger involves no work interactions, the energy balance equation for this single-stream steady-flow device can be written as

$$\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C(T_p - T_{af})$$

where \dot{Q} is the negative of the heat supplied to the heat engine. That is,

$$\dot{Q}_H = -\dot{Q} = \dot{m}C(T_{af} - T_p)$$

Then the work output of the Carnot heat engine can be expressed as

$$\dot{W} = \dot{Q}_H \left(1 - \frac{T_0}{T_p}\right) = \dot{m}C(T_{af} - T_p) \left(1 - \frac{T_0}{T_p}\right) \quad (1)$$

Taking the partial derivative of \dot{W} with respect to T_p while holding T_{af} and T_0 constant gives

$$\frac{\partial \dot{W}}{\partial T_p} = 0 \longrightarrow -\dot{m}C \left(1 - \frac{T_0}{T_p}\right) + \dot{m}C(T_p - T_{af}) \frac{T_0}{T_p^2} = 0$$

Solving for T_p we obtain

$$T_p = \sqrt{T_0 T_{af}}$$

which is the temperature at which the work output of the Carnot engine will be a maximum. The maximum work output is determined by substituting the relation above into Eq. (1),

$$\dot{W} = \dot{m}C(T_{af} - T_p) \left(1 - \frac{T_0}{T_p}\right) = \dot{m}C(T_{af} - \sqrt{T_0 T_{af}}) \left(1 - \frac{T_0}{\sqrt{T_0 T_{af}}}\right)$$

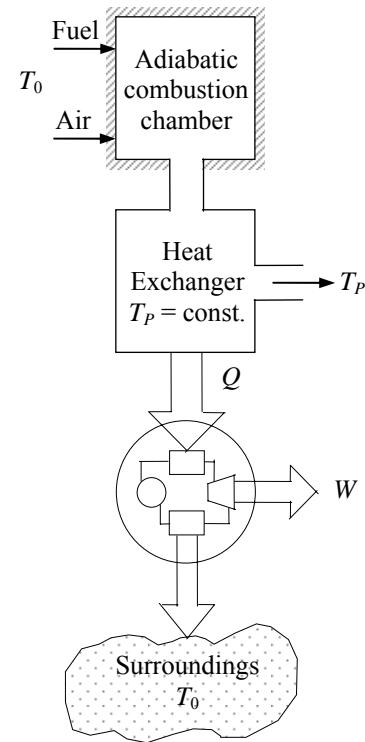

It simplifies to

$$\dot{W} = \dot{m}CT_{af} \left(1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}}\right)^2$$

or

$$w = CT_{af} \left(1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}}\right)^2$$

which is the desired relation.

15-119 It is to be shown that the work output of the reversible heat engine operating at the specified conditions is

$$\dot{W}_{\text{rev}} = \dot{m}CT_0 \left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0} \right). \quad \text{It is also to be shown that the effective flame temperature } T_e \text{ of the furnace considered is}$$

$$T_e = \frac{T_{\text{af}} - T_0}{\ln(T_{\text{af}}/T_0)}.$$

Analysis The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature T_{af} since the chamber is adiabatic and the fuel is burned completely. The combustion gases experience no change in their chemical composition as they flow through the heat exchanger. Therefore, we can treat the combustion gases as a gas stream with a constant specific heat c_p . Also, the work output of the reversible heat engine is equal to the reversible work \dot{W}_{rev} of the heat exchanger as the combustion gases are cooled from T_{af} to T_0 . That is,

$$\begin{aligned}\dot{W}_{\text{rev}} &= \dot{m}(h_i - h_e - T_0(s_i - s_e)) \\ &= \dot{m}C \left(T_{\text{af}} - T_0 - T_0 \left(C \ln \frac{T_{\text{af}}}{T_0} - R \ln \frac{P_{\text{af}}^{\phi_0}}{P_0} \right) \right) \\ &= \dot{m}C \left(T_{\text{af}} - T_0 - T_0 C \ln \frac{T_{\text{af}}}{T_0} \right)\end{aligned}$$

which can be rearranged as

$$\dot{W}_{\text{rev}} = \dot{m}CT_0 \left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0} \right) \quad \text{or} \quad w_{\text{rev}} = CT_0 \left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0} \right) \quad (1)$$

which is the desired result.

The effective flame temperature T_e can be determined from the requirement that a Carnot heat engine which receives the same amount of heat from a heat reservoir at constant temperature T_e produces the same amount of work. The amount of heat delivered to the heat engine above is

$$\dot{Q}_H = \dot{m}(h_i - h_e) = \dot{m}C(T_{\text{af}} - T_0)$$

A Carnot heat engine which receives this much heat at a constant temperature T_e will produce work in the amount of

$$\dot{W} = \dot{Q}_H \eta_{\text{th,Carnot}} = \dot{m}C(T_{\text{af}} - T_0) \left(1 - \frac{T_0}{T_e} \right) \quad (2)$$

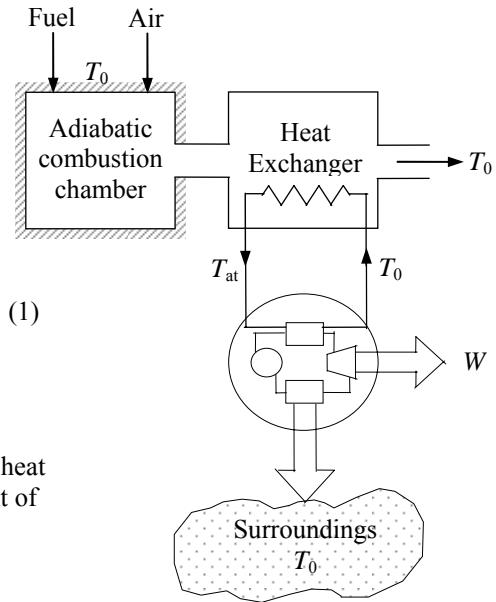

Setting equations (1) and (2) equal to each other yields

$$\begin{aligned}\dot{m}CT_0 \left(\frac{T_{\text{af}}}{T_0} - 1 - \ln \frac{T_{\text{af}}}{T_0} \right) &= \dot{m}C(T_{\text{af}} - T_0) \left(1 - \frac{T_0}{T_e} \right) \\ T_{\text{af}} - T_0 - T_0 \ln \frac{T_{\text{af}}}{T_0} &= T_{\text{af}} - T_{\text{af}} \frac{T_0}{T_e} - T_0 + T_0 \frac{T_0}{T_e}\end{aligned}$$

Simplifying and solving for T_e , we obtain

$$T_e = \frac{T_{\text{af}} - T_0}{\ln(T_{\text{af}}/T_0)}$$

which is the desired relation.

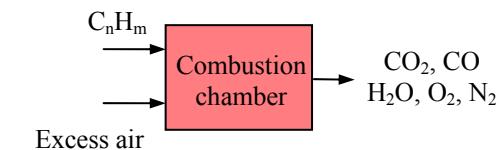

15-120 The combustion of a hydrocarbon fuel C_nH_m with excess air and incomplete combustion is considered. The coefficients of the reactants and products are to be written in terms of other parameters.

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient A_{th} is determined from an O_2 balance:

$$A_{th} = n + m/4$$

The reaction with excess air and incomplete combustion is

The given reaction is

Thus,

$$D = an$$

$$E = bn$$

$$F = m/2$$

$$J = 3.76(1+B)A_{th}$$

The coefficient G for O_2 is determined from a mass balance,

O_2 balance:

$$\begin{aligned} (1+B)A_{th} &= an + \frac{bn}{2} + \frac{m}{4} + G \\ (1+B)\left(n + \frac{m}{4}\right) &= an + \frac{bn}{2} + \frac{m}{4} + G \\ \left(n + \frac{m}{4}\right) + BA_{th} &= an + \frac{bn}{2} + \frac{m}{4} + G \\ G &= n + BA_{th} - an - \frac{bn}{2} \\ &= n(1-a) + BA_{th} - \frac{bn}{2} \\ &= nb - \frac{bn}{2} + BA_{th} \\ &= \frac{bn}{2} + BA_{th} \end{aligned}$$

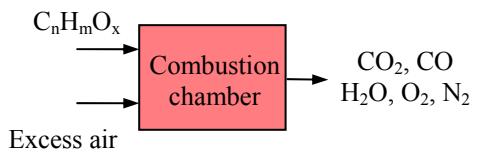

15-121 The combustion of an alcohol fuel ($C_nH_mO_x$) with excess air and incomplete combustion is considered. The coefficients of the reactants and products are to be written in terms of other parameters.

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient A_{th} is determined from an O_2 balance:

$$x/2 + A_{th} = n + m/4 \longrightarrow A_{th} = n + m/4 - x/2$$

The reaction with excess air and incomplete combustion is

The given reaction is

Thus,

$$D = a n$$

$$E = b n$$

$$F = m/2$$

$$J = 3.76(1+B)A_{th}$$

The coefficient G for O_2 is determined from a mass balance,

O_2 balance:

$$\begin{aligned} \frac{x}{2} + (1+B)A_{th} &= a n + \frac{bn}{2} + \frac{m}{4} + G \\ \frac{x}{2} + (1+B)\left(n + \frac{m}{4} - \frac{x}{2}\right) &= a n + \frac{bn}{2} + \frac{m}{4} + G \\ \frac{x}{2} + \left(n + \frac{m}{4} - \frac{x}{2}\right) + B\left(n + \frac{m}{4} - \frac{x}{2}\right) &= a n + \frac{bn}{2} + \frac{m}{4} + G \\ \frac{x}{2} + \left(n + \frac{m}{4} - \frac{x}{2}\right) + BA_{th} &= a n + \frac{bn}{2} + \frac{m}{4} + G \\ G &= n - a n + BA_{th} - \frac{bn}{2} \\ &= n(1-a) - \frac{bn}{2} + BA_{th} \\ &= nb - \frac{bn}{2} + BA_{th} \\ &= \frac{bn}{2} + BA_{th} \end{aligned}$$

15-122 The combustion of a mixture of an alcohol fuel ($C_nH_mO_x$) and a hydrocarbon fuel (C_wH_z) with excess air and incomplete combustion is considered. The coefficients of the reactants and products are to be written in terms of other parameters.

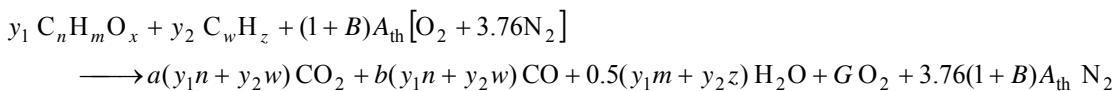

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient A_{th} is determined from an O_2 balance:

$$y_1x/2 + A_{th} = (y_1n + y_2w) + (y_1m + y_2z)/4 \longrightarrow A_{th} = (y_1n + y_2w) + (y_1m + y_2z)/4 - y_1x/2$$

The reaction with excess air and incomplete combustion is

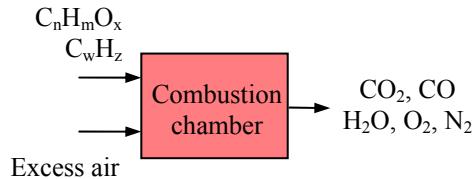

The given reaction is

Thus,

$$\begin{aligned} D &= a(y_1n + y_2w) \\ E &= b(y_1n + y_2w) \\ F &= 0.5(y_1m + y_2z) \\ J &= 3.76(1+B)A_{th} \end{aligned}$$

The coefficient G for O_2 is determined from a mass balance,

O_2 balance:

$$\begin{aligned} 0.5y_1x + (1+B)A_{th} &= a(y_1n + y_2w) + 0.5b(y_1n + y_2w) + 0.25(y_1m + y_2z) + G \\ 0.5y_1x + (y_1n + y_2w) + 0.25(y_1m + y_2z) - 0.5y_1x + BA_{th} &= a(y_1n + y_2w) + 0.5b(y_1n + y_2w) + 0.25(y_1m + y_2z) + G \\ G &= (y_1n + y_2w) - a(y_1n + y_2w) - 0.5b(y_1n + y_2w) + BA_{th} \\ &= (y_1n + y_2w)(1-a) - 0.5b(y_1n + y_2w) + BA_{th} \\ &= b(y_1n + y_2w) - 0.5b(y_1n + y_2w) + BA_{th} \\ &= 0.5b(y_1n + y_2w) + BA_{th} \end{aligned}$$

15-123 The effect of the amount of air on the adiabatic flame temperature of liquid octane (C_8H_{18}) is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air} :

Reaction: $CxHyOz + (y/4 + x-z/2) (\text{Theo_air}/100) (O_2 + 3.76 N_2)$

$\leftrightarrow xCO_2 + (y/2) H_2O + 3.76 (y/4 + x-z/2) (\text{Theo_air}/100) N_2 + (y/4 + x-z/2) (\text{Theo_air}/100 - 1) O_2$

"For theoretical oxygen, the complete combustion equation for CH_3OH is"

" $CH_3OH + A_{th} O_2 = CO_2 + 2 H_2O$ "

" $1 + 2 * A_{th} = 1 * 2 + 2 * 1$ " "theoretical O balance"

Adiabatic, Incomplete Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air} :

15-124 A general program is to be written to determine the adiabatic flame temperature during the complete combustion of a hydrocarbon fuel C_nH_m at $25^\circ C$ in a steady-flow combustion chamber when the percent of excess air and its temperature are specified.

Analysis The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air} :

Reaction: $CxHyOz + (y/4 + x-z/2) (\text{Theo_air}/100) (O_2 + 3.76 N_2)$

$\leftrightarrow xCO_2 + (y/2) H_2O + 3.76 (y/4 + x-z/2) (\text{Theo_air}/100) N_2 + (y/4 + x-z/2) (\text{Theo_air}/100 - 1) O_2$ "

"For theoretical oxygen, the complete combustion equation for CH_3OH is"

" $CH_3OH + A_{th} O_2 = CO_2 + 2 H_2O$ "

" $1 + 2*A_{th} = 1^*2 + 2^*1$ " theoretical O balance"

Adiabatic, Incomplete Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air} :

Reaction: $CxHyOz + (y/4 + x-z/2) (\text{Theo_air}/100) (O_2 + 3.76 N_2)$

$\leftrightarrow (x-w)CO_2 + wCO + (y/2) H_2O + 3.76 (y/4 + x-z/2) (\text{Theo_air}/100) N_2 + ((y/4 + x-z/2)$

$(\text{Theo_air}/100 - 1) + w/2 O_2$ "

" T_{prod} is the adiabatic combustion temperature, assuming no dissociation.

Theo_air is the % theoretical air."

"The initial guess value of T_{prod} = 450K ."

Fundamentals of Engineering (FE) Exam Problems

15-129 A fuel is burned with 70 percent theoretical air. This is equivalent to

- (a) 30% excess air
- (b) 70% excess air
- (c) 30% deficiency of air
- (d) 70% deficiency of air
- (e) stoichiometric amount of air

Answer (c) 30% deficiency of air

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
air_th=0.7
"air_th=air_access+1"
air_th=1-air_deficiency
```

15-130 Propane C₃H₈ is burned with 150 percent theoretical air. The air-fuel mass ratio for this combustion process is

- (a) 5.3
- (b) 10.5
- (c) 15.7
- (d) 23.4
- (e) 39.3

Answer (d) 23.4

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
n_C=3

W1_AF=1/AF "Taking the inverse of AF"
 W2_AF=n_O2+n_N2 "Finding air-fuel mole ratio"
 W3_AF=AF/coeff "Ignoring excess air"

15-132 A fuel is burned steadily in a combustion chamber. The combustion temperature will be the highest except when

- (a) the fuel is preheated.
- (b) the fuel is burned with a deficiency of air.
- (c) the air is dry.
- (d) the combustion chamber is well insulated.
- (e) the combustion is complete.

Answer (b) the fuel is burned with a deficiency of air.

15-133 An equimolar mixture of carbon dioxide and water vapor at 1 atm and 60°C enter a dehumidifying section where the entire water vapor is condensed and removed from the mixture, and the carbon dioxide leaves at 1 atm and 60°C. The entropy change of carbon dioxide in the dehumidifying section is

- (a) -2.8 kJ/kg·K (b) -0.13 kJ/kg·K (c) 0 (d) 0.13 kJ/kg·K (e) 2.8 kJ/kg·K

Answer (b) -0.13 kJ/kg·K

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Cp_CO2=0.846
R_CO2=0.1889
T1=60+273 "K"
T2=T1
P1= 1 "atm"
P2=1 "atm"

```

"Some Wrong Solutions with Common Mistakes:"

W1_Q=LHV_CH4 "Assuming lower heating value"

W2_Q=EXCESS*hHV_CH4 "Assuming Q to be proportional to excess air"

15-135 The higher heating value of a hydrocarbon fuel C_nH_m with $m = 8$ is given to be 1560 MJ/kmol of fuel. Then its lower heating value is

- (a) 1384 MJ/kmol (b) 1208 MJ/kmol (c) 1402 MJ/kmol (d) 1540 MJ/kmol (e) 1550 MJ/kmol

Answer (a) 1384 MJ/kmol

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
HHV=1560 "MJ/kmol fuel"
h_fg=2.4423 "MJ/kg, Enthalpy of vaporization of water at 25C"
n_H=8
n_water=n_H/2
m_water=n_water*18
LHV=HHV-h_fg*m_water
```

"Some Wrong Solutions with Common Mistakes:"

W1_LHV=HHV - h_fg*n_water "Using mole numbers instead of mass"

W2_LHV= HHV - h_fg*m_water*2 "Taking mole numbers of H₂O to be m instead of m/2"

W3_LHV= HHV - h_fg*n_water*2 "Taking mole numbers of H₂O to be m instead of m/2, and using mole numbers"

15-136 Acetylene gas (C_2H_2) is burned completely during a steady-flow combustion process. The fuel and the air enter the combustion chamber at 25°C, and the products leave at 1500 K. If the enthalpy of the products relative to the standard reference state is -404 MJ/kmol of fuel, the heat transfer from the combustion chamber is

- (a) 177 MJ/kmol (b) 227 MJ/kmol (c) 404 MJ/kmol (d) 631 MJ/kmol (e) 751 MJ/kmol

Answer (d) 631 MJ/kmol

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
hf_fuel=226730/1000 "MJ/kmol fuel"

S_react-S_prod-Q_out/To+S_gen=0 "Entropy balance for steady state operation, Sin-Sout+Sgen=0"
X_dest=To*S_gen
```

"Some Wrong Solutions with Common Mistakes:"

W1_Xdest=S_gen "Taking Sgen as exergy destruction"
W2_Xdest=To*S_gen1; S_react-S_prod-S_gen1=0 "Ignoring Q_out/To"

15-139 ... 15-144 Design and Essay Problems

15-139 A certain industrial process generates a liquid solution of ethanol and water as the waste product. The solution is to be burned using methane. A combustion process is to be developed to accomplish this incineration process with minimum amount of methane.

Analysis The mass flow rate of the liquid ethanol-water solution is given to be 10 kg/s. Considering that the mass fraction of ethanol in the solution is 0.2,

$$\begin{aligned}\dot{m}_{\text{ethanol}} &= (0.2)(10 \text{ kg/s}) = 2 \text{ kg/s} \\ \dot{m}_{\text{water}} &= (0.8)(10 \text{ kg/s}) = 8 \text{ kg/s}\end{aligned}$$

Noting that the molar masses $M_{\text{ethanol}} = 46$ and $M_{\text{water}} = 18 \text{ kg/kmol}$ and that mole numbers $N = m/M$, the mole flow rates become

$$\begin{aligned}\dot{N}_{\text{ethanol}} &= \frac{\dot{m}_{\text{ethanol}}}{M_{\text{ethanol}}} = \frac{2 \text{ kg/s}}{46 \text{ kg/kmol}} = 0.04348 \text{ kmol/s} \\ \dot{N}_{\text{water}} &= \frac{\dot{m}_{\text{water}}}{M_{\text{water}}} = \frac{8 \text{ kg/s}}{18 \text{ kg/kmol}} = 0.44444 \text{ kmol/s}\end{aligned}$$

Note that

$$\frac{\dot{N}_{\text{water}}}{\dot{N}_{\text{ethanol}}} = \frac{0.44444}{0.04348} = 10.222 \text{ kmol H}_2\text{O/kmol C}_2\text{H}_5\text{OH}$$

That is, 10.222 moles of liquid water is present in the solution for each mole of ethanol.

Assuming complete combustion, the combustion equation of $\text{C}_2\text{H}_5\text{OH}(\ell)$ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1 + 2a_{\text{th}} = 4 + 3 \longrightarrow a_{\text{th}} = 3$$

Thus,

Noting that 10.222 kmol of liquid water accompanies each kmol of ethanol, the actual combustion equation can be written as

The heat transfer for this combustion process is determined from the steady-flow energy balance equation with $W = 0$,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. We assume all the reactants to enter the combustion chamber at the standard reference temperature of 25°C . Furthermore, we assume the products to leave the combustion chamber at 1400 K which is a little over the required temperature of 1100°C . From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1400\text{ K}}$ kJ/kmol
$\text{C}_2\text{H}_5\text{OH} (\ell)$	-277,690	---	---
CH_4	-74,850	---	---
O_2	0	8682	45,648
N_2	0	8669	43,605
$\text{H}_2\text{O} (g)$	-241,820	9904	53,351
$\text{H}_2\text{O} (\ell)$	-285,830	---	---
CO_2	-393,520	9364	65,271

Thus,

$$\begin{aligned} Q &= (2)(-393,520 + 65,271 - 9364) + (3)(-241,820 + 53,351 - 9904) \\ &\quad + (11.28)(0 + 43,605 - 8669) - (1)(-277,690) - 0 - 0 \\ &\quad + (10.222)(-241,820 + 53,351 - 9904) - (10.222)(-285,830) \\ &= 295,409 \text{ kJ/kmol of C}_2\text{H}_5\text{OH} \end{aligned}$$

The positive sign indicates that 295,409 kJ of heat must be supplied to the combustion chamber from another source (such as burning methane) to ensure that the combustion products will leave at the desired temperature of 1400 K. Then the rate of heat transfer required for a mole flow rate of 0.04348 kmol $\text{C}_2\text{H}_5\text{OH}/\text{s}$ CO becomes

$$\dot{Q} = \dot{N}Q = (0.04348 \text{ kmol/s})(295,409 \text{ kJ/kmol}) = 12,844 \text{ kJ/s}$$

Assuming complete combustion, the combustion equation of $\text{CH}_4(g)$ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

Thus,

$$a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ equation as shown above under the same assumptions and using the same mini table:

$$\begin{aligned} Q &= (1)(-393,520 + 65,271 - 9364) + (2)(-241,820 + 53,351 - 9904) \\ &\quad + (7.52)(0 + 43,605 - 8669) - (1)(-74,850) - 0 - 0 \\ &= -396,790 \text{ kJ/kmol of CH}_4 \end{aligned}$$

That is, 396,790 kJ of heat is supplied to the combustion chamber for each kmol of methane burned. To supply heat at the required rate of 12,844 kJ/s, we must burn methane at a rate of

$$\dot{N}_{\text{CH}_4} = \frac{\dot{Q}}{Q} = \frac{12,844 \text{ kJ/s}}{396,790 \text{ kJ/kmol}} = 0.03237 \text{ kmolCH}_4/\text{s}$$

or,

$$\dot{m}_{\text{CH}_4} = M_{\text{CH}_4} \dot{N}_{\text{CH}_4} = (16 \text{ kg/kmol})(0.03237 \text{ kmolCH}_4/\text{s}) = \mathbf{0.5179 \text{ kg/s}}$$

Therefore, we must supply methane to the combustion chamber at a minimum rate 0.5179 kg/s in order to maintain the temperature of the combustion chamber above 1400 K.

K_p and Equilibrium Composition of Ideal Gases

16-1C No, the wooden table is NOT in chemical equilibrium with the air. With proper catalyst, it will react with the oxygen in the air and burn.

16-2C They are

$$K_p = \frac{P_C^{v_C} P_D^{v_D}}{P_A^{v_A} P_B^{v_B}}, \quad K_p = e^{-\Delta G^*(T) / R_u T} \quad \text{and} \quad K_p = \frac{N_C^{v_C} N_D^{v_D}}{N_A^{v_A} N_B^{v_B}} \left(\frac{P}{N_{\text{total}}} \right)^{\Delta v}$$

where $\Delta v = v_C + v_D - v_A - v_B$. The first relation is useful in partial pressure calculations, the second in determining the K_p from gibbs functions, and the last one in equilibrium composition calculations.

16-3C (a) No, because K_p depends on temperature only.

(b) In general, the total mixture pressure affects the mixture composition. The equilibrium constant for the reaction $N_2 + O_2 \rightleftharpoons 2NO$ can be expressed as

$$K_p = \frac{N_{NO}^{v_{NO}}}{N_{N_2}^{v_{N_2}} N_{O_2}^{v_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{NO} - v_{N_2} - v_{O_2})}$$

The value of the exponent in this case is $2-1-1 = 0$. Therefore, changing the total mixture pressure will have no effect on the number of moles of N_2 , O_2 and NO .

16-4C (a) The equilibrium constant for the reaction $CO + \frac{1}{2}O_2 \rightleftharpoons CO_2$ can be expressed as

$$K_p = \frac{N_{CO_2}^{v_{CO_2}}}{N_{CO}^{v_{CO}} N_{O_2}^{v_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{CO_2} - v_{CO} - v_{O_2})}$$

Judging from the values in Table A-28, the K_p value for this reaction decreases as temperature increases. That is, the indicated reaction will be less complete at higher temperatures. Therefore, the number of moles of CO_2 will decrease and the number moles of CO and O_2 will increase as the temperature increases.

(b) The value of the exponent in this case is $1-1-0.5=-0.5$, which is negative. Thus as the pressure increases, the term in the brackets will decrease. The value of K_p depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products (CO_2) must increase, and the number of moles of the reactants (CO , O_2) must decrease.

16-5C (a) The equilibrium constant for the reaction $\text{N}_2 \rightleftharpoons 2\text{N}$ can be expressed as

$$K_p = \frac{N_{\text{N}}^{\nu_{\text{N}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{N}} - \nu_{\text{N}_2})}$$

Judging from the values in Table A-28, the K_p value for this reaction increases as the temperature increases. That is, the indicated reaction will be more complete at higher temperatures. Therefore, the number of moles of N will increase and the number moles of N_2 will decrease as the temperature increases.

(b) The value of the exponent in this case is $2-1 = 1$, which is positive. Thus as the pressure increases, the term in the brackets also increases. The value of K_p depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products (N) must decrease, and the number of moles of the reactants (N_2) must increase.

16-6C The equilibrium constant for the reaction $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$ can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

Adding more N_2 (an inert gas) at constant temperature and pressure will increase N_{total} but will have no direct effect on other terms. Then to keep the equation balanced, the number of moles of the products (CO_2) must increase, and the number of moles of the reactants (CO, O_2) must decrease.

16-7C The values of the equilibrium constants for each dissociation reaction at 3000 K are, from Table A-28,

Thus H_2 is more likely to dissociate than N_2 .

16-8C (a) This reaction is the reverse of the known CO reaction. The equilibrium constant is then

$$1/K_p$$

(b) This reaction is the reverse of the known CO reaction at a different pressure. Since pressure has no effect on the equilibrium constant,

$$1/K_p$$

(c) This reaction is the same as the known CO reaction multiplied by 2. The equilibrium constant is then

$$K_p^2$$

(d) This is the same as reaction (c) occurring at a different pressure. Since pressure has no effect on the equilibrium constant,

$$K_p^2$$

16-9C (a) This reaction is the reverse of the known H₂O reaction. The equilibrium constant is then

$$1/K_P$$

(b) This reaction is the reverse of the known H₂O reaction at a different pressure. Since pressure has no effect on the equilibrium constant,

$$1/K_P$$

(c) This reaction is the same as the known H₂O reaction multiplied by 3. The equilibrium constant is then

$$K_P^3$$

(d) This is the same as reaction (c) occurring at a different pressure. Since pressure has no effect on the equilibrium constant,

$$K_P^3$$

16-10 The partial pressures of the constituents of an ideal gas mixture is given. The Gibbs function of the nitrogen in this mixture at the given mixture pressure and temperature is to be determined.

Analysis The partial pressure of nitrogen is

$$P_{N_2} = 110 \text{ kPa} = (110/101.325) = 1.086 \text{ atm}$$

The Gibbs function of nitrogen at 293 K and 1.086 atm is

$$\begin{aligned}\bar{g}(293 \text{ K}, 1.086 \text{ atm}) &= \bar{g}^*(293 \text{ K}, 1 \text{ atm}) + R_u T \ln P_{N_2} \\ &= 0 + (8.314 \text{ kJ/kmol.K})(293 \text{ K}) \ln(1.086 \text{ atm}) \\ &= \mathbf{200 \text{ kJ/kmol}}\end{aligned}$$

N₂, CO₂, NO

$$\begin{array}{l}P_{N_2} = 110 \text{ kPa} \\ 293 \text{ K}\end{array}$$

16-11 The mole fractions of the constituents of an ideal gas mixture is given. The Gibbs function of the N₂ in this mixture at the given mixture pressure and temperature is to be determined.

Analysis From Tables A-18 and A-26, at 1 atm pressure,

$$\begin{aligned}\bar{g}^*(600 \text{ K}, 1 \text{ atm}) &= \bar{g}_f^o + \Delta[\bar{h}(T) - T\bar{s}^o(T)] \\ &= 0 + (17,563 - 600 \times 212.066) - (8669 - 298 \times 191.502) \\ &= -61,278 \text{ kJ/kmol}\end{aligned}$$

The partial pressure of N₂ is

$$P_{CO} = y_{N_2} P = (0.30)(5 \text{ atm}) = 1.5 \text{ atm}$$

30% N₂
30% O₂
40% H₂O
5 atm
600 K

The Gibbs function of N₂ at 600 K and 1.5 atm is

$$\begin{aligned}\bar{g}(600 \text{ K}, 1.5 \text{ atm}) &= \bar{g}^*(600 \text{ K}, 1 \text{ atm}) + R_u T \ln P_{CO} \\ &= -61,278 \text{ kJ/kmol} + (8.314 \text{ kJ/kmol})(600 \text{ K}) \ln(1.5 \text{ atm}) \\ &= \mathbf{-59,260 \text{ kJ/kmol}}\end{aligned}$$

16-12 The temperature at which 0.2 percent of diatomic oxygen dissociates into monatomic oxygen at two pressures is to be determined.

Assumptions 1 The equilibrium composition consists of N₂ and N. **2** The constituents of the mixture are ideal gases.

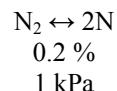

Analysis (a) The stoichiometric and actual reactions can be written as

Stoichiometric: N₂ ⇌ 2N (thus $\nu_{N_2} = 1$ and $\nu_N = 2$)

Actual: N₂ ⇌ $\underbrace{0.998N_2}_{\text{react.}} + \underbrace{0.004N}_{\text{prod.}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_N^{\nu_N}}{N_{N_2}^{\nu_{N_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_N - \nu_{N_2}} = \frac{0.004^2}{0.998} \left(\frac{1/101.325}{0.998 + 0.004} \right)^{2-1} = 1.579 \times 10^{-7}$$

and

$$\ln K_p = -15.66$$

From Table A-28, the temperature corresponding to this $\ln K_p$ value is

$$T = \mathbf{3628 \text{ K}}$$

(b) At 10 kPa,

$$K_p = \frac{N_N^{\nu_N}}{N_{N_2}^{\nu_{N_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_N - \nu_{N_2}} = \frac{0.004^2}{0.998} \left(\frac{10/101.325}{0.998 + 0.004} \right)^{2-1} = 1.579 \times 10^{-6}$$

$$\ln K_p = -13.36$$

From Table A-28, the temperature corresponding to this $\ln K_p$ value is

$$T = \mathbf{3909 \text{ K}}$$

16-13 The equilibrium constant of the reaction $\text{H}_2\text{O} \rightleftharpoons \text{H}_2 + \frac{1}{2}\text{O}_2$ is to be determined using Gibbs function.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 500 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{H}_2}(\bar{h} - T\bar{s})_{\text{H}_2} + \nu_{\text{O}_2}(\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{H}_2\text{O}}(\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= \nu_{\text{H}_2}[(\bar{h}_f + \bar{h}_{500} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad + \nu_{\text{O}_2}[(\bar{h}_f + \bar{h}_{500} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{H}_2\text{O}}[(\bar{h}_f + \bar{h}_{500} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &= 1 \times (0 + 14,350 - 8468 - 500 \times 145.628) \\ &\quad + 0.5 \times (0 + 14,770 - 8682 - 500 \times 220.589) \\ &\quad - 1 \times (-241,820 + 16,828 - 9904 - 500 \times 206.413) \\ &= 219,067 \text{ kJ/kmol} \end{aligned}$$

500 K

Substituting,

$$\ln K_p = -(219,067 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(500 \text{ K})] = -52.70$$

or

$$K_p = 1.30 \times 10^{-23} \quad (\text{Table A - 28: } \ln K_p = -52.70)$$

At 2000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{H}_2}(\bar{h} - T\bar{s})_{\text{H}_2} + \nu_{\text{O}_2}(\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{H}_2\text{O}}(\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= \nu_{\text{H}_2}[(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad + \nu_{\text{O}_2}[(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{H}_2\text{O}}[(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &= 1 \times (0 + 61,400 - 8468 - 2000 \times 188.297) \\ &\quad + 0.5 \times (0 + 67,881 - 8682 - 2000 \times 268.655) \\ &\quad - 1 \times (-241,820 + 82,593 - 9904 - 2000 \times 264.571) \\ &= 135,556 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(135,556 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})] = -8.15$$

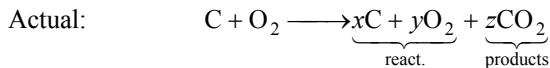

or

$$K_p = 2.88 \times 10^{-4} \quad (\text{Table A - 28: } \ln K_p = -8.15)$$

16-14 The reaction $C + O_2 \rightleftharpoons CO_2$ is considered. The mole fraction of the carbon dioxide produced when this reaction occurs at 1 atm and 3800 K are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , C and O_2 . 2 The constituents of the mixture are ideal gases.

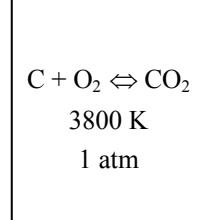

Analysis The stoichiometric and actual reactions in this case are

C balance: $1 = x + z \longrightarrow z = 1 - x$

O balance: $2 = 2y + 2z \longrightarrow y = 1 - z = 1 - (1 - x) = x$

Total number of moles: $N_{\text{total}} = x + y + z = 1 + x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{CO_2}^{\nu_{CO_2}}}{N_C^{\nu_C} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{CO_2} - \nu_C - \nu_{O_2})}$$

From the problem statement at 3800 K, $\ln K_p = -0.461$. Then,

$$K_p = \exp(-0.461) = 0.6307$$

Substituting,

$$0.6307 = \frac{(1-x)}{(x)(x)} \left(\frac{1}{1+x} \right)^{1-1-1}$$

Solving for x ,

$$x = 0.7831$$

Then,

$$y = x = 0.7831$$

$$z = 1 - x = 0.2169$$

Therefore, the equilibrium composition of the mixture at 3800 K and 1 atm is

The mole fraction of carbon dioxide is

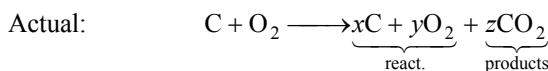

$$y_{CO_2} = \frac{N_{CO_2}}{N_{\text{total}}} = \frac{0.2169}{1 + 0.7831} = \mathbf{0.1216}$$

16-15 The reaction $C + O_2 \rightleftharpoons CO_2$ is considered. The mole fraction of the carbon dioxide produced when this reaction occurs at 1 atm and 3800 K and 700 kPa and 3800 K are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , C and O_2 . **2** The constituents of the mixture are ideal gases.

Analysis We first solve the problem for 1 atm pressure:

The stoichiometric and actual reactions in this case are

C balance: $1 = x + z \longrightarrow z = 1 - x$

O balance: $2 = 2y + 2z \longrightarrow y = 1 - z = 1 - (1 - x) = x$

Total number of moles: $N_{\text{total}} = x + y + z = 1 + x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{CO_2}^{\nu_{CO_2}}}{N_C^{\nu_C} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{CO_2} - \nu_C - \nu_{O_2})}$$

From the problem statement at 3800 K, $\ln K_p = -0.461$. Then,

$$K_p = \exp(-0.461) = 0.6307$$

Substituting,

$$0.6307 = \frac{(1-x)}{(x)(x)} \left(\frac{1}{1+x} \right)^{1-1-1}$$

Solving for x ,

$$x = 0.7831$$

Then,

$$y = x = 0.7831$$

$$z = 1 - x = 0.2169$$

Therefore, the equilibrium composition of the mixture at 3800 K and 1 atm is

The mole fraction of carbon dioxide is

$$\gamma_{CO_2} = \frac{N_{CO_2}}{N_{\text{total}}} = \frac{0.2169}{1 + 0.7831} = \mathbf{0.1216}$$

We repeat the calculations at 700 kPa pressure:

The pressure in this case is $700 \text{ kPa}/(101.325 \text{ kPa/atm}) = 6.908 \text{ atm}$. Then,

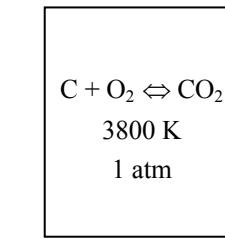

$$K_p = \frac{N_{CO_2}^{\nu_{CO_2}}}{N_C^{\nu_C} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{CO_2} - \nu_C - \nu_{O_2})}$$

$$0.6307 = \frac{(1-x)}{(x)(x)} \left(\frac{6.908}{1+x} \right)^{1-1-1}$$

$$x = 0.4320$$

$$y = x = 0.4320$$

$$z = 1 - x = 0.5680$$

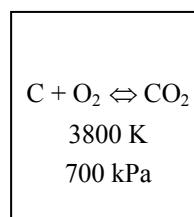

Therefore, the equilibrium composition of the mixture at 3800 K and 700 kPa is

The mole fraction of carbon dioxide is

$$\gamma_{CO_2} = \frac{N_{CO_2}}{N_{\text{total}}} = \frac{0.5680}{1 + 0.4320} = \mathbf{0.3966}$$

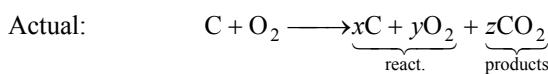

16-16 The reaction $C + O_2 \rightleftharpoons CO_2$ is considered. The mole fraction of the carbon dioxide produced when this reaction occurs at 1 atm and 3800 K and 700 kPa and 3800 K are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , C and O_2 . 2 The constituents of the mixture are ideal gases.

Analysis We first solve the problem for the reaction $C + O_2 \rightleftharpoons CO_2$:

The stoichiometric and actual reactions in this case are

C balance: $1 = x + z \longrightarrow z = 1 - x$

O balance: $2 = 2y + 2z \longrightarrow y = 1 - z = 1 - (1 - x) = x$

Total number of moles: $N_{\text{total}} = x + y + z = 1 + x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{CO_2}^{\nu_{CO_2}}}{N_C^{\nu_C} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{CO_2} - \nu_C - \nu_{O_2})}$$

From the problem statement at 3800 K, $\ln K_p = -0.461$. Then,

$$K_p = \exp(-0.461) = 0.6307$$

Substituting,

$$0.6307 = \frac{(1-x)}{(x)(x)} \left(\frac{1}{1+x} \right)^{1-1-1}$$

Solving for x ,

$$x = 0.7831$$

Then,

$$y = x = 0.7831$$

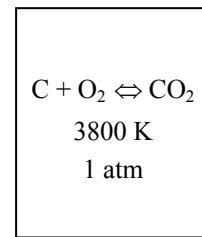

$$z = 1 - x = 0.2169$$

Therefore, the equilibrium composition of the mixture at 3800 K and 1 atm is

The mole fraction of carbon dioxide is

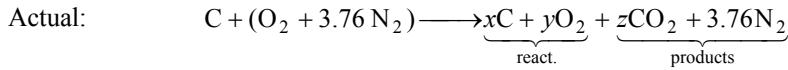

$$\gamma_{CO_2} = \frac{N_{CO_2}}{N_{\text{total}}} = \frac{0.2169}{1 + 0.7831} = \mathbf{0.1216}$$

If the reaction is: $\text{C} + (\text{O}_2 + 3.76 \text{ N}_2) \rightleftharpoons \text{CO}_2 + 3.76 \text{ N}_2$

The stoichiometric and actual reactions in this case are

Stoichiometric:

C balance: $1 = x + z \longrightarrow z = 1 - x$

O balance: $2 = 2y + 2z \longrightarrow y = 1 - z = 1 - (1 - x) = x$

Total number of moles: $N_{\text{total}} = x + y + z + 3.76 = 4.76 + x$

$\text{C} + (\text{O}_2 + 3.76 \text{ N}_2) \rightleftharpoons \text{CO}_2 + 3.76 \text{ N}_2$
3800 K
1 atm

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}} N_{\text{N}_2}^{\nu_{\text{N}_2}}}{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{O}_2}^{\nu_{\text{O}_2}} N_{\text{N}_2}^{\nu_{\text{N}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} + \nu_{\text{N}_2} - \nu_{\text{C}} - \nu_{\text{O}_2} - \nu_{\text{N}_2})}$$

or $K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{C}} - \nu_{\text{O}_2})}$

From the problem statement at 3800 K, $\ln K_p = 12.49$. Then,

$$K_p = \exp(12.49) = 265,670$$

Substituting,

$$265,670 = \frac{(1-x)}{(x)(x)} \left(\frac{1}{4.76+x} \right)^{-1}$$

Solving for x ,

$$x = 0.004226$$

Then,

$$y = x = 0.004226$$

$$z = 1 - x = 0.9958$$

Therefore, the equilibrium composition of the mixture at 3800 K and 1 atm is

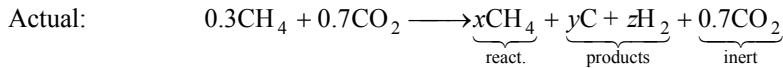

The mole fraction of carbon dioxide is

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{total}}} = \frac{0.9958}{4.76 + 0.004226} = \mathbf{0.2090}$$

16-17 A gaseous mixture consisting of methane and carbon dioxide is heated. The equilibrium composition (by mole fraction) of the resulting mixture is to be determined.

Assumptions 1 The equilibrium composition consists of CH₄, C, H₂, and CO₂. 2 The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

C balance: 0.3 = $x + y \longrightarrow y = 0.3 - x$

H balance: 1.2 = 4x + 2z → z = 0.6 - 2x

Total number of moles: $N_{\text{total}} = x + y + z + 1 = 1.6 - 2x$

CH₄, CO₂
1200 K
1 atm

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CH}_4}^{\nu_{\text{CH}_4}}}{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{H}_2}^{\nu_{\text{H}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CH}_4} - \nu_{\text{C}} - \nu_{\text{H}_2}}$$

From the problem statement at 1200 K, $\ln K_p = 4.147$. Then,

$$K_p = \exp(4.147) = 63.244$$

For the reverse reaction that we consider,

$$K_p = 1/63.244 = 0.01581$$

Substituting,

$$0.01581 = \frac{x}{(0.3 - x)(0.6 - 2x)^2} \left(\frac{1}{1.6 - 2x} \right)^{1-1-2}$$

Solving for x,

$$x = 0.0006637$$

Then,

$$y = 0.3 - x = 0.2993$$

$$z = 0.6 - 2x = 0.5987$$

Therefore, the equilibrium composition of the mixture at 1200 K and 1 atm is

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_{\text{total}}} = \frac{0.0006637}{1.6 - 2 \times 0.0006637} = \frac{0.0006637}{1.599} = \mathbf{0.000415}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_{\text{total}}} = \frac{0.2993}{1.599} = \mathbf{0.1872}$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{0.5987}{1.599} = \mathbf{0.3745}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{total}}} = \frac{0.7}{1.599} = \mathbf{0.4379}$$

16-18 The dissociation reaction $\text{CO}_2 \rightleftharpoons \text{CO} + \text{O}$ is considered. The composition of the products at given pressure and temperature is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , and O . **2** The constituents of the mixture are ideal gases.

Analysis For the stoichiometric reaction $\text{CO}_2 \rightleftharpoons \text{CO} + \frac{1}{2}\text{O}_2$, from Table A-28, at 2500 K

$$\ln K_p = -3.331$$

For the oxygen dissociation reaction $0.5\text{O}_2 \rightleftharpoons \text{O}$, from Table A-28, at 2500 K,

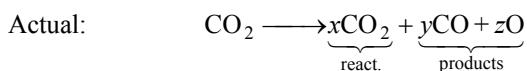

$$\ln K_p = -8.509 / 2 = -4.255$$

For the desired stoichiometric reaction $\text{CO}_2 \rightleftharpoons \text{CO} + \text{O}$ (thus $\nu_{\text{CO}_2} = 1$, $\nu_{\text{CO}} = 1$ and $\nu_{\text{O}} = 1$),

$$\ln K_p = -3.331 - 4.255 = -7.586$$

and

$$K_p = \exp(-7.586) = 0.0005075$$

C balance: $1 = x + y \longrightarrow y = 1 - x$

O balance: $2 = 2x + y + z \longrightarrow z = 1 - x$

Total number of moles: $N_{\text{total}} = x + y + z = 2 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CO}} + \nu_{\text{O}} - \nu_{\text{CO}_2}}$$

Substituting,

$$0.0005075 = \frac{(1-x)(1-x)}{x} \left(\frac{1}{2-x} \right)^{1+1-1}$$

Solving for x ,

$$x = 0.9775$$

Then,

$$y = 1 - x = 0.0225$$

$$z = 1 - x = 0.0225$$

Therefore, the equilibrium composition of the mixture at 2500 K and 1 atm is

$$\mathbf{0.9775 \text{ CO}_2 + 0.0225 \text{ CO} + 0.0225 \text{ O}}$$

CO_2
2500 K
1 atm

16-19 The dissociation reaction $\text{CO}_2 \rightleftharpoons \text{CO} + \text{O}$ is considered. The composition of the products at given pressure and temperature is to be determined when nitrogen is added to carbon dioxide.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , O , and N_2 . **2** The constituents of the mixture are ideal gases.

Analysis For the stoichiometric reaction $\text{CO}_2 \rightleftharpoons \text{CO} + \frac{1}{2}\text{O}_2$, from Table A-28, at 2500 K

$$\ln K_p = -3.331$$

For the oxygen dissociation reaction $0.5\text{O}_2 \rightleftharpoons \text{O}$, from Table A-28, at 2500 K,

$$\ln K_p = -8.509 / 2 = -4.255$$

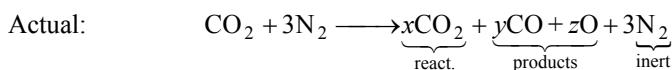

$\text{CO}_2, 3\text{N}_2$
2500 K
1 atm

For the desired stoichiometric reaction $\text{CO}_2 \rightleftharpoons \text{CO} + \text{O}$ (thus $v_{\text{CO}_2} = 1$, $v_{\text{CO}} = 1$ and $v_{\text{O}} = 1$),

$$\ln K_p = -3.331 - 4.255 = -7.586$$

and

$$K_p = \exp(-7.586) = 0.0005075$$

C balance: $1 = x + y \longrightarrow y = 1 - x$

O balance: $2 = 2x + y + z \longrightarrow z = 1 - x$

Total number of moles: $N_{\text{total}} = x + y + z + 3 = 5 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}}^{v_{\text{O}}}}{N_{\text{CO}_2}^{v_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_{\text{CO}} + v_{\text{O}} - v_{\text{CO}_2}}$$

Substituting,

$$0.0005075 = \frac{(1-x)(1-x)}{x} \left(\frac{1}{5-x} \right)^{1+1-1}$$

Solving for x ,

$$x = 0.9557$$

Then,

$$y = 1 - x = 0.0443$$

$$z = 1 - x = 0.0443$$

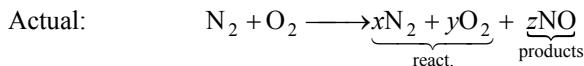

Therefore, the equilibrium composition of the mixture at 2500 K and 1 atm is

$$\mathbf{0.9557 \text{ CO}_2 + 0.0443 \text{ CO} + 0.0443 \text{ O} + 3\text{N}_2}$$

16-20 The reaction $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$ is considered. The equilibrium mole fraction of NO 1600 K and 1 atm is to be determined.

Assumptions 1 The equilibrium composition consists of N_2 , O_2 , and NO. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

$$\text{N balance: } 2 = 2x + z \longrightarrow z = 2 - 2x$$

$$\text{O balance: } 2 = 2y + z \longrightarrow y = x$$

$$\text{Total number of moles: } N_{\text{total}} = x + y + z = 2$$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{v_{\text{NO}}}}{N_{\text{N}_2}^{v_{\text{N}_2}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{NO}} - v_{\text{N}_2} - v_{\text{O}_2})}$$

From Table A-28, at 1600 K, $\ln K_p = -5.294$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 5.294) = 2.522 \times 10^{-5}$$

Substituting,

$$2.522 \times 10^{-5} = \frac{(2 - 2x)^2}{x^2} \left(\frac{1}{2} \right)^{2-1-1}$$

Solving for x ,

$$x = 0.9975$$

Then,

$$y = x = 0.9975$$

$$z = 2 - 2x = 0.005009$$

Therefore, the equilibrium composition of the mixture at 1000 K and 1 atm is

The mole fraction of NO is then

$$\gamma_{\text{NO}} = \frac{N_{\text{NO}}}{N_{\text{total}}} = \frac{0.005009}{2} = \mathbf{0.002505}$$

N ₂ , O ₂
1600 K
1 atm

16-21E The equilibrium constant of the reaction $\text{H}_2 + 1/2\text{O}_2 \leftrightarrow \text{H}_2\text{O}$ is listed in Table A-28 at different temperatures. The data are to be verified at two temperatures using Gibbs function data.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

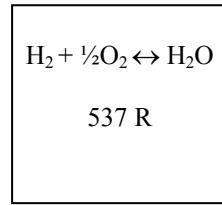

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 537 R,

$$\Delta G^*(T) = 1(-98,350) - 1(0) - 0.5(0) = -98,350 \text{ Btu/lbmol}$$

Substituting,

$$\ln K_p = -(-98,350 \text{ Btu/lbmol}) / [(1.986 \text{ Btu/lbmol}\cdot\text{R})(537 \text{ R})] = 92.22$$

or

$$K_p = 1.12 \times 10^{40} \quad (\text{Table A-28: } \ln K_p = 92.21)$$

(b) At 4320 R,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{H}_2\text{O}}(\bar{h} - T\bar{s})_{\text{H}_2\text{O}} - \nu_{\text{H}_2}(\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{O}_2}(\bar{h} - T\bar{s})_{\text{O}_2} \\ &= \nu_{\text{H}_2\text{O}}[(\bar{h}_f + \bar{h}_{4320} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &\quad - \nu_{\text{H}_2}[(\bar{h}_f + \bar{h}_{4320} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad - \nu_{\text{O}_2}[(\bar{h}_f + \bar{h}_{4320} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &= 1 \times (-104,040 + 44,533 - 4258 - 4320 \times 65.504) \\ &\quad - 1 \times (0 + 32,647.2 - 3640.3 - 4320 \times 46.554) \\ &\quad - 0.5 \times (0 + 35,746 - 3725.1 - 4320 \times 65.831) \\ &= -48,451 \text{ Btu/lbmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(-48,451 \text{ Btu/lbmol}) / [(1.986 \text{ Btu/lbmol}\cdot\text{R})(4320 \text{ R})] = 5.647$$

or

$$K_p = 283 \quad (\text{Table A-28: } \ln K_p = 5.619)$$

Discussion Solving this problem using EES with the built-in ideal gas properties give $K_p = 1.04 \times 10^{40}$ for part (a) and $K_p = 278$ for part (b).

16-22 The equilibrium constant of the reaction $\text{CO} + 1/2\text{O}_2 \leftrightarrow \text{CO}_2$ at 298 K and 2000 K are to be determined, and compared with the values listed in Table A-28.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

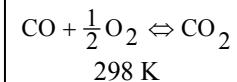

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 298 K,

$$\Delta G^*(T) = 1(-394,360) - 1(-137,150) - 0.5(0) = -257,210 \text{ kJ/kmol}$$

where the Gibbs functions are obtained from Table A-26. Substituting,

$$\ln K_p = -\frac{(-257,210 \text{ kJ/kmol})}{(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})} = \mathbf{103.81}$$

From Table A-28: $\ln K_p = \mathbf{103.76}$

(b) At 2000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} - \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= 1[(-302,128) - (2000)(309.00)] - 1[(-53,826) - (2000)(258.48)] - 0.5[(59,193) - (2000)(268.53)] \\ &= -110,409 \text{ kJ/kmol} \end{aligned}$$

The enthalpies at 2000 K and entropies at 2000 K and 101.3 kPa (1 atm) are obtained from EES. Substituting,

$$\ln K_p = -\frac{(-110,409 \text{ kJ/kmol})}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})} = \mathbf{6.64}$$

From Table A-28:

$$\ln K_p = \mathbf{6.635}$$

16-23 The effect of varying the percent excess air during the steady-flow combustion of hydrogen is to be studied.

Analysis The combustion equation of hydrogen with stoichiometric amount of air is

For the incomplete combustion with 100% excess air, the combustion equation is

The coefficients are to be determined from the mass balances

$$\text{Hydrogen balance: } 2 = 0.97 \times 2 + a \times 2 \longrightarrow a = 0.03$$

$$\text{Oxygen balance: } (1+Ex) \times 0.5 \times 2 = 0.97 + b \times 2$$

$$\text{Nitrogen balance: } (1+Ex) \times 0.5 \times 3.76 \times 2 = c \times 2$$

Solving the above equations, we find the coefficients ($Ex = 1, a = 0.03, b = 0.515, c = 3.76$) and write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 0.97 + 0.03 + 0.515 + 3.76 = 5.275$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2\text{O}}$$

The equilibrium constant is also given by

$$K_p = \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} \frac{ab^{0.5}}{0.97^1} = \left(\frac{1}{5.275} \right)^{0.5} \frac{(0.03)(0.515)^{0.5}}{0.97} = 0.009664$$

$$\text{and} \quad \ln K_p = \ln(0.009664) = -4.647$$

The corresponding temperature is obtained solving the above equations using EES to be

$$T_{\text{prod}} = 2600 \text{ K}$$

This is the temperature at which 97 percent of H_2 will burn into H_2O . The copy of EES solution is given next.

16-24 The equilibrium constant of the reaction $\text{CH}_4 + 2\text{O}_2 \leftrightarrow \text{CO}_2 + 2\text{H}_2\text{O}$ at 25°C is to be determined.

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 25°C,

$$\Delta G^*(T) = 1(-394,360) + 2(-228,590) - 1(-50,790) - 2(0) = -800,750 \text{ kJ / kmol}$$

Substituting,

$$\ln K_p = -(-800,750 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = 323.04$$

or $K_p = 1.96 \times 10^{140}$

16-25 The equilibrium constant of the reaction $\text{CO}_2 \leftrightarrow \text{CO} + 1/2\text{O}_2$ is listed in Table A-28 at different temperatures. It is to be verified using Gibbs function data.

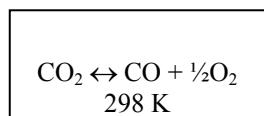

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where $\Delta G^*(T) = \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T)$

At 298 K,

$$\Delta G^*(T) = 1(-137,150) + 0.5(0) - 1(-394,360) = 257,210 \text{ kJ/kmol}$$

Substituting,

$$\ln K_p = -(257,210 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = -103.81$$

or $K_p = 8.24 \times 10^{-46}$ (Table A-28 : $\ln K_p = -103.76$)

(b) At 1800 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) \\ &= \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} \\ &= \nu_{\text{CO}} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{CO}} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{CO}_2} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{CO}_2} \\ &= 1 \times (-110,530 + 58,191 - 8669 - 1800 \times 254.797) \\ &\quad + 0.5 \times (0 + 60,371 - 8682 - 1800 \times 264.701) \\ &\quad - 1 \times (-393,520 + 88,806 - 9364 - 1800 \times 302.884) \\ &= 127,240.2 \text{ kJ/kmol} \end{aligned}$$

Substituting, $\ln K_p = -(127,240.2 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(1800 \text{ K})] = -8.502$

or $K_p = 2.03 \times 10^{-4}$ (Table A-28 : $\ln K_p = -8.497$)

16-26 Carbon monoxide is burned with 100 percent excess air. The temperature at which 93 percent of CO burn to CO_2 is to be determined.

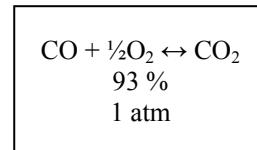

Assumptions 1 The equilibrium composition consists of CO_2 , CO, O_2 , and N_2 . 2 The constituents of the mixture are ideal gases.

Analysis Assuming N_2 to remain as an inert gas, the stoichiometric and actual reactions can be written as

The equilibrium constant K_p can be determined from

$$\begin{aligned} K_p &= \frac{N_{\text{CO}_2}^{v_{\text{CO}_2}}}{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{CO}_2} - v_{\text{CO}} - v_{\text{O}_2})} \\ &= \frac{0.93}{0.07 \times 0.535^{0.5}} \left(\frac{1}{0.93 + 0.07 + 0.535 + 3.76} \right)^{1-1.5} \\ &= 41.80 \end{aligned}$$

and

$$\ln K_p = 3.733$$

From Table A-28, the temperature corresponding to this K_p value is $T = 2424 \text{ K}$

16-27 Problem 16-26 is reconsidered. The effect of varying the percent excess air during the steady-flow process from 0 to 200 percent on the temperature at which 93 percent of CO burn into CO₂ is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

"To solve this problem, we need to give EES a guess value for T_{prod} other than the default value of 1. Set the guess value of T_{prod} to 1000 K by selecting Variable Information in the Options menu. Then press F2 or click the Calculator icon."

16-28E Carbon monoxide is burned with 100 percent excess air. The temperature at which 93 percent of CO burn to CO₂ is to be determined.

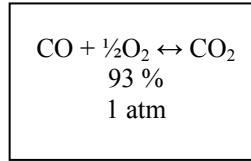

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis Assuming N₂ to remain as an inert gas, the stoichiometric and actual reactions can be written as

The equilibrium constant K_p can be determined from

$$\begin{aligned} K_p &= \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})} \\ &= \frac{0.93}{0.07 \times 0.535^{0.5}} \left(\frac{1}{0.93 + 0.07 + 0.535 + 3.76} \right)^{1-1.5} \\ &= 41.80 \end{aligned}$$

and

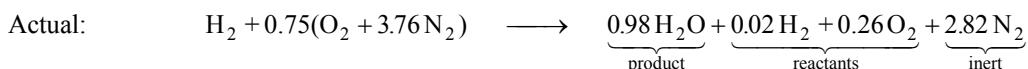

$$\ln K_p = 3.733$$

From Table A-28, the temperature corresponding to this K_p value is T = 2424 K = 4363 R

16-29 Hydrogen is burned with 150 percent theoretical air. The temperature at which 98 percent of H₂ will burn to H₂O is to be determined.

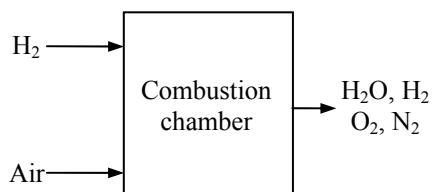

Assumptions 1 The equilibrium composition consists of H₂O, H₂, O₂, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis Assuming N₂ to remain as an inert gas, the stoichiometric and actual reactions can be written as

The equilibrium constant K_p can be determined from

$$\begin{aligned} K_p &= \frac{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}}{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2\text{O}} - \nu_{\text{H}_2} - \nu_{\text{O}_2})} \\ &= \frac{0.98}{0.02 \times 0.26^{0.5}} \left(\frac{1}{0.98 + 0.02 + 0.26 + 2.82} \right)^{1-1.5} \\ &= 194.11 \end{aligned}$$

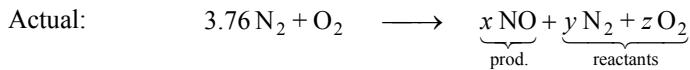

From Table A-28, the temperature corresponding to this K_p value is T = 2472 K.

16-30 Air is heated to a high temperature. The equilibrium composition at that temperature is to be determined.

Assumptions 1 The equilibrium composition consists of N₂, O₂, and NO. 2 The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

N balance: $7.52 = x + 2y$ or $y = 3.76 - 0.5x$

O balance: $2 = x + 2z$ or $z = 1 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z = x + 4.76 - x = 4.76$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, $\ln K_p = -3.931$ at 2000 K. Thus $K_p = 0.01962$. Substituting,

$$0.01962 = \frac{x}{(3.76 - 0.5x)^{0.5} (1 - 0.5x)^{0.5}} \left(\frac{2}{4.76} \right)^{1-1}$$

Solving for x ,

$$x = 0.0376$$

Then,

$$y = 3.76 - 0.5x = 3.7412$$

$$z = 1 - 0.5x = 0.9812$$

Therefore, the equilibrium composition of the mixture at 2000 K and 2 atm is

The equilibrium constant for the reactions $\text{O}_2 \rightleftharpoons 2\text{O}$ ($\ln K_p = -14.622$) and $\text{N}_2 \rightleftharpoons 2\text{N}$ ($\ln K_p = -41.645$) are much smaller than that of the specified reaction ($\ln K_p = -3.931$). Therefore, it is realistic to assume that no monatomic oxygen or nitrogen will be present in the equilibrium mixture. Also the equilibrium composition is in this case independent of pressure since $\Delta\nu = 1 - 0.5 - 0.5 = 0$.

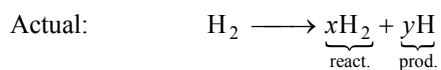

AIR
2000 K
2 atm

16-31 Hydrogen is heated to a high temperature at a constant pressure. The percentage of H₂ that will dissociate into H is to be determined.

Assumptions 1 The equilibrium composition consists of H₂ and H. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: H₂ ⇌ 2H (thus ν_{H₂} = 1 and ν_H = 2)

H balance: 2 = 2x + y or y = 2 - 2x

Total number of moles: N_{total} = x + y = x + 2 - 2x = 2 - x

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_H^{\nu_H}}{N_{H_2}^{\nu_{H_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_H - \nu_{H_2}}$$

H₂
 4000 K
 5 atm

From Table A-28, ln K_p = 0.934 at 4000 K. Thus K_p = 2.545. Substituting,

$$2.545 = \frac{(2 - 2x)^2}{x} \left(\frac{5}{2 - x} \right)^{2-1}$$

Solving for x,

$$x = 0.664$$

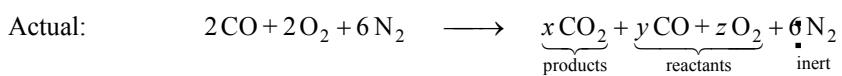

Thus the percentage of H₂ which dissociates to H at 3200 K and 8 atm is

$$1 - 0.664 = 0.336 \text{ or } \mathbf{33.6\%}$$

16-32E A mixture of CO, O₂, and N₂ is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

2 CO
2 O ₂
6 N ₂
4320 R
3 atm

C balance: 2 = x + y → y = 2 - x

O balance: 6 = 2x + y + 2z → z = 2 - 0.5x

Total number of moles: N_{total} = x + y + z + 6 = 10 - 0.5x

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

From Table A-28, ln K_p = 3.860 at T = 4320 R = 2400 K. Thus K_p = 47.465. Substituting,

$$47.465 = \frac{x}{(2-x)(2-0.5x)^{0.5}} \left(\frac{3}{10-0.5x} \right)^{1-1.5}$$

Solving for x,

$$x = 1.930$$

Then,

$$y = 2 - x = 0.070$$

$$z = 2 - 0.5x = 1.035$$

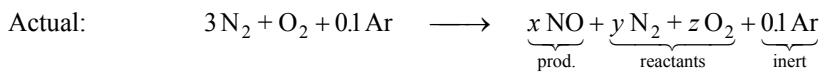

Therefore, the equilibrium composition of the mixture at 2400 K and 3 atm is

16-33 A mixture of N₂, O₂, and Ar is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of N₂, O₂, Ar, and NO. 2 The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

3 N ₂
1 O ₂
0.1 Ar
2400 K
10 atm

N balance: $6 = x + 2y \longrightarrow y = 3 - 0.5x$

O balance: $2 = x + 2z \longrightarrow z = 1 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z + 0.1 = 4.1$

The equilibrium constant relation becomes,

$$K_p = \frac{N_{\text{NO}}^{v_{\text{NO}}}}{N_{\text{N}_2}^{v_{\text{N}_2}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{NO}} - v_{\text{N}_2} - v_{\text{O}_2})} = \frac{x}{y^{0.5} z^{0.5}} \left(\frac{P}{N_{\text{total}}} \right)^{1-0.5-0.5}$$

From Table A-28, $\ln K_p = -3.019$ at 2400 K. Thus $K_p = 0.04885$. Substituting,

$$0.04885 = \frac{x}{(3 - 0.5x)^{0.5} (1 - 0.5x)^{0.5}} \times 1$$

Solving for x ,

$$x = 0.0823$$

Then,

$$y = 3 - 0.5x = 2.9589$$

$$z = 1 - 0.5x = 0.9589$$

Therefore, the equilibrium composition of the mixture at 2400 K and 10 atm is

16-34 The mole fraction of sodium that ionizes according to the reaction $\text{Na} \rightleftharpoons \text{Na}^+ + \text{e}^-$ at 2000 K and 1.5 atm is to be determined.

Assumptions All components behave as ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $\text{Na} \rightleftharpoons \text{Na}^+ + \text{e}^-$ (thus $\nu_{\text{Na}} = 1$, $\nu_{\text{Na}^+} = 1$ and $\nu_{\text{e}^-} = 1$)

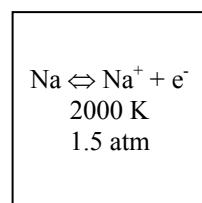

Actual: $\text{Na} \longrightarrow \underbrace{x \text{Na}}_{\text{react.}} + \underbrace{y \text{Na}^+ + y \text{e}^-}_{\text{products}}$

Na balance: $1 = x + y$ or $y = 1 - x$

Total number of moles: $N_{\text{total}} = x + 2y = 2 - x$

The equilibrium constant relation becomes,

$$K_p = \frac{N_{\text{Na}}^{\nu_{\text{Na}}} N_{\text{e}^-}^{\nu_{\text{e}^-}}}{N_{\text{Na}}^{\nu_{\text{Na}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{Na}^+} + \nu_{\text{e}^-} - \nu_{\text{Na}})} = \frac{y^2}{x} \left(\frac{P}{N_{\text{total}}} \right)^{1+1-1}$$

Substituting,

$$0.668 = \frac{(1-x)^2}{x} \left(\frac{1.5}{2-x} \right)$$

Solving for x ,

$$x = 0.4449$$

Thus the fraction of Na which dissociates into Na^+ and e^- is

$$1 - 0.4449 = 0.555 \text{ or } \mathbf{55.5\%}$$

16-35 Oxygen is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

Assumptions 1 The equilibrium composition consists of O₂ and O. **2** The constituents of the mixture are ideal gases.

Analysis (a) Obtaining oxygen properties from table A-19, an energy balance gives

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$\begin{aligned} q_{\text{in}} &= \bar{u}_2 - \bar{u}_1 \\ &= 57,192 - 6203 \\ &= \mathbf{50,989 \text{ kJ/kmol}} \end{aligned}$$

O ₂
2200 K
1 atm

(b) The stoichiometric and actual reactions in this case are

Stoichiometric: O₂ ⇌ 2O (thus ν_{O₂} = 1 and ν_O = 2)

Actual: O₂ → $\underbrace{x\text{O}_2}_{\text{react.}} + \underbrace{y\text{O}}_{\text{products}}$

O balance: 2 = 2x + y → y = 2 - 2x

Total number of moles: N_{total} = x + y = 2 - x

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_O^{\nu_O}}{N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{\text{O}_2}}$$

From Table A-28, at 2200 K, ln K_p = -11.827. Then,

$$K_p = \exp(-11.827) = 7.305 \times 10^{-6}$$

Substituting,

$$7.305 \times 10^{-6} = \frac{(2-2x)^2}{x} \left(\frac{1}{2-x} \right)^{2-1}$$

Solving for x,

$$x = 0.99865$$

Then,

$$y = 2 - 2x = 0.0027$$

Therefore, the equilibrium composition of the mixture at 2200 K and 1 atm is

Hence, the oxygen ions are negligible and the result is same as that in part (a),

$$q_{\text{in}} = \mathbf{50,989 \text{ kJ/kmol}}$$

16-36 Air is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

Assumptions 1 The equilibrium composition consists of O₂ and O, and N₂. 2 The constituents of the mixture are ideal gases.

Analysis (a) Obtaining air properties from table A-17, an energy balance gives

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$\begin{aligned} q_{\text{in}} &= u_2 - u_1 \\ &= 1872.4 - 212.64 \\ &= \mathbf{1660 \text{ kJ/kg}} \end{aligned}$$

O₂, 3.76N₂
2200 K
1 atm

(b) The stoichiometric and actual reactions in this case are

Stoichiometric: O₂ ⇌ 2O (thus ν_{O₂} = 1 and ν_O = 2)

Actual: O₂ + 3.76N₂ → $\underbrace{x\text{O}_2}_{\text{react.}}$ + $\underbrace{y\text{O}}_{\text{products}}$ + $\underbrace{3.76\text{N}_2}_{\text{inert}}$

O balance: 2 = 2x + y → y = 2 - 2x

Total number of moles: N_{total} = x + y + 3.76 = 5.76 - x

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}}$$

From Table A-28, at 2200 K, ln K_p = -11.827. Then,

$$K_p = \exp(-11.827) = 7.305 \times 10^{-6}$$

Substituting,

$$7.305 \times 10^{-6} = \frac{(2 - 2x)^2}{x} \left(\frac{1}{5.76 - x} \right)^{2-1}$$

Solving for x,

$$x = 0.99706$$

Then,

$$y = 2 - 2x = 0.00588$$

Therefore, the equilibrium composition of the mixture at 2200 K and 1 atm is

Hence, the atomic oxygen is negligible and the result is same as that in part (a),

$$q_{\text{in}} = \mathbf{1660 \text{ kJ/kg}}$$

16-37 Liquid propane enters a combustion chamber. The equilibrium composition of product gases and the rate of heat transfer from the combustion chamber are to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, H₂O, CO, N₂, and O₂. **2** The constituents of the mixture are ideal gases.

Analysis (a) Considering 1 kmol of C₃H₈, the stoichiometric combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$2.5a_{\text{th}} = 3 + 2 + 1.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Then the actual combustion equation with 150% excess air and some CO in the products can be written as

After combustion, there will be no C₃H₈ present in the combustion chamber, and H₂O will act like an inert gas. The equilibrium equation among CO₂, CO, and O₂ can be expressed as

and

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

where

$$N_{\text{total}} = x + (3-x) + (9 - 0.5x) + 4 + 47 = 63 - 0.5x$$

From Table A-28, $\ln K_p = -17.871$ at 1200 K. Thus $K_p = 1.73 \times 10^{-8}$. Substituting,

$$1.73 \times 10^{-8} = \frac{(3-x)(9-0.5x)^{0.5}}{x} \left(\frac{2}{63-0.5x} \right)^{1.5-1}$$

Solving for x ,

$$x = 2.9999999 \approx 3.0$$

Therefore, the amount CO in the product gases is negligible, and it can be disregarded with no loss in accuracy. Then the combustion equation and the equilibrium composition can be expressed as

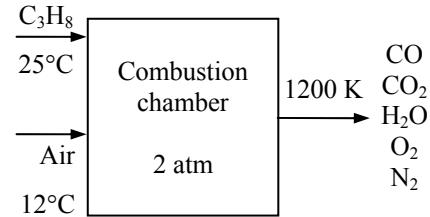

and

(b) The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ on the combustion chamber with $W = 0$,

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables, (The \bar{h}_f° of liquid propane is obtained by adding the h_{fg} at 25°C to \bar{h}_f° of gaseous propane).

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{285\text{ K}}$ kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1200\text{ K}}$ kJ/kmol
$\text{C}_3\text{H}_8(\ell)$	-118,910	---	---	---
O_2	0	8696.5	8682	38,447
N_2	0	8286.5	8669	36,777
$\text{H}_2\text{O}(g)$	-241,820	---	9904	44,380
CO_2	-393,520	---	9364	53,848

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= 3(-393,520 + 53,848 - 9364) + 4(-241,820 + 44,380 - 9904) \\ &\quad + 7.5(0 + 38,447 - 8682) + 47(0 + 36,777 - 8669) \\ &\quad - 1(-118,910 + h_{298} - h_{298}) - 12.5(0 + 8296.5 - 8682) \\ &\quad - 47(0 + 8186.5 - 8669) \\ &= -185,764 \text{ kJ / kmol of C}_3\text{H}_8 \end{aligned}$$

or

$$Q_{\text{out}} = 185,764 \text{ kJ / kmol of C}_3\text{H}_8$$

The mass flow rate of C_3H_8 can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{1.2 \text{ kg / min}}{44 \text{ kg / kmol}} = 0.02727 \text{ kmol / min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{out}} = \dot{N} \times Q_{\text{out}} = (0.02727 \text{ kmol/min})(185,746 \text{ kJ/kmol}) = \mathbf{5066 \text{ kJ/min}}$$

The equilibrium constant for the reaction $\frac{1}{2}\text{N}_2 + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{NO}$ is $\ln K_p = -7.569$, which is very small. This indicates that the amount of NO formed during this process will be very small, and can be disregarded.

16-38 Problem 16-37 is reconsidered. It is to be investigated if it is realistic to disregard the presence of NO in the product gases.

Analysis The problem is solved using EES, and the solution is given below.

"To solve this problem, the Gibbs function of the product gases is minimized. Click on the Min/Max icon."

For this problem at 1200 K the moles of CO are 0.000 and moles of NO are 0.000, thus we can disregard both the CO and NO. However, try some product temperatures above 1286 K and observe the sign change on the Q_out and the amount of CO and NO present as the product temperature increases."

"The reaction of C₃H₈(liq) with excess air can be written:

The coefficients A_th and EX are the theoretical oxygen and the percent excess air on a decimal basis. Coefficients a, b, c, d, e, and f are found by minimizing the Gibbs Free Energy at a total pressure of the product gases P_Prod and the product temperature T_Prod.

The equilibrium solution can be found by applying the Law of Mass Action or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, click on the Min/Max icon. There are six compounds present in the products subject to four species balances, so there are two degrees of freedom. Minimize the Gibbs function of the product gases with respect to two molar quantities such as coefficients b and f. The equilibrium mole numbers a, b, c, d, e, and f will be determined and displayed in the Solution window."

```
PercentEx = 150 [%]

16-39 Oxygen is heated during a steady-flow process. The rate of heat supply needed during this process is to be determined for two cases.

Assumptions 1 The equilibrium composition consists of O₂ and O. **2** All components behave as ideal gases.

Analysis (a) Assuming some O₂ dissociates into O, the dissociation equation can be written as

The equilibrium equation among O₂ and O can be expressed as

Assuming ideal gas behavior for all components, the equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{O}}^{v_{\text{O}}}}{N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_{\text{O}} - v_{\text{O}_2}}$$

where $N_{\text{total}} = x + 2(1-x) = 2 - x$

From Table A-28, $\ln K_p = -4.357$ at 3000 K. Thus $K_p = 0.01282$. Substituting,

$$0.01282 = \frac{(2-2x)^2}{x} \left(\frac{1}{2-x} \right)^{2-1}$$

Solving for x gives

$$x = 0.943$$

Then the dissociation equation becomes

The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ on the combustion chamber with $W = 0$,

$$\dot{Q}_{\text{in}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O₂ and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{3000\text{ K}}$ kJ/kmol
O	249,190	6852	63,425
O ₂	0	8682	106,780

Substituting,

$$\dot{Q}_{\text{in}} = 0.943(0 + 106,780 - 8682) + 0.114(249,190 + 63,425 - 6852) - 0 = 127,363 \text{ kJ / kmol O}_2$$

The mass flow rate of O₂ can be expressed in terms of the mole numbers as

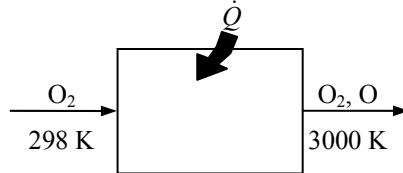

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.5 \text{ kg/min}}{32 \text{ kg/kmol}} = 0.01563 \text{ kmol/min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{in}} = \dot{N} \times \dot{Q}_{\text{in}} = (0.01563 \text{ kmol/min})(127,363 \text{ kJ/kmol}) = \mathbf{1990 \text{ kJ/min}}$$

(b) If no O₂ dissociates into O, then the process involves no chemical reactions and the heat transfer can be determined from the steady-flow energy balance for nonreacting systems to be

$$\dot{Q}_{\text{in}} = \dot{m}(h_2 - h_1) = \dot{N}(\bar{h}_2 - \bar{h}_1) = (0.01563 \text{ kmol/min})(106,780 - 8682) \text{ kJ/kmol} = \mathbf{1533 \text{ kJ/min}}$$

16-40 The equilibrium constant, K_p is to be estimated at 3000 K for the reaction $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 3000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} + \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= 1[(-393,520 + 162,226 - 9364) - (3000)(334.084)] \\ &\quad + 1[(0 + 97,211 - 8468) - (3000)(202.778)] \\ &\quad - 1[(-110,530 + 102,210 - 8669) - (3000)(273.508)] \\ &\quad - 1[(-241,820 + 136,264 - 9904) - (3000)(286.273)] \\ &= 49,291 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -\frac{49,291 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol}\cdot\text{K})(3000 \text{ K})} = -1.9762 \longrightarrow K_p = \mathbf{0.1386}$$

The equilibrium constant may be estimated using the integrated van't Hoff equation:

$$\begin{aligned} \ln\left(\frac{K_{p,\text{est}}}{K_{p1}}\right) &= \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_R} - \frac{1}{T} \right) \\ \ln\left(\frac{K_{p,\text{est}}}{0.2209}\right) &= \frac{-26,176 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol}\cdot\text{K}} \left(\frac{1}{2000 \text{ K}} - \frac{1}{3000 \text{ K}} \right) \longrightarrow K_{p,\text{est}} = \mathbf{0.1307} \end{aligned}$$

16-41 A constant volume tank contains a mixture of H₂ and O₂. The contents are ignited. The final temperature and pressure in the tank are to be determined.

Analysis The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

$$\text{Hydrogen balance: } 2 = 2a + 2b$$

$$\text{Oxygen balance: } 2 = b + 2c$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}})$$

and the Gibbs functions are given by

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{H}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{H}_2\text{O}}$$

The equilibrium constant is also given by

$$K_p = \frac{a^1 c^{0.5}}{b^1} \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{ac^{0.5}}{b} \left(\frac{P_2 / 101.3}{a+b+c} \right)^{0.5}$$

An energy balance on the tank under adiabatic conditions gives

$$U_R = U_P$$

where

$$U_R = 1(\bar{h}_{\text{H}_2@25^\circ\text{C}} - R_u T_{\text{reac}}) + 1(\bar{h}_{\text{O}_2@25^\circ\text{C}} - R_u T_{\text{reac}}) \\ = 0 - (8.314 \text{ kJ/kmol.K})(298.15 \text{ K}) + 0 - (8.314 \text{ kJ/kmol.K})(298.15 \text{ K}) = -4958 \text{ kJ/kmol}$$

$$U_P = a(\bar{h}_{\text{H}_2@T_{\text{prod}}} - R_u T_{\text{prod}}) + b(\bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} - R_u T_{\text{prod}}) + c(\bar{h}_{\text{O}_2@T_{\text{prod}}} - R_u T_{\text{prod}})$$

The relation for the final pressure is

$$P_2 = \frac{N_{\text{tot}}}{N_1} \frac{T_{\text{prod}}}{T_{\text{reac}}} P_1 = \left(\frac{a+b+c}{2} \right) \left(\frac{T_{\text{prod}}}{298.15 \text{ K}} \right) (101.3 \text{ kPa})$$

Solving all the equations simultaneously using EES, we obtain the final temperature and pressure in the tank to be

$$T_{\text{prod}} = \mathbf{3857 \text{ K}}$$

$$P_2 = \mathbf{1043 \text{ kPa}}$$

16-42 It is to be shown that as long as the extent of the reaction, α , for the disassociation reaction $X_2 \rightleftharpoons 2X$ is smaller than one, α is given by $\alpha = \sqrt{\frac{K_p}{4 + K_p}}$

Assumptions The reaction occurs at the reference temperature.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $X_2 \rightleftharpoons 2X$ (thus $v_{X_2} = 1$ and $v_X = 2$)

Actual: $X_2 \rightleftharpoons \underbrace{(1-\alpha)X_2}_{\text{react.}} + \underbrace{2\alpha X}_{\text{prod.}}$

The equilibrium constant K_p is given by

$$K_p = \frac{N_X^{v_X}}{N_{X_2}^{v_{X_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_X - v_{X_2}} = \frac{(2\alpha)^2}{(1-\alpha)} \left(\frac{1}{\alpha+1} \right)^{2-1} = \frac{4\alpha^2}{(1-\alpha)(1+\alpha)}$$

Solving this expression for α gives

$$\alpha = \sqrt{\frac{K_p}{4 + K_p}}$$

Simultaneous Reactions

16-43C It can be expresses as “ $(dG)_{T,P} = 0$ for each reaction.” Or as “the K_p relation for each reaction must be satisfied.”

16-44C The number of K_p relations needed to determine the equilibrium composition of a reacting mixture is equal to the difference between the number of species present in the equilibrium mixture and the number of elements.

16-45 Two chemical reactions are occurring in a mixture. The equilibrium composition at a specified temperature is to be determined.

Assumptions 1 The equilibrium composition consists of H₂O, OH, O₂, and H₂.

2 The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for hydrogen and oxygen yield

$$\text{H balance: } 2 = 2x + 2y + w \quad (1)$$

$$\text{O balance: } 1 = x + 2z + w \quad (2)$$

$\text{H}_2\text{O} \rightleftharpoons \begin{matrix} \text{H}_2\text{O}, \text{OH} \\ \text{O}_2, \text{H}_2 \end{matrix}$ 3400 K 1 atm
--

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3400 K are determined from Table A-28 to be

$$\ln K_{P1} = -1.891 \longrightarrow K_{P1} = 0.15092$$

$$\ln K_{P2} = -1.576 \longrightarrow K_{P2} = 0.20680$$

The K_p relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})} \quad \text{and} \quad K_{P2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

where $N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$

Substituting,

$$0.15092 = \frac{(y)(z)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.20680 = \frac{(w)(y)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 0.574 \quad y = 0.308 \quad z = 0.095 \quad w = 0.236$$

Therefore, the equilibrium composition becomes

16-46 Two chemical reactions are occurring in a mixture. The equilibrium composition at a specified temperature is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and O. **2** The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for carbon and oxygen yield

$$\text{C balance: } 2 = x + y \quad (1)$$

$$\text{O balance: } 6 = 2x + y + 2z + w \quad (2)$$

CO ₂ , CO, O ₂ , O
2000 K
4 atm

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_P relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 2000 K are determined from Table A-28 to be

$$\ln K_{P1} = -6.635 \longrightarrow K_{P1} = 0.001314$$

$$\ln K_{P2} = -14.622 \longrightarrow K_{P2} = 4.464 \times 10^{-7}$$

The K_P relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

$$K_{P2} = \frac{N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{O}} - \nu_{\text{O}_2}}$$

where

$$N_{\text{total}} = N_{\text{CO}_2} + N_{\text{O}_2} + N_{\text{CO}} + N_{\text{O}} = x + y + z + w$$

Substituting,

$$0.001314 = \frac{(y)(z)^{1/2}}{x} \left(\frac{4}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$4.464 \times 10^{-7} = \frac{w^2}{z} \left(\frac{4}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously using an equation solver such as EES for the four unknowns x , y , z , and w yields

$$x = 1.998 \quad y = 0.002272 \quad z = 1.001 \quad w = 0.000579$$

Thus the equilibrium composition is

16-47 Two chemical reactions are occurring at high-temperature air. The equilibrium composition at a specified temperature is to be determined.

Assumptions **1** The equilibrium composition consists of O₂, N₂, O, and NO. **2** The constituents of the mixture are ideal gases.

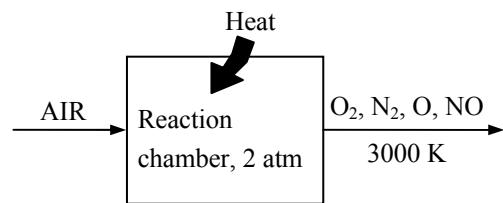

Analysis The reaction equation during this process can be expressed as

Mass balances for nitrogen and oxygen yield

$$\text{N balance: } 7.52 = 2x + y \quad (1)$$

$$\text{O balance: } 2 = y + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3000 K are determined from Table A-28 to be

$$\ln K_{P1} = -2.114 \longrightarrow K_{P1} = 0.12075$$

$$\ln K_{P2} = -4.357 \longrightarrow K_{P2} = 0.01282$$

The K_p relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{NO}^{\nu_{NO}}}{N_{N_2}^{\nu_{N_2}} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{NO} - \nu_{N_2} - \nu_{O_2})}$$

$$K_{P2} = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}}$$

$$\text{where } N_{\text{total}} = N_{N_2} + N_{NO} + N_{O_2} + N_O = x + y + z + w$$

Substituting,

$$0.12075 = \frac{y}{x^{0.5} z^{0.5}} \left(\frac{2}{x + y + z + w} \right)^{1-0.5-0.5} \quad (3)$$

$$0.01282 = \frac{w^2}{z} \left(\frac{2}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously using EES for the four unknowns x , y , z , and w yields

$$x = 3.656 \quad y = 0.2086 \quad z = 0.8162 \quad w = 0.1591$$

Thus the equilibrium composition is

The equilibrium constant of the reaction $N_2 \rightleftharpoons 2N$ at 3000 K is $\ln K_p = -22.359$, which is much smaller than the K_p values of the reactions considered. Therefore, it is reasonable to assume that no N will be present in the equilibrium mixture.

16-48E Two chemical reactions are occurring in air. The equilibrium composition at a specified temperature is to be determined.

Assumptions 1 The equilibrium composition consists of O₂, N₂, O, and NO. 2 The constituents of the mixture are ideal gases.

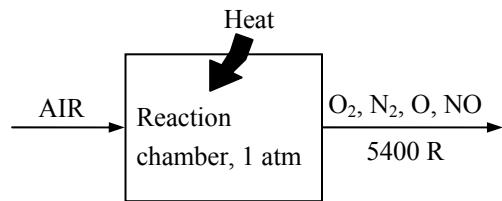

Analysis The reaction equation during this process can be expressed as

Mass balances for nitrogen and oxygen yield

$$\text{N balance: } 7.52 = 2x + y \quad (1)$$

$$\text{O balance: } 2 = y + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at $T = 5400 \text{ R} = 3000 \text{ K}$ are determined from Table A-28 to be

$$\ln K_{P1} = -2.114 \longrightarrow K_{P1} = 0.12075$$

$$\ln K_{P2} = -4.357 \longrightarrow K_{P2} = 0.01282$$

The K_p relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

$$K_{P2} = \frac{N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{O}} - \nu_{\text{O}_2}}$$

where $N_{\text{total}} = N_{\text{N}_2} + N_{\text{NO}} + N_{\text{O}_2} + N_{\text{O}} = x + y + z + w$

Substituting,

$$0.12075 = \frac{y}{x^{0.5} z^{0.5}} \left(\frac{1}{x + y + z + w} \right)^{1-0.5-0.5} \quad (3)$$

$$0.01282 = \frac{w^2}{z} \left(\frac{1}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 3.658 \quad y = 0.2048 \quad z = 0.7868 \quad w = 0.2216$$

Thus the equilibrium composition is

The equilibrium constant of the reaction $\text{N}_2 \rightleftharpoons 2\text{N}$ at 5400 R is $\ln K_p = -22.359$, which is much smaller than the K_p values of the reactions considered. Therefore, it is reasonable to assume that no N will be present in the equilibrium mixture.

14-49E Problem 16-48E is reconsidered. Using EES (or other) software, the equilibrium solution is to be obtained by minimizing the Gibbs function by using the optimization capabilities built into EES. This solution technique is to be compared with that used in the previous problem.

Analysis The problem is solved using EES, and the solution is given below.

"This example illustrates how EES can be used to solve multi-reaction chemical equilibria problems by directly minimizing the Gibbs function.

Two of the four coefficients, a, b, c, and d, are found by minimizing the Gibbs function at a total pressure of 1 atm and a temperature of 5400 R. The other two are found from mass balances.

The equilibrium solution can be found by applying the Law of Mass Action to two simultaneous equilibrium reactions or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, select MinMax from the Calculate menu. There are four compounds present in the products subject to two elemental balances, so there are two degrees of freedom. Minimize Gibbs with respect to two molar quantities such as coefficients b and d. The equilibrium mole numbers of each specie will be determined and displayed in the Solution window.

Minimizing the Gibbs function to find the equilibrium composition requires good initial guesses."

Discussion The equilibrium composition in the above table are based on the reaction in which the reactants are 0.21 kmol O_2 and 0.79 kmol N_2 . If you multiply the equilibrium composition mole numbers above with 4.76, you will obtain equilibrium composition for the reaction in which the reactants are 1 kmol O_2 and 3.76 kmol N_2 . This is the case in problem 16-43E.

16-50 Water vapor is heated during a steady-flow process. The rate of heat supply for a specified exit temperature is to be determined for two cases.

Assumptions 1 The equilibrium composition consists of H₂O, OH, O₂, and H₂. **2** The constituents of the mixture are ideal gases.

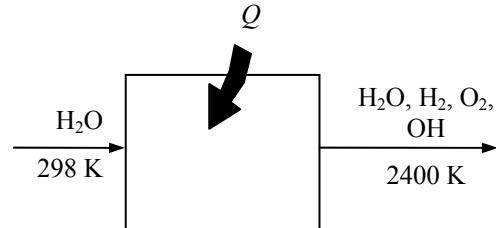

Analysis (a) Assuming some H₂O dissociates into H₂, O₂, and O, the dissociation equation can be written as

Mass balances for hydrogen and oxygen yield

$$\text{H balance: } 2 = 2x + 2y + w \quad (1)$$

$$\text{O balance: } 1 = x + z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_P relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 2400 K are determined from Table A-28 to be

$$\ln K_{P1} = -5.619 \longrightarrow K_{P1} = 0.003628$$

$$\ln K_{P2} = -5.832 \longrightarrow K_{P2} = 0.002932$$

The K_P relations for these three simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

$$K_{P2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

where

$$N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.003628 = \frac{(y)(z)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.002932 = \frac{(w)(y)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 0.960 \quad y = 0.03204 \quad z = 0.01205 \quad w = 0.01588$$

Thus the balanced equation for the dissociation reaction is

The heat transfer for this dissociation process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ with $W = 0$,

$$Q_{\text{in}} = \sum N_P \left(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ \right)_P - \sum N_R \left(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ \right)_R$$

Assuming the O₂ and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{3000\text{ K}}$ kJ/kmol
H ₂ O	-241,820	9904	103,508
H ₂	0	8468	75,383
O ₂	0	8682	83,174
OH	39,460	9188	77,015

Substituting,

$$\begin{aligned} Q_{in} &= 0.960(-241,820 + 103,508 - 9904) \\ &\quad + 0.03204(0 + 75,383 - 8468) \\ &\quad + 0.01205(0 + 83,174 - 8682) \\ &\quad + 0.01588(39,460 + 77,015 - 9188) - (-241,820) \\ &= 103,380 \text{ kJ/kmol H}_2\text{O} \end{aligned}$$

The mass flow rate of H₂O can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.6 \text{ kg/min}}{18 \text{ kg/kmol}} = 0.03333 \text{ kmol/min}$$

Thus,

$$\dot{Q}_{in} = \dot{N} \times Q_{in} = (0.03333 \text{ kmol/min})(103,380 \text{ kJ/kmol}) = \mathbf{3446 \text{ kJ/min}}$$

(b) If no dissociation takes place, then the process involves no chemical reactions and the heat transfer can be determined from the steady-flow energy balance for nonreacting systems to be

$$\begin{aligned} \dot{Q}_{in} &= \dot{m}(h_2 - h_1) = \dot{N}(\bar{h}_2 - \bar{h}_1) \\ &= (0.03333 \text{ kmol/min})(103,508 - 9904) \text{ kJ/kmol} \\ &= \mathbf{3120 \text{ kJ/min}} \end{aligned}$$

16-51 Problem 16-50 is reconsidered. The effect of the final temperature on the rate of heat supplied for the two cases is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

16-52 Ethyl alcohol C_2H_5OH (gas) is burned in a steady-flow adiabatic combustion chamber with 40 percent excess air. The adiabatic flame temperature of the products is to be determined and the adiabatic flame temperature as a function of the percent excess air is to be plotted.

Analysis The complete combustion reaction in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The oxygen balance gives

$$1 + (1+Ex)a_{th} \times 2 = 2 \times 2 + 3 \times 1 + (Ex)(a_{th}) \times 2$$

The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

$$\text{Carbon balance: } 2 = a + b$$

$$\text{Hydrogen balance: } 6 = 2d \longrightarrow d = 3$$

$$\text{Oxygen balance: } 1 + (1+Ex)a_{th} \times 2 = a \times 2 + b + d + e \times 2 + g$$

$$\text{Nitrogen balance: } (1+Ex)a_{th} \times 3.76 \times 2 = f \times 2 + g$$

Solving the above equations, we find the coefficients to be

$$Ex = 0.4, a_{th} = 3, a = 1.995, b = 0.004712, d = 3, e = 1.17, f = 15.76, g = 0.06428$$

Then, we write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 1.995 + 0.004712 + 3 + 1.17 + 15.76 = 21.99$$

The first assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_{p1} = \exp\left(\frac{-\Delta G_1^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right)$$

$$\text{Where } \Delta G_1^*(T_{\text{prod}}) = \nu_{CO} \bar{g}_{CO}^*(T_{\text{prod}}) + \nu_{O2} \bar{g}_{O2}^*(T_{\text{prod}}) - \nu_{CO2} \bar{g}_{CO2}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{CO}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{CO}$$

$$\bar{g}_{O2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{O2}$$

$$\bar{g}_{CO2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{CO2}$$

The equilibrium constant is also given by

$$K_{p1} = \frac{be^{0.5}}{a} \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{(0.004712)(1.17)^{0.5}}{1.995} \left(\frac{1}{21.99} \right)^{0.5} = 0.0005447$$

The second assumed equilibrium reaction is

Also, for this reaction, we have

$$\bar{g}_{\text{NO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{NO}}$$

$$\bar{g}_{\text{N}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{N}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\Delta G_2^*(T_{\text{prod}}) = \nu_{\text{NO}} \bar{g}_{\text{NO}}^*(T_{\text{prod}}) - \nu_{\text{N}_2} \bar{g}_{\text{N}_2}^*(T_{\text{prod}}) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}})$$

$$K_{p2} = \exp\left(\frac{-\Delta G_2^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right)$$

$$K_{p2} = \left(\frac{P}{N_{\text{tot}}}\right)^{1-0.5-0.5} \frac{g}{e^{0.5} f^{0.5}} = \left(\frac{1}{21.99}\right)^0 \frac{0.06428}{(1.17)^{0.5} (15.76)^{0.5}} = 0.01497$$

A steady flow energy balance gives

$$H_R = H_P$$

where

$$\begin{aligned} H_R &= \bar{h}_{f_{\text{fuel@25°C}}} + 4.2 \bar{h}_{\text{O}_2@25^\circ\text{C}} + 15.79 \bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= (-235,310 \text{ kJ/kmol}) + 4.2(0) + 15.79(0) = -235,310 \text{ kJ/kmol} \end{aligned}$$

$$H_P = 1.995 \bar{h}_{\text{CO}_2@T_{\text{prod}}} + 0.004712 \bar{h}_{\text{CO}@T_{\text{prod}}} + 3 \bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} + 1.17 \bar{h}_{\text{O}_2@T_{\text{prod}}} + 15.76 \bar{h}_{\text{N}_2@T_{\text{prod}}} + 0.06428 \bar{h}_{\text{NO}@T_{\text{prod}}}$$

Solving the energy balance equation using EES, we obtain the adiabatic flame temperature

$$T_{\text{prod}} = 1901 \text{ K}$$

The copy of entire EES solution including parametric studies is given next:

Variations of K_p with Temperature

16-53C It enables us to determine the enthalpy of reaction \bar{h}_R from a knowledge of equilibrium constant K_P .

16-54C At 2000 K since combustion processes are exothermic, and exothermic reactions are more complete at lower temperatures.

16-55 The \bar{h}_R value for the dissociation process $O_2 \rightleftharpoons 2O$ at a specified temperature is to be determined using enthalpy and K_P data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The dissociation equation of O_2 can be expressed as

The \bar{h}_R of the dissociation process of O_2 at 3100 K is the amount of energy absorbed or released as one kmol of O_2 dissociates in a steady-flow combustion chamber at a temperature of 3100 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O_2 and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2900\text{ K}}$ kJ/kmol
O	249,190	6852	65,520
O_2	0	8682	110,784

Substituting,

$$\begin{aligned}\bar{h}_R &= 2(249,190 + 65,520 - 6852) - 1(0 + 110,784 - 8682) \\ &= \mathbf{513,614\text{ kJ/kmol}}\end{aligned}$$

(b) The \bar{h}_R value at 3100 K can be estimated by using K_P values at 3000 K and 3200 K (the closest two temperatures to 3100 K for which K_P data are available) from Table A-28,

$$\begin{aligned}\ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ -3.072 - (-4.357) &\cong \frac{\bar{h}_R}{8.314 \text{ kJ/kmol}\cdot\text{K}} \left(\frac{1}{3000 \text{ K}} - \frac{1}{3200 \text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{512,808\text{ kJ/kmol}}\end{aligned}$$

16-56 The \bar{h}_R at a specified temperature is to be determined using the enthalpy and K_P data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The complete combustion equation of CO can be expressed as

The \bar{h}_R of the combustion process of CO at 2200 K is the amount of energy released as one kmol of CO is burned in a steady-flow combustion chamber at a temperature of 2200 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO, O₂ and CO₂ to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298\text{ K}}$	$\bar{h}_{2200\text{ K}}$
	kJ/kmol	kJ/kmol	kJ/kmol
CO ₂	-393,520	9364	112,939
CO	-110,530	8669	72,688
O ₂	0	8682	75,484

Substituting,

$$\begin{aligned}\bar{h}_R &= 1(-393,520 + 112,939 - 9364) \\ &\quad - 1(-110,530 + 72,688 - 8669) \\ &\quad - 0.5(0 + 75,484 - 8682) \\ &= \mathbf{-276,835 \text{ kJ / kmol}}\end{aligned}$$

(b) The \bar{h}_R value at 2200 K can be estimated by using K_P values at 2000 K and 2400 K (the closest two temperatures to 2200 K for which K_P data are available) from Table A-28,

$$\begin{aligned}\ln \frac{K_{P2}}{K_{P1}} &\approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \text{ or } \ln K_{P2} - \ln K_{P1} \approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ 3.860 - 6.635 &\approx \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2000 \text{ K}} - \frac{1}{2400 \text{ K}} \right) \\ \bar{h}_R &\approx \mathbf{-276,856 \text{ kJ/kmol}}\end{aligned}$$

16-57E The \bar{h}_R at a specified temperature is to be determined using the enthalpy and K_P data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The complete combustion equation of CO can be expressed as

The \bar{h}_R of the combustion process of CO at 3960 R is the amount of energy released as one kmol of H₂ is burned in a steady-flow combustion chamber at a temperature of 3960 R, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO, O₂ and CO₂ to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{ R}}$ Btu/lbmol	$\bar{h}_{3960\text{ R}}$ Btu/lbmol
CO ₂	-169,300	4027.5	48,647
CO	-47,540	3725.1	31,256.5
O ₂	0	3725.1	32,440.5

Substituting,

$$\begin{aligned}\bar{h}_R &= 1(-169,300 + 48,647 - 4027.5) \\ &\quad - 1(-47,540 + 31,256.5 - 3725.1) \\ &\quad - 0.5(0 + 32,440.5 - 3725.1) \\ &= \mathbf{-119,030 \text{ Btu / lbmol}}\end{aligned}$$

(b) The \bar{h}_R value at 3960 R can be estimated by using K_P values at 3600 R and 4320 R (the closest two temperatures to 3960 R for which K_P data are available) from Table A-28,

$$\begin{aligned}\ln \frac{K_{P2}}{K_{P1}} &\approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \text{ or } \ln K_{P2} - \ln K_{P1} \approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ 3.860 - 6.635 &\approx \frac{\bar{h}_R}{1.986 \text{ Btu/lbmol} \cdot \text{R}} \left(\frac{1}{3600 \text{ R}} - \frac{1}{4320 \text{ R}} \right) \\ \bar{h}_R &\approx \mathbf{-119,041 \text{ Btu/lbmol}}\end{aligned}$$

16-58 The K_P value of the combustion process $\text{H}_2 + 1/2\text{O}_2 \rightleftharpoons \text{H}_2\text{O}$ is to be determined at a specified temperature using \bar{h}_R data and K_P value.

Assumptions Both the reactants and products are ideal gases.

Analysis The \bar{h}_R and K_P data are related to each other by

$$\ln \frac{K_{P2}}{K_{P1}} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$$

The \bar{h}_R of the specified reaction at 3000 K is the amount of energy released as one kmol of H_2 is burned in a steady-flow combustion chamber at a temperature of 3000 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the H_2O , H_2 and O_2 to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{3000\text{K}}$ kJ/kmol
H_2O	-241,820	9904	136,264
H_2	0	8468	97,211
O_2	0	8682	106,780

Substituting,

$$\begin{aligned}\bar{h}_R &= 1(-241,820 + 136,264 - 9904) \\ &\quad - 1(0 + 97,211 - 8468) \\ &\quad - 0.5(0 + 106,780 - 8682) \\ &= -253,250 \text{ kJ/kmol}\end{aligned}$$

The K_P value at 3200 K can be estimated from the equation above by using this \bar{h}_R value and the K_P value at 2800 K which is $\ln K_{P1} = 3.812$ or $K_{P1} = 45.24$,

$$\ln(K_{P2}/45.24) \cong \frac{-253,250 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2800 \text{ K}} - \frac{1}{3200 \text{ K}} \right)$$

$$\ln K_{P2} = 2.452 \quad (\text{Table A - 28 : } \ln K_{P2} = 2.451)$$

or

$$K_{P2} = 11.6$$

16-59 The \bar{h}_R value for the dissociation process $\text{CO}_2 \rightleftharpoons \text{CO} + \frac{1}{2}\text{O}_2$ at a specified temperature is to be determined using enthalpy and K_p data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The dissociation equation of CO_2 can be expressed as

The \bar{h}_R of the dissociation process of CO_2 at 2200 K is the amount of energy absorbed or released as one kmol of CO_2 dissociates in a steady-flow combustion chamber at a temperature of 2200 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO, O₂ and CO₂ to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2200\text{ K}}$ kJ/kmol
CO ₂	-393,520	9364	112,939
CO	-110,530	8669	72,688
O ₂	0	8682	75,484

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-110,530 + 72,688 - 8669) \\ &\quad + 0.5(0 + 75,484 - 8682) \\ &\quad - 1(-393,520 + 112,939 - 9364) \\ &= \mathbf{276,835 \text{ kJ / kmol}} \end{aligned}$$

(b) The \bar{h}_R value at 2200 K can be estimated by using K_p values at 2000 K and 2400 K (the closest two temperatures to 2200 K for which K_p data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ -3.860 - (-6.635) &\cong \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2000 \text{ K}} - \frac{1}{2400 \text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{276,856 \text{ kJ/kmol}} \end{aligned}$$

16-60 The enthalpy of reaction for the equilibrium reaction $\text{CH}_4 + 2\text{O}_2 = \text{CO}_2 + 2\text{H}_2\text{O}$ at 2000 K is to be estimated using enthalpy data and equilibrium constant, K_p data.

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At $T_1 = 2000 - 10 = 1990$ K:

$$\begin{aligned}\Delta G_1^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_1) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_1) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T_1) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_1) \\ &= 1(-917,176) + 2(-695,638) - 1(-559,718) - 2(-475,399) \\ &= -797,938 \text{ kJ/kmol}\end{aligned}$$

At $T_2 = 2000 + 10 = 2010$ K:

$$\begin{aligned}\Delta G_2^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_2) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_2) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T_2) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_2) \\ &= 1(-923,358) + 2(-700,929) - 1(-565,835) - 2(-480,771) \\ &= -797,839 \text{ kJ/kmol}\end{aligned}$$

The Gibbs functions are obtained from enthalpy and entropy properties using EES. Substituting,

$$K_{p1} = \exp\left(-\frac{-797,938 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(1990 \text{ K})}\right) = 8.820 \times 10^{20}$$

$$K_{p2} = \exp\left(-\frac{-797,839 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2010 \text{ K})}\right) = 5.426 \times 10^{20}$$

The enthalpy of reaction is determined by using the integrated van't Hoff equation:

$$\begin{aligned}\ln\left(\frac{K_{p2}}{K_{p1}}\right) &= \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ \ln\left(\frac{5.426 \times 10^{20}}{8.820 \times 10^{20}}\right) &= \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{1990 \text{ K}} - \frac{1}{2010 \text{ K}} \right) \longrightarrow \bar{h}_R = -807,752 \text{ kJ/kmol}\end{aligned}$$

The enthalpy of reaction can also be determined from an energy balance to be

$$\bar{h}_R = H_P - H_R$$

where

$$H_R = 1\bar{h}_{\text{CH}_4 @ 2000 \text{ K}} + 2\bar{h}_{\text{O}_2 @ 2000 \text{ K}} = 48,947 + 2(59,193) = 167,333 \text{ kJ/kmol}$$

$$H_P = 1\bar{h}_{\text{CO}_2 @ 2000 \text{ K}} + 2\bar{h}_{\text{H}_2\text{O} @ 2000 \text{ K}} = (-302,094) + 2(-169,162) = -640,419 \text{ kJ/kmol}$$

The enthalpies are obtained from EES. Substituting,

$$\bar{h}_R = H_P - H_R = (-640,419) - (167,333) = -807,752 \text{ kJ/kmol}$$

which is identical to the value obtained using K_p data.

Phase Equilibrium

16-61C No. Because the specific gibbs function of each phase will not be affected by this process; i.e., we will still have $g_f = g_g$.

16-62C Yes. Because the number of independent variables for a two-phase ($PH=2$), two-component ($C=2$) mixture is, from the phase rule,

$$IV = C - PH + 2 = 2 - 2 + 2 = 2$$

Therefore, two properties can be changed independently for this mixture. In other words, we can hold the temperature constant and vary the pressure and still be in the two-phase region. Notice that if we had a single component ($C=1$) two phase system, we would have $IV=1$, which means that fixing one independent property automatically fixes all the other properties.

11-63C Using solubility data of a solid in a specified liquid, the mass fraction w of the solid A in the liquid at the interface at a specified temperature can be determined from

$$mf_A = \frac{m_{\text{solid}}}{m_{\text{solid}} + m_{\text{liquid}}}$$

where m_{solid} is the maximum amount of solid dissolved in the liquid of mass m_{liquid} at the specified temperature.

11-64C The molar concentration C_i of the gas species i in the solid at the interface $C_{i, \text{solid side}}(0)$ is proportional to the *partial pressure* of the species i in the gas $P_{i, \text{gas side}}(0)$ on the gas side of the interface, and is determined from

$$C_{i, \text{solid side}}(0) = S \times P_{i, \text{gas side}}(0) \quad (\text{kmol/m}^3)$$

where S is the *solubility* of the gas in that solid at the specified temperature.

11-65C Using Henry's constant data for a gas dissolved in a liquid, the mole fraction of the gas dissolved in the liquid at the interface at a specified temperature can be determined from Henry's law expressed as

$$\gamma_{i, \text{liquid side}}(0) = \frac{P_{i, \text{gas side}}(0)}{H}$$

where H is *Henry's constant* and $P_{i, \text{gas side}}(0)$ is the partial pressure of the gas i at the gas side of the interface. This relation is applicable for dilute solutions (gases that are weakly soluble in liquids).

16-66E The maximum partial pressure of the water evaporated into the air as it emerges from a porous media is to be determined.

Assumptions The air and water-air solution behave as ideal solutions so that Raoult's law may be used.

Analysis The saturation temperature of water at 70°F is

$$P_{\text{sat}@70^{\circ}\text{F}} = 0.36334 \text{ psia}$$

Since the mole fraction of the air in the liquid water is essentially zero,

$$P_{v,\text{max}} = 1 \times P_{\text{sat}@70^{\circ}\text{F}} = \mathbf{0.36334 \text{ psia}}$$

16-67 The number of independent properties needed to fix the state of a mixture of oxygen and nitrogen in the gas phase is to be determined.

Analysis In this case the number of components is $C = 2$ and the number of phases is $\text{PH} = 1$. Then the number of independent variables is determined from the phase rule to be

$$\text{IV} = C - \text{PH} + 2 = 2 - 1 + 2 = 3$$

Therefore, three independent properties need to be specified to fix the state. They can be temperature, the pressure, and the mole fraction of one of the gases.

16-68 It is to be shown that a saturated liquid-vapor mixture of refrigerant-134a at -20°C satisfies the criterion for phase equilibrium.

Analysis Using the definition of Gibbs function and enthalpy and entropy data from Table A-11,

$$g_f = h_f - Ts_f = (25.49 \text{ kJ/kg}) - (253.15 \text{ K})(0.10463 \text{ kJ/kg} \cdot \text{K}) = -0.9967 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (238.41 \text{ kJ/kg}) - (253.15 \text{ K})(0.94564 \text{ kJ/kg} \cdot \text{K}) = -0.9842 \text{ kJ/kg}$$

which are sufficiently close. Therefore, the criterion for phase equilibrium is satisfied.

16-69 It is to be shown that a mixture of saturated liquid water and saturated water vapor at 300 kPa satisfies the criterion for phase equilibrium.

Analysis The saturation temperature at 300 kPa is 406.7 K. Using the definition of Gibbs function and enthalpy and entropy data from Table A-5,

$$g_f = h_f - Ts_f = (561.43 \text{ kJ/kg}) - (406.7 \text{ K})(1.6717 \text{ kJ/kg} \cdot \text{K}) = -118.5 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (2724.9 \text{ kJ/kg}) - (406.7 \text{ K})(6.9917 \text{ kJ/kg} \cdot \text{K}) = -118.6 \text{ kJ/kg}$$

which are practically same. Therefore, the criterion for phase equilibrium is satisfied.

16-70 The values of the Gibbs function for saturated refrigerant-134a at 280 kPa are to be calculated.

Analysis The saturation temperature of R-134a at 280 kPa is -1.25°C (Table A-12). Obtaining other properties from Table A-12, the Gibbs function for the liquid phase is,

$$g_f = h_f - Ts_f = 50.18 \text{ kJ/kg} - (-1.25 + 273.15 \text{ K})(0.19829 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.74 \text{ kJ/kg}}$$

For the vapor phase,

$$g_g = h_g - Ts_g = 249.72 \text{ kJ/kg} - (-1.25 + 273.15 \text{ K})(0.93210 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.72 \text{ kJ/kg}}$$

R-134a
280 kPa
 $x = 0.7$

The results agree and demonstrate that phase equilibrium exists.

16-71E The values of the Gibbs function for saturated steam at 300°F as a saturated liquid, saturated vapor, and a mixture of liquid and vapor are to be calculated.

Analysis Obtaining properties from Table A-4E, the Gibbs function for the liquid phase is,

$$g_f = h_f - Ts_f = 269.73 \text{ Btu/lbm} - (759.67 \text{ R})(0.43720 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{-62.40 \text{ Btu/lbm}}$$

Steam
 300°F

For the vapor phase,

$$g_g = h_g - Ts_g = 1180.0 \text{ Btu/lbm} - (759.67 \text{ R})(1.6354 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{-62.36 \text{ Btu/lbm}}$$

For the saturated mixture with a quality of 60%,

$$h = h_f + xh_{fg} = 269.73 \text{ Btu/lbm} + (0.60)(910.24 \text{ Btu/lbm}) = 815.87 \text{ Btu/lbm}$$

$$s = s_f + xs_{fg} = 0.43720 \text{ Btu/lbm} \cdot \text{R} + (0.60)(1.19818 \text{ Btu/lbm} \cdot \text{R}) = 1.1561 \text{ Btu/lbm} \cdot \text{R}$$

$$g = h - Ts = 815.87 \text{ Btu/lbm} - (759.67 \text{ R})(1.1561 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{-62.38 \text{ Btu/lbm}}$$

The results agree and demonstrate that phase equilibrium exists.

16-72 A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The pressure of ammonia is to be determined for two compositions of the liquid phase.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Analysis According to Raoult's law, when the mole fraction of the ammonia liquid is 20%,

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.20(615.3 \text{ kPa}) = \mathbf{123.1 \text{ kPa}}$$

When the mole fraction of the ammonia liquid is 80%,

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.80(615.3 \text{ kPa}) = \mathbf{492.2 \text{ kPa}}$$

$\text{H}_2\text{O} + \text{NH}_3$
 10°C

16-73 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture, the composition of each phase at a specified temperature and pressure is to be determined.

Analysis From the equilibrium diagram (Fig. 16-21) we read

Liquid: 65% N₂ and 35% O₂

Vapor: 90% N₂ and 10% O₂

16-74 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the temperature is to be determined for a specified composition of the vapor phase.

Analysis From the equilibrium diagram (Fig. 16-21) we read **T = 82 K**.

16-75 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the temperature is to be determined for a specified composition of the nitrogen.

Properties The molar masses of O₂ is 32 kg/kmol and that of N₂ is 28 kg/kmol (Table A-1).

Analysis For 100 kg of liquid phase, the mole numbers are

$$N_{f,O_2} = \frac{m_{f,O_2}}{M_{O_2}} = \frac{40 \text{ kg}}{32 \text{ kg/kmol}} = 1.25 \text{ kmol}$$

$$N_{f,N_2} = \frac{m_{f,N_2}}{M_{N_2}} = \frac{60 \text{ kg}}{28 \text{ kg/kmol}} = 2.143 \text{ kmol}$$

$$N_{f,\text{total}} = 1.25 + 2.143 = 3.393 \text{ kmol}$$

The mole fractions in the liquid phase are

$$\gamma_{f,O_2} = \frac{N_{f,O_2}}{N_{f,\text{total}}} = \frac{1.25 \text{ kmol}}{3.393 \text{ kmol}} = 0.3684$$

$$\gamma_{f,N_2} = \frac{N_{f,N_2}}{N_{f,\text{total}}} = \frac{2.143 \text{ kmol}}{3.393 \text{ kmol}} = 0.6316$$

From the equilibrium diagram (Fig. 16-21) we read **T = 80.5 K**.

16-76 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the mass of the oxygen in the liquid and gaseous phases is to be determined for a specified composition of the mixture.

Properties The molar masses of O₂ is 32 kg/kmol and that of N₂ is 28 kg/kmol (Table A-1).

Analysis From the equilibrium diagram (Fig. 16-21) at T = 84 K, the oxygen mole fraction in the vapor phase is 34% and that in the liquid phase is 70%. That is,

$$y_{f,O_2} = 0.70 \quad \text{and} \quad y_{g,O_2} = 0.34$$

The mole numbers are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{30 \text{ kg}}{32 \text{ kg/kmol}} = 0.9375 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{40 \text{ kg}}{28 \text{ kg/kmol}} = 1.429 \text{ kmol}$$

$$N_{\text{total}} = 0.9375 + 1.429 = 2.366 \text{ kmol}$$

The total number of moles in this system is

$$N_f + N_g = 2.366 \quad (1)$$

The total number of moles of oxygen in this system is

$$0.7N_f + 0.34N_g = 0.9375 \quad (2)$$

Solving equations (1) and (2) simultaneously, we obtain

$$N_f = 0.3696$$

$$N_g = 1.996$$

Then, the mass of oxygen in the liquid and vapor phases is

$$m_{f,O_2} = y_{f,O_2} N_f M_{O_2} = (0.7)(0.3696 \text{ kmol})(32 \text{ kg/kmol}) = \mathbf{8.28 \text{ kg}}$$

$$m_{g,O_2} = y_{g,O_2} N_g M_{O_2} = (0.34)(1.996 \text{ kmol})(32 \text{ kg/kmol}) = \mathbf{21.72 \text{ kg}}$$

16-77 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the total mass of the liquid phase is to be determined.

Properties The molar masses of O₂ is 32 kg/kmol and that of N₂ is 28 kg/kmol (Table A-1).

Analysis From the equilibrium diagram (Fig. 16-21) at T = 84 K, the oxygen mole fraction in the vapor phase is 34% and that in the liquid phase is 70%. That is,

$$y_{f,O_2} = 0.70 \quad \text{and} \quad y_{g,O_2} = 0.34$$

Also,

$$y_{f,N_2} = 0.30 \quad \text{and} \quad y_{g,N_2} = 0.66$$

The mole numbers are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{30 \text{ kg}}{32 \text{ kg/kmol}} = 0.9375 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{40 \text{ kg}}{28 \text{ kg/kmol}} = 1.429 \text{ kmol}$$

$$N_{\text{total}} = 0.9375 + 1.429 = 2.366 \text{ kmol}$$

The total number of moles in this system is

$$N_f + N_g = 2.366 \quad (1)$$

The total number of moles of oxygen in this system is

$$0.7N_f + 0.34N_g = 0.9375 \quad (2)$$

Solving equations (1) and (2) simultaneously, we obtain

$$N_f = 0.3696$$

$$N_g = 1.996$$

The total mass of liquid in the mixture is then

$$\begin{aligned} m_{f,\text{total}} &= m_{f,O_2} + m_{f,N_2} \\ &= y_{f,O_2}N_f M_{O_2} + y_{f,N_2}N_g M_{N_2} \\ &= (0.7)(0.3696 \text{ kmol})(32 \text{ kg/kmol}) + (0.3)(0.3696 \text{ kmol})(28 \text{ kg/kmol}) \\ &= \mathbf{11.38 \text{ kg}} \end{aligned}$$

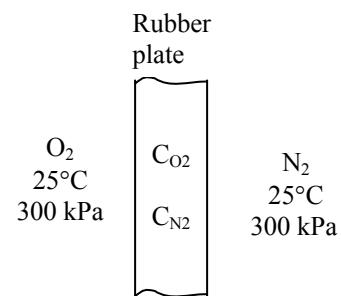

16-78 A rubber wall separates O₂ and N₂ gases. The molar concentrations of O₂ and N₂ in the wall are to be determined.

Assumptions The O₂ and N₂ gases are in phase equilibrium with the rubber wall.

Properties The molar mass of oxygen and nitrogen are 32.0 and 28.0 kg/kmol, respectively (Table A-1). The solubility of oxygen and nitrogen in rubber at 298 K are 0.00312 and 0.00156 kmol/m³·bar, respectively (Table 16-3).

Analysis Noting that 300 kPa = 3 bar, the molar densities of oxygen and nitrogen in the rubber wall are determined to be

$$\begin{aligned} C_{O_2, \text{solid side}}(0) &= S \times P_{O_2, \text{gas side}} \\ &= (0.00312 \text{ kmol/m}^3 \cdot \text{bar})(3 \text{ bar}) \\ &= \mathbf{0.00936 \text{ kmol/m}^3} \\ C_{N_2, \text{solid side}}(0) &= S \times P_{N_2, \text{gas side}} \\ &= (0.00156 \text{ kmol/m}^3 \cdot \text{bar})(3 \text{ bar}) \\ &= \mathbf{0.00468 \text{ kmol/m}^3} \end{aligned}$$

That is, there will be 0.00936 kmol of O₂ and 0.00468 kmol of N₂ gas in each m³ volume of the rubber wall.

16-79 A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The composition of the vapor phase is given. The composition of the liquid phase is to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

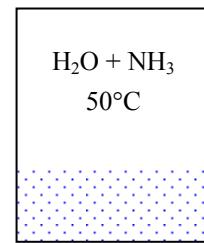

Properties At 50°C, $P_{\text{sat},H_2O} = 12.352 \text{ kPa}$ and $P_{\text{sat},NH_3} = 2033.5 \text{ kPa}$.

Analysis We have $y_{g,H_2O} = 1\%$ and $y_{g,NH_3} = 99\%$. For an ideal two-phase mixture we have

$$\begin{aligned} y_{g,H_2O}P_m &= y_{f,H_2O}P_{\text{sat},H_2O}(T) \\ y_{g,NH_3}P_m &= y_{f,NH_3}P_{\text{sat},NH_3}(T) \\ y_{f,H_2O} + y_{f,NH_3} &= 1 \end{aligned}$$

Solving for y_{f,H_2O} ,

$$y_{f,H_2O} = \frac{y_{g,H_2O}P_{\text{sat},NH_3}}{y_{g,NH_3}P_{\text{sat},H_2O}}(1 - y_{f,H_2O}) = \frac{(0.01)(2033.5 \text{ kPa})}{(0.99)(12.352 \text{ kPa})}(1 - y_{f,H_2O})$$

It yields

$$y_{f,H_2O} = \mathbf{0.624} \text{ and } y_{f,NH_3} = \mathbf{0.376}$$

16-80 A mixture of water and ammonia is considered. The mole fractions of the ammonia in the liquid and vapor phases are to be determined.

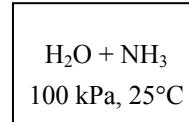

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 25°C, $P_{\text{sat,H}_2\text{O}} = 3.1698 \text{ kPa}$ and $P_{\text{sat,NH}_3} = 1003.5 \text{ kPa}$ (Tables A-4).

Analysis According to Raoult's law, the partial pressures of ammonia and water in the vapor phase are given by

$$P_{g,\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat,NH}_3} = \frac{N_{f,\text{NH}_3}}{N_{f,\text{NH}_3} + N_{f,\text{H}_2\text{O}}} (1003.5 \text{ kPa})$$

$$P_{g,\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = \frac{N_{f,\text{H}_2\text{O}}}{N_{f,\text{H}_2\text{O}} + N_{f,\text{NH}_3}} (3.1698 \text{ kPa})$$

The sum of these two partial pressures must equal the total pressure of the vapor mixture. In terms of $x = \frac{N_{f,\text{H}_2\text{O}}}{N_{f,\text{NH}_3}}$, this sum is

$$\frac{1003.5}{x+1} + \frac{3.1698x}{x+1} = 100$$

Solving this expression for x gives

$$x = 9.331 \text{ kmol H}_2\text{O/kmol NH}_3$$

In the vapor phase, the partial pressure of the ammonia vapor is

$$P_{g,\text{NH}_3} = \frac{1003.5}{x+1} = \frac{1003.5}{9.331+1} = 97.13 \text{ kPa}$$

The mole fraction of ammonia in the vapor phase is then

$$y_{g,\text{NH}_3} = \frac{P_{g,\text{NH}_3}}{P} = \frac{97.13 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.9713}$$

According to Raoult's law,

$$y_{f,\text{NH}_3} = \frac{P_{g,\text{NH}_3}}{P_{\text{sat,NH}_3}} = \frac{97.13 \text{ kPa}}{1003.5 \text{ kPa}} = \mathbf{0.0968}$$

16-81 An ammonia-water absorption refrigeration unit is considered. The operating pressures in the generator and absorber, and the mole fractions of the ammonia in the strong liquid mixture being pumped from the absorber and the weak liquid solution being drained from the generator are to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 0°C, $P_{\text{sat},\text{H}_2\text{O}} = 0.6112 \text{ kPa}$ and at 46°C, $P_{\text{sat},\text{H}_2\text{O}} = 10.10 \text{ kPa}$ (Table A-4). The saturation pressures of ammonia at the same temperatures are given to be 430.6 kPa and 1830.2 kPa, respectively.

Analysis According to Raoult's law, the partial pressures of ammonia and water are given by

$$\begin{aligned} P_{g,\text{NH}_3} &= y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3} \\ P_{g,\text{H}_2\text{O}} &= y_{f,\text{H}_2\text{O}} P_{\text{sat},\text{H}_2\text{O}} = (1 - y_{f,\text{NH}_3}) P_{\text{sat},\text{H}_2\text{O}} \end{aligned}$$

Using Dalton's partial pressure model for ideal gas mixtures, the mole fraction of the ammonia in the vapor mixture is

$$\begin{aligned} y_{g,\text{NH}_3} &= \frac{y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}}{y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat},\text{H}_2\text{O}}} \\ 0.96 &= \frac{430.6 y_{f,\text{NH}_3}}{430.6 y_{f,\text{NH}_3} + 0.6112(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.03294} \end{aligned}$$

Then,

$$\begin{aligned} P &= y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat},\text{H}_2\text{O}} \\ &= (0.03294)(430.6) + (1 - 0.03294)(0.6112) = \mathbf{14.78 \text{ kPa}} \end{aligned}$$

Performing the similar calculations for the regenerator,

$$\begin{aligned} 0.96 &= \frac{1830.2 y_{f,\text{NH}_3}}{1830.2 y_{f,\text{NH}_3} + 10.10(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.1170} \\ P &= (0.1170)(1830.2) + (1 - 0.1170)(10.10) = \mathbf{223.1 \text{ kPa}} \end{aligned}$$

16-82 An ammonia-water absorption refrigeration unit is considered. The operating pressures in the generator and absorber, and the mole fractions of the ammonia in the strong liquid mixture being pumped from the absorber and the weak liquid solution being drained from the generator are to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 6°C, $P_{\text{sat},\text{H}_2\text{O}} = 0.9353 \text{ kPa}$ and at 40°C, $P_{\text{sat},\text{H}_2\text{O}} = 7.3851 \text{ kPa}$ (Table A-4 or EES). The saturation pressures of ammonia at the same temperatures are given to be 534.8 kPa and 1556.7 kPa, respectively.

Analysis According to Raoult's law, the partial pressures of ammonia and water are given by

$$\begin{aligned} P_{g,\text{NH}_3} &= y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3} \\ P_{g,\text{H}_2\text{O}} &= y_{f,\text{H}_2\text{O}} P_{\text{sat},\text{H}_2\text{O}} = (1 - y_{f,\text{NH}_3}) P_{\text{sat},\text{H}_2\text{O}} \end{aligned}$$

Using Dalton's partial pressure model for ideal gas mixtures, the mole fraction of the ammonia in the vapor mixture is

$$\begin{aligned} y_{g,\text{NH}_3} &= \frac{y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}}{y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat},\text{H}_2\text{O}}} \\ 0.96 &= \frac{534.8 y_{f,\text{NH}_3}}{534.8 y_{f,\text{NH}_3} + 0.9353(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.04028} \end{aligned}$$

Then,

$$\begin{aligned} P &= y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat},\text{H}_2\text{O}} \\ &= (0.04028)(534.8) + (1 - 0.04028)(0.9353) = \mathbf{22.44 \text{ kPa}} \end{aligned}$$

Performing the similar calculations for the regenerator,

$$\begin{aligned} 0.96 &= \frac{1556.7 y_{f,\text{NH}_3}}{1556.7 y_{f,\text{NH}_3} + 7.3851(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.1022} \\ P &= (0.1022)(1556.7) + (1 - 0.1022)(7.3851) = \mathbf{165.7 \text{ kPa}} \end{aligned}$$

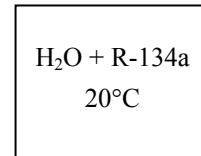

16-83 A liquid mixture of water and R-134a is considered. The mole fraction of the water and R-134a vapor are to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 20°C, $P_{\text{sat,H}_2\text{O}} = 2.3392 \text{ kPa}$ and $P_{\text{sat,R}} = 572.07 \text{ kPa}$ (Tables A-4, A-11). The molar masses of water and R-134a are 18.015 and 102.03 kg/kmol, respectively (Table A-1).

Analysis The mole fraction of the water in the liquid mixture is

$$\begin{aligned} y_{f,\text{H}_2\text{O}} &= \frac{N_{f,\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{\text{mf}_{f,\text{H}_2\text{O}} / M_{\text{H}_2\text{O}}}{(\text{mf}_{f,\text{H}_2\text{O}} / M_{\text{H}_2\text{O}}) + (\text{mf}_{f,\text{R}} / M_{\text{R}})} \\ &= \frac{0.9 / 18.015}{(0.9 / 18.015) + (0.1 / 102.03)} = 0.9808 \end{aligned}$$

According to Raoult's law, the partial pressures of R-134a and water in the vapor mixture are

$$P_{g,\text{R}} = y_{f,\text{R}} P_{\text{sat,R}} = (1 - 0.9808)(572.07 \text{ kPa}) = 10.98 \text{ kPa}$$

$$P_{g,\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (0.9808)(2.3392 \text{ kPa}) = 2.294 \text{ kPa}$$

The total pressure of the vapor mixture is then

$$P_{\text{total}} = P_{g,\text{R}} + P_{g,\text{H}_2\text{O}} = 10.98 + 2.294 = 13.274 \text{ kPa}$$

Based on Dalton's partial pressure model for ideal gases, the mole fractions in the vapor phase are

$$y_{g,\text{H}_2\text{O}} = \frac{P_{g,\text{H}_2\text{O}}}{P_{\text{total}}} = \frac{2.294 \text{ kPa}}{13.274 \text{ kPa}} = \mathbf{0.1728}$$

$$y_{g,\text{R}} = \frac{P_{g,\text{R}}}{P_{\text{total}}} = \frac{10.98 \text{ kPa}}{13.274 \text{ kPa}} = \mathbf{0.8272}$$

16-84 A glass of water is left in a room. The mole fraction of the water vapor in the air and the mole fraction of air in the water are to be determined when the water and the air are in thermal and phase equilibrium.

Assumptions 1 Both the air and water vapor are ideal gases. 2 Air is saturated since the humidity is 100 percent. 3 Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 27°C is 3.568 kPa (Table A-4). Henry's constant for air dissolved in water at 27°C (300 K) is given in Table 16-2 to be $H = 74,000$ bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

Analysis (a) Noting that air is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{\text{sat} @ 27^\circ\text{C}} = 3.568 \text{ kPa} \quad (\text{Table A-4})$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air is determined to be

$$\gamma_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.568 \text{ kPa}}{92 \text{ kPa}} = \mathbf{0.0388}$$

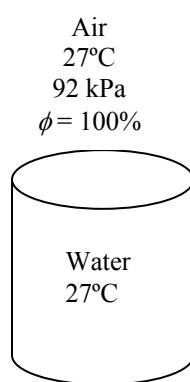

(b) Noting that the total pressure is 92 kPa, the partial pressure of dry air is

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 92 - 3.568 = 88.43 \text{ kPa} = 0.8843 \text{ bar}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$\gamma_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gas side}}}{H} = \frac{0.8843 \text{ bar}}{74,000 \text{ bar}} = \mathbf{1.20 \times 10^{-5}}$$

Discussion The amount of air dissolved in water is very small, as expected.

16-85 A carbonated drink in a bottle is considered. Assuming the gas space above the liquid consists of a saturated mixture of CO₂ and water vapor and treating the drink as a water, determine the mole fraction of the water vapor in the CO₂ gas and the mass of dissolved CO₂ in a 300 ml drink are to be determined when the water and the CO₂ gas are in thermal and phase equilibrium.

Assumptions 1 The liquid drink can be treated as water. 2 Both the CO₂ and the water vapor are ideal gases. 3 The CO₂ gas and water vapor in the bottle from a saturated mixture. 4 The CO₂ is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 27°C is 3.568 kPa (Table A-4). Henry's constant for CO₂ dissolved in water at 27°C (300 K) is given in Table 16-2 to be $H = 1710$ bar. Molar masses of CO₂ and water are 44 and 18 kg/kmol, respectively (Table A-1).

Analysis (a) Noting that the CO₂ gas in the bottle is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{\text{sat@27}^{\circ}\text{C}} = 3.568 \text{ kPa} \quad (\text{more accurate EES value compared to interpolation value from Table A-4})$$

Assuming both CO₂ and vapor to be ideal gases, the mole fraction of water vapor in the CO₂ gas becomes

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.568 \text{ kPa}}{130 \text{ kPa}} = \mathbf{0.0274}$$

(b) Noting that the total pressure is 130 kPa, the partial pressure of CO₂ is

$$P_{\text{CO}_2 \text{ gas}} = P - P_{\text{vapor}} = 130 - 3.568 = 126.4 \text{ kPa} = 1.264 \text{ bar}$$

From Henry's law, the mole fraction of CO₂ in the drink is determined to be

$$y_{\text{CO}_2, \text{liquid side}} = \frac{P_{\text{CO}_2, \text{gas side}}}{H} = \frac{1.264 \text{ bar}}{1710 \text{ bar}} = \mathbf{7.39 \times 10^{-4}}$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{\text{CO}_2, \text{liquid side}} = 1 - 7.39 \times 10^{-4} = 0.9993$$

The mass and mole fractions of a mixture are related to each other by

$$\text{mf}_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO₂ mixture) is

$$M_m = \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{CO}_2} M_{\text{CO}_2} = 0.9993 \times 18.0 + (7.39 \times 10^{-4}) \times 44 = 18.02 \text{ kg / kmol}$$

Then the mass fraction of dissolved CO₂ gas in liquid water becomes

$$\text{mf}_{\text{CO}_2, \text{liquid side}} = y_{\text{CO}_2, \text{liquid side}} (0) \frac{M_{\text{CO}_2}}{M_m} = 7.39 \times 10^{-4} \frac{44}{18.02} = 0.00180$$

Therefore, the mass of dissolved CO₂ in a 300 ml ≈ 300 g drink is

$$m_{\text{CO}_2} = \text{mf}_{\text{CO}_2} m_m = (0.00180)(300 \text{ g}) = \mathbf{0.54 \text{ g}}$$

Review Problems

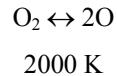

16-86 The equilibrium constant of the dissociation process $O_2 \leftrightarrow 2O$ is given in Table A-28 at different temperatures. The value at a given temperature is to be verified using Gibbs function data.

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\begin{aligned}\Delta G^*(T) &= \nu_O \bar{g}_O^*(T) - \nu_{O_2} \bar{g}_{O_2}^*(T) \\ &= \nu_O (\bar{h} - T\bar{s})_O - \nu_{O_2} (\bar{h} - T\bar{s})_{O_2} \\ &= \nu_O [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_O - \nu_{O_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{O_2} \\ &= 2 \times (249,190 + 42,564 - 6852 - 2000 \times 201.135) \\ &\quad - 1 \times (0 + 67,881 - 8682 - 2000 \times 268.655) \\ &= 243,375 \text{ kJ/kmol}\end{aligned}$$

Substituting,

$$\ln K_p = -(243,375 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol}\cdot\text{K})(2000 \text{ K})] = -14.636$$

or

$$K_p = 4.4 \times 10^{-7} \quad (\text{Table A-28: } \ln K_p = -14.622)$$

16-87 A mixture of H_2 and Ar is heated until 10% of H_2 is dissociated. The final temperature of mixture is to be determined.

Assumptions 1 The constituents of the mixture are ideal gases. 2 Ar in the mixture remains an inert gas.

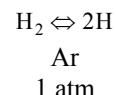

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $H_2 \rightleftharpoons 2H$ (thus $\nu_{H_2} = 1$ and $\nu_H = 2$)

Actual: $H_2 + Ar \longrightarrow \underbrace{0.2H}_{\text{prod}} + \underbrace{0.90H_2}_{\text{react.}} + \underbrace{Ar}_{\text{inert}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_H^{\nu_H}}{N_{H_2}^{\nu_{H_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_H - \nu_{H_2}} = \frac{0.2^2}{0.9} \left(\frac{1}{0.9 + 0.2 + 1} \right)^{2-1} = 0.02116$$

and

$$\ln K_p = -3.855$$

From Table A-28, the temperature corresponding to this K_p value is $T = 2974 \text{ K}$.

16-88 The equilibrium constant for the reaction $\text{CH}_4 + 2\text{O}_2 \rightleftharpoons \text{CO}_2 + 2\text{H}_2\text{O}$ at 100 kPa and 2000 K is to be determined.

Assumptions 1 The constituents of the mixture are ideal gases.

Analysis This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction (Table A-28),

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

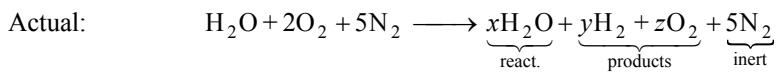

$$\ln K_P = \mathbf{12.356}$$

$$\begin{aligned} \text{CH}_4 + 2\text{O}_2 &\rightleftharpoons \\ \text{CO}_2 + 2\text{H}_2\text{O} & \\ 3000 \text{ K} & \\ 690 \text{ kPa} & \end{aligned}$$

16-89 A mixture of H₂O, O₂, and N₂ is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of H₂O, O₂, N₂ and H₂. 2 The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

H balance: $2 = 2x + 2y \rightarrow y = 1 - x$

O balance: $5 = x + 2z \rightarrow z = 2.5 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z + 5 = 8.5 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{H_2}^{v_{H_2}} N_{O_2}^{v_{O_2}}}{N_{H_2O}^{v_{H_2O}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{H_2} - v_{O_2} - v_{H_2O})} = \frac{y}{x} z^{0.5} \left(\frac{P}{N_{\text{total}}} \right)^{1+0.5-1}$$

From Table A-28, lnK_P = -6.768 at 2200 K. Thus K_P = 0.00115. Substituting,

$$0.00115 = \frac{(1-x)(1.5-0.5x)^{0.5}}{x} \left(\frac{5}{8.5-0.5x} \right)^{0.5}$$

Solving for x,

$$x = 0.9981$$

Then,

$$y = 1 - x = 0.0019$$

$$z = 2.5 - 0.5x = 2.00095$$

Therefore, the equilibrium composition of the mixture at 2200 K and 5 atm is

The equilibrium constant for the reaction H₂O ⇌ OH + $\frac{1}{2}$ H₂ is lnK_P = -7.148, which is very close to the K_P value of the reaction considered. Therefore, it is not realistic to assume that no OH will be present in equilibrium mixture.

1 H ₂ O
2 O ₂
5 N ₂
2200 K
5 atm

16-90 Methane gas is burned with stoichiometric amount of air during a combustion process. The equilibrium composition and the exit temperature are to be determined.

Assumptions 1 The product gases consist of CO₂, H₂O, CO, N₂, and O₂. 2 The constituents of the mixture are ideal gases. 3 This is an adiabatic and steady-flow combustion process.

Analysis (a) The combustion equation of CH₄ with stoichiometric amount of O₂ can be written as

After combustion, there will be no CH₄ present in the combustion chamber, and H₂O will act like an inert gas. The equilibrium equation among CO₂, CO, and O₂ can be expressed as

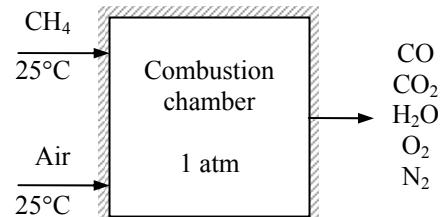

and $K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$

where $N_{\text{total}} = x + (1-x) + (1.5 - 0.5x) + 2 + 7.52 = 12.02 - 0.5x$

Substituting,

$$K_p = \frac{(1-x)(0.5 - 0.5x)^{0.5}}{x} \left(\frac{1}{12.02 - 0.5x} \right)^{1.5-1}$$

The value of K_p depends on temperature of the products, which is yet to be determined. A second relation to determine K_p and x is obtained from the steady-flow energy balance expressed as

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow 0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since the combustion is adiabatic and the reactants enter the combustion chamber at 25°C. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	$\bar{h}_f^\circ, \text{ kJ/kmol}$	$\bar{h}_{298\text{ K}}, \text{ kJ/kmol}$
CH ₄ (g)	-74,850	--
N ₂	0	8669
O ₂	0	8682
H ₂ O(g)	-241,820	9904
CO	-110,530	8669
CO ₂	-393,520	9364

Substituting,

$$0 = x(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1-x)(-110,530 + \bar{h}_{\text{CO}} - 8669) \\ + 2(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.5 - 0.5x)(0 + \bar{h}_{\text{O}_2} - 8682) \\ + 7.52(0 + \bar{h}_{\text{N}_2} - 8669) - 1(-74,850 + h_{298} - h_{298}) - 0 - 0$$

which yields

$$x\bar{h}_{\text{CO}_2} + (1-x)\bar{h}_{\text{CO}} + 2\bar{h}_{\text{H}_2\text{O}} + (0.5 - 0.5x)\bar{h}_{\text{O}_2} + 7.52\bar{h}_{\text{N}_2} - 279,344x = 617,329$$

Now we have two equations with two unknowns, T_p and x . The solution is obtained by trial and error by assuming a temperature T_p , calculating the equilibrium composition from the first equation, and then checking to see if the second equation is satisfied. A first guess is obtained by assuming there is no CO in the products, i.e., $x = 1$. It yields $T_p = 2328\text{ K}$. The adiabatic combustion temperature with incomplete combustion will be less.

$$\text{Take } T_p = 2300\text{ K} \longrightarrow \ln K_p = -4.49 \longrightarrow x = 0.870 \longrightarrow \text{RHS} = 641,093$$

$$\text{Take } T_p = 2250\text{ K} \longrightarrow \ln K_p = -4.805 \longrightarrow x = 0.893 \longrightarrow \text{RHS} = 612,755$$

By interpolation, $T_p = 2258\text{ K}$ and $x = 0.889$

Thus the composition of the equilibrium mixture is

16-91 Problem 16-90 is reconsidered. The effect of excess air on the equilibrium composition and the exit temperature by varying the percent excess air from 0 to 200 percent is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

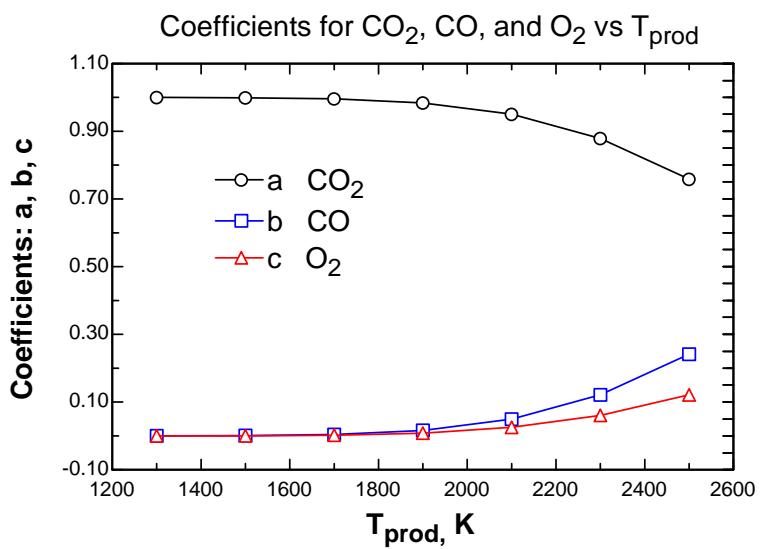

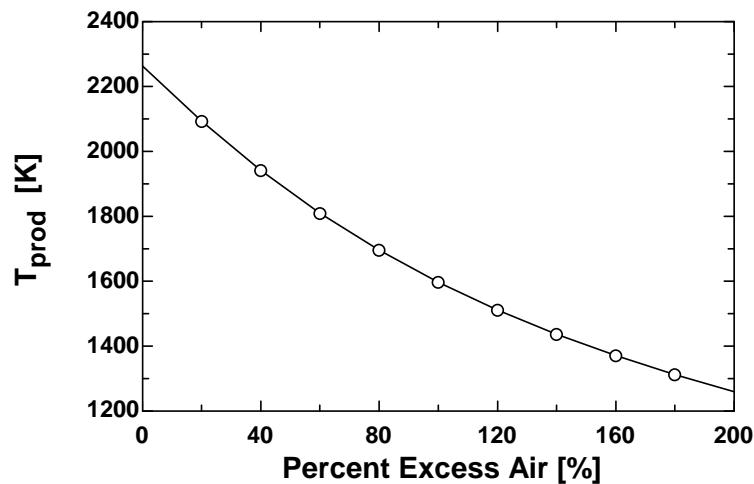

"Often, for nonlinear problems such as this one, good gusses are required to start the solution. First, run the program with zero percent excess air to determine the net heat transfer as a function of T_prod. Just press F3 or click on the Solve Table icon. From Plot Window 1, where Q_net is plotted vs T_prod, determine the value of T_prod for Q_net=0 by holding down the Shift key and move the cross hairs by moving the mouse. Q_net is approximately zero at T_prod = 2269 K. From Plot Window 2 at T_prod = 2269 K, a, b, and c are approximately 0.89, 0.10, and 0.056, respectively." "For EES to calculate a, b, c, and T_prod directly for the adiabatic case, remove the '{ }' in the last line of this window to set Q_net = 0.0. Then from the Options menu select Variable Info and set the Guess Values of a, b, c, and T_prod to the guess values selected from the Plot Windows. Then press F2 or click on the Calculator icon."

16-92 The equilibrium partial pressure of the carbon dioxide for the reaction $\text{CH}_4 + 2\text{O}_2 \rightleftharpoons \text{CO}_2 + 2\text{H}_2\text{O}$ at 700 kPa and 3000 K is to be determined.

Assumptions 1 The equilibrium composition consists of CH_4 , O_2 , CO_2 , and H_2O . **2** The constituents of the mixture are ideal gases.

Analysis This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction,

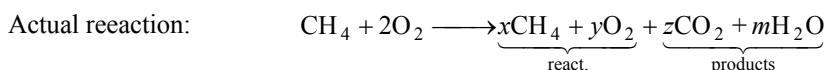

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

$$\ln K_P = 12.356$$

$$\text{C balance: } 1 = x + z \longrightarrow z = 1 - x$$

$$\text{H balance: } 4 = 4x + 2m \longrightarrow m = 2 - 2x$$

$$\text{O balance: } 4 = 2y + 2z + m \longrightarrow y = 2x$$

$$\text{Total number of moles: } N_{\text{total}} = x + y + z + m = 3$$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}} N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}}{N_{\text{CH}_4}^{\nu_{\text{CH}_4}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CO}_2} + \nu_{\text{H}_2\text{O}} - \nu_{\text{CH}_4} - \nu_{\text{O}_2}}$$

Substituting,

$$e^{12.356} = \frac{(1-x)(2-2x)^2}{x(2x)^2} \left(\frac{700/101.325}{3} \right)^{1+2-1-2}$$

Solving for x ,

$$x = 0.01601$$

Then,

$$y = 2x = 0.03202$$

$$z = 1 - x = 0.98399$$

$$m = 2 - 2x = 1.96798$$

Therefore, the equilibrium composition of the mixture at 3000 K and 700 kPa is

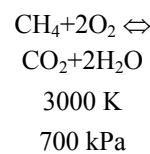

The mole fraction of carbon dioxide is

$$\gamma_{\text{CO}_2} = \frac{0.98399}{3} = 0.3280$$

and the partial pressure of the carbon dioxide in the product mixture is

$$P_{\text{CO}_2} = \gamma_{\text{CO}_2} P = (0.3280)(700 \text{kPa}) = \mathbf{230 \text{ kPa}}$$

16-93 Methane is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

Properties The molar mass and gas constant of methane are 16.043 kg/kmol and 0.5182 kJ/kg·K (Table A-1).

Assumptions 1 The equilibrium composition consists of O₂ and O. **2** The constituents of the mixture are ideal gases.

Analysis (a) An energy balance for the process gives

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} = N(\bar{u}_2 - \bar{u}_1)$$

$$= N[\bar{h}_2 - \bar{h}_1 - R_u(T_2 - T_1)]$$

Using the empirical coefficients of Table A-2c,

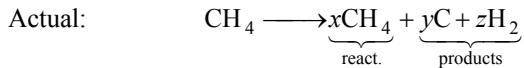

$$\begin{aligned}\bar{h}_2 - \bar{h}_1 &= \int_1^2 c_p dT = a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 19.89(1000 - 298) + \frac{0.05024}{2}(1000^2 - 298^2) + \frac{1.269 \times 10^{-5}}{3}(1000^3 - 298^3) \\ &\quad + \frac{-11.01 \times 10^{-9}}{4}(1000^4 - 298^4) \\ &= 38,239 \text{ kJ/kmol}\end{aligned}$$

CH₄
 1000 K
 1 atm

Substituting,

$$Q_{\text{in}} = (10 \text{ kmol})[38,239 \text{ kJ/kmol} - (8.314 \text{ kJ/kmol} \cdot \text{K})(1000 - 298)\text{K}] = \mathbf{324,000 \text{ kJ}}$$

(b) The stoichiometric and actual reactions in this case are

C balance: 1 = x + y → y = 1 - x

H balance: 4 = 4x + 2z → z = 2 - 2x

Total number of moles: N_{total} = x + y + z = 3 - 2x

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_C^{\nu_C} N_{\text{H}_2}^{\nu_{\text{H}_2}}}{N_{\text{CH}_4}^{\nu_{\text{CH}_4}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_C + \nu_{\text{H}_2} - \nu_{\text{CH}_4}}$$

From the problem statement, at 1000 K, ln K_p = -2.328. Then,

$$K_p = e^{-2.328} = 0.09749$$

Substituting,

$$0.09749 = \frac{(1-x)(2-2x)^2}{x} \left(\frac{1}{3-2x} \right)^{1+2-1}$$

Solving for x,

$$x = 0.6414$$

Then,

$$y = 1 - x = 0.3586$$

$$z = 2 - 2x = 0.7172$$

Therefore, the equilibrium composition of the mixture at 1000 K and 1 atm is

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_{\text{total}}} = \frac{0.6414}{0.6414 + 0.3586 + 0.7172} = \frac{0.6414}{1.7172} = 0.3735$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_{\text{total}}} = \frac{0.3586}{1.7172} = 0.2088$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{0.7172}{1.7172} = 0.4177$$

The heat transfer can be determined from

$$\begin{aligned} Q_{\text{in}} &= N(y_{\text{CH}_4}c_{v,\text{CH}_4}T_2 + y_{\text{H}_2}c_{v,\text{H}_2}T_2 + y_{\text{C}}c_{v,\text{C}}T_2) - Nc_{v,\text{CH}_4}T_1 \\ &= (10)[(0.3735)(63.3)(1000) + (0.4177)(21.7)(1000) + (0.2088)(0.711)(1000)] - (10)(27.8)(298) \\ &= \mathbf{245,700 \text{ kJ}} \end{aligned}$$

16-94 Solid carbon is burned with a stoichiometric amount of air. The number of moles of CO₂ formed per mole of carbon is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and N₂. 2 The constituents of the mixture are ideal gases.

Analysis Inspection of Table A-28 reveals that the dissociation equilibrium constants of CO₂, O₂, and N₂ are quite small and therefore may be neglected. (We learned from another source that the equilibrium constant for CO is also small). The combustion is then complete and the reaction is described by

The number of moles of CO₂ in the products is then

$$\frac{N_{CO_2}}{N_C} = 1$$

Carbon + Air
25°C

16-95 Solid carbon is burned with a stoichiometric amount of air. The amount of heat released per kilogram of carbon is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and N₂. 2 The constituents of the mixture are ideal gases.

Analysis Inspection of Table A-28 reveals that the dissociation equilibrium constants of CO₂, O₂, and N₂ are quite small and therefore may be neglected. (We learned from another source that the equilibrium constant for CO is also small). The combustion is then complete and the reaction is described by

Carbon + Air
25°C

The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f°	\bar{h}_{298K}	\bar{h}_{1240K}
	kJ/kmol	kJ/kmol	kJ/kmol
N ₂	0	8669	38,129
CO ₂	-393,520	9364	56,108

Substituting,

$$\begin{aligned} -Q_{out} &= (1)(-393,520 + 56,108 - 9364) + (3.76)(0 + 38,129 - 8669) \\ &= -236,000 \text{ kJ/kmol C} \end{aligned}$$

or $Q_{out} = \frac{236,000 \text{ kJ/kmol}}{12 \text{ kg/kmol}} = \mathbf{19,670 \text{ kJ/kg C}}$

16-96 Methane gas is burned with 30 percent excess air. The equilibrium composition of the products of combustion and the amount of heat released by this combustion are to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, H₂O, O₂, NO, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis Inspection of the equilibrium constants of the possible reactions indicate that only the formation of NO need to be considered in addition to other complete combustion products. Then, the stoichiometric and actual reactions in this case are Stoichiometric: N₂ + O₂ ⇌ 2NO (thus ν_{N2} = 1, ν_{O2} = 1, and ν_{NO} = 2)

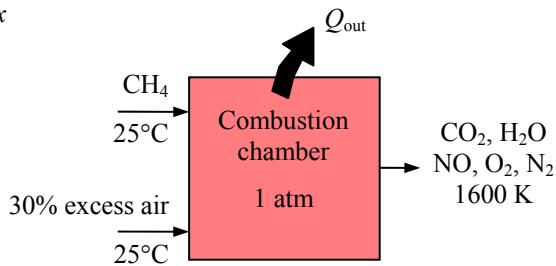

N balance: 2 × 9.776 = x + 2z → z = 9.776 - 0.5x

O balance: 5.2 = 2 + 2 + x + 2y → y = 0.6 - 0.5x

Total number of moles: N_{total} = 1 + 2 + x + y + z = 13.38

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 1600 K, ln K_p = -5.294. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 5.294) = 2.522 \times 10^{-5}$$

Substituting,

$$2.522 \times 10^{-5} = \frac{x^2}{(0.6 - 0.5x)(9.766 - 0.5x)} \left(\frac{1}{13.38} \right)^{2-1-1}$$

Solving for x,

$$x = 0.0121$$

Then,

$$y = 0.6 - 0.5x = 0.594$$

$$z = 9.776 - 0.5x = 9.77$$

Therefore, the equilibrium composition of the products mixture at 1600 K and 1 atm is

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $\bar{h} = \bar{h}(T)$. From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298\text{K}}$	$\bar{h}_{1600\text{K}}$
	kJ/kmol	kJ/kmol	kJ/kmol
CH ₄	-74,850	---	---
O ₂	0	8682	52,961
N ₂	0	8669	50,571
H ₂ O	-241,820	9904	62,748
CO ₂	-393,520	9364	76,944

Neglecting the effect of NO in the energy balance and substituting,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= (1)(-393,520 + 76,944 - 9364) + (2)(-241,820 + 62,748 - 9904) + 0.594(52,961 - 8682) \\ &\quad + (9.77)(50,571 - 8669) - (-74,850) \\ &= -193,500 \text{ kJ/kmol CH}_4 \end{aligned}$$

or $\dot{Q}_{\text{out}} = 193,500 \text{ kJ/kmol CH}_4$

16-97E Gaseous octane gas is burned with 40% excess air. The equilibrium composition of the products of combustion is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, H₂O, O₂, NO, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: N₂ + O₂ ⇌ 2NO (thus ν_{N2} = 1, ν_{O2} = 1, and ν_{NO} = 2)

Actual: C₈H₁₈ + 1.4 × 12.5(O₂ + 3.76N₂) → 8CO₂ + 9H₂O + xNO + yO₂ + zN₂

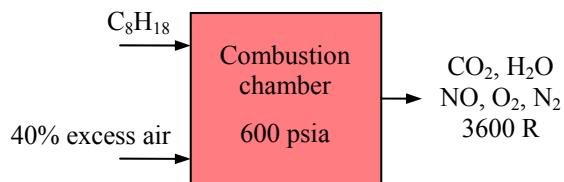

$$\text{N balance: } 131.6 = x + 2z \rightarrow z = 65.8 - 0.5x$$

$$\text{O balance: } 35 = 16 + 9 + x + 2y \rightarrow y = 5 - 0.5x$$

$$\text{Total number of moles: } N_{\text{total}} = 8 + 9 + x + y + z = 87.8$$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 2000 K (3600 R), ln K_p = -3.931. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 3.931) = 3.851 \times 10^{-4}$$

Substituting,

$$3.851 \times 10^{-4} = \frac{x^2}{(5 - 0.5x)(65.8 - 0.5x)} \left(\frac{600 / 14.7}{87.8} \right)^{2-1-1}$$

Solving for x,

$$x = 0.3492$$

Then,

$$y = 5 - 0.5x = 4.825$$

$$z = 65.8 - 0.5x = 65.63$$

Therefore, the equilibrium composition of the products mixture at 2000 K and 4 MPa is

16-98 Propane gas is burned with 20% excess air. The equilibrium composition of the products of combustion on a mass basis and the amount of heat released by this combustion are to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, H₂O, O₂, NO, and N₂. 2 The constituents of the mixture are ideal gases.

Analysis (a) The stoichiometric and actual reactions in this case are

N balance: $45.12 = x + 2z \longrightarrow z = 22.56 - 0.5x$

O balance: $12 = 6 + 4 + x + 2y \longrightarrow y = 1 - 0.5x$

Total number of moles: $N_{\text{total}} = 3 + 4 + x + y + z = 30.56$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{v_{\text{NO}}}}{N_{\text{N}_2}^{v_{\text{N}_2}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{NO}} - v_{\text{N}_2} - v_{\text{O}_2})}$$

From Table A-28, at 2000 K, $\ln K_p = -3.931$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 3.931) = 3.851 \times 10^{-4}$$

Substituting,

$$3.851 \times 10^{-4} = \frac{x^2}{(1 - 0.5x)(22.56 - 0.5x)} \left(\frac{1}{30.56} \right)^{2-1-1}$$

Solving for x ,

$$x = 0.09097$$

Then,

$$y = 1 - 0.5x = 0.9545$$

$$z = 22.56 - 0.5x = 22.51$$

Therefore, the equilibrium composition of the products mixture at 2000 K and 1 atm is

The mass of each product and the total mass of the products is

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (3 \text{ kmol})(44 \text{ kg/kmol}) = 132 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (4 \text{ kmol})(18 \text{ kg/kmol}) = 72 \text{ kg}$$

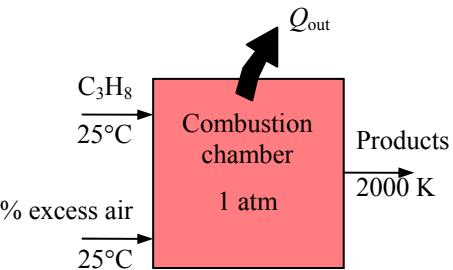

$$m_{\text{NO}} = N_{\text{NO}} M_{\text{NO}} = (0.09097 \text{ kmol})(30 \text{ kg/kmol}) = 2.73 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (0.9545 \text{ kmol})(32 \text{ kg/kmol}) = 30.54 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (22.51 \text{ kmol})(28 \text{ kg/kmol}) = 630.28 \text{ kg}$$

$$m_{\text{total}} = 132 + 72 + 2.73 + 30.54 + 630.28 = 867.55 \text{ kg}$$

The mass fractions of the products are

$$mf_{CO_2} = \frac{m_{CO_2}}{m_{total}} = \frac{132 \text{ kg}}{867.55 \text{ kg}} = \mathbf{0.1522}$$

$$mf_{H_2O} = \frac{m_{H_2O}}{m_{total}} = \frac{72 \text{ kg}}{867.55 \text{ kg}} = \mathbf{0.0830}$$

$$mf_{NO} = \frac{m_{NO}}{m_{total}} = \frac{2.73 \text{ kg}}{867.55 \text{ kg}} = \mathbf{0.0031}$$

$$mf_{O_2} = \frac{m_{O_2}}{m_{total}} = \frac{30.54 \text{ kg}}{867.55 \text{ kg}} = \mathbf{0.0352}$$

$$mf_{N_2} = \frac{m_{N_2}}{m_{total}} = \frac{630.28 \text{ kg}}{867.55 \text{ kg}} = \mathbf{0.7265}$$

(b) The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-\dot{Q}_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	\bar{h}_{298K} kJ/kmol	\bar{h}_{1600K} kJ/kmol
C ₃ H ₈	-103,850	---	---
O ₂	0	8682	67,881
N ₂	0	8669	64,810
H ₂ O	-241,820	9904	82,593
CO ₂	-393,520	9364	100,804

Neglecting the effect of NO in the energy balance and substituting,

$$\begin{aligned} -\dot{Q}_{out} &= (3)(-393,520 + 100,804 - 9364) + (4)(-241,820 + 82,593 - 9904) + 0.9545(67,881 - 8682) \\ &\quad + (22.51)(64,810 - 8669) - (-103,850) \\ &= -158,675 \text{ kJ/kmol C}_3\text{H}_8 \end{aligned}$$

or $\dot{Q}_{out} = \frac{158,675 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = \mathbf{3606 \text{ kJ/kg C}_3\text{H}_8}$

16-99 Propane gas is burned with stoichiometric air in an adiabatic manner. The temperature of the products and the equilibrium composition of the products are to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, H₂O, O₂, NO, and N₂. 2 The constituents of the mixture are ideal gases.

Analysis (a) The stoichiometric and actual reactions in this case are

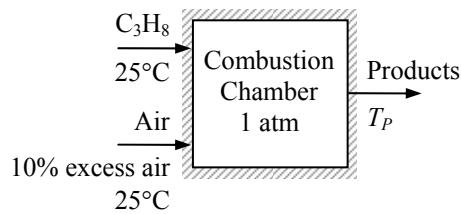

N balance: $41.36 = x + 2z \longrightarrow z = 20.68 - 0.5x$

O balance: $11 = 6 + 4 + x + 2y \longrightarrow y = 0.5 - 0.5x$

Total number of moles: $N_{\text{total}} = 3 + 4 + x + y + z = 21.18$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{v_{\text{NO}}}}{N_{\text{N}_2}^{v_{\text{N}_2}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{NO}} - v_{\text{N}_2} - v_{\text{O}_2})}$$

We assume that the products will be at 2000 K. Then from Table A-28, at 2000 K, $\ln K_p = -3.931$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 3.931) = 3.851 \times 10^{-4}$$

Substituting,

$$3.851 \times 10^{-4} = \frac{x^2}{(0.5 - 0.5x)(20.68 - 0.5x)} \left(\frac{1}{21.18} \right)^{2-1-1}$$

Solving for x,

$$x = 0.0611$$

Then,

$$y = 0.5 - 0.5x = 0.4695$$

$$z = 20.68 - 0.5x = 20.65$$

Therefore, the equilibrium composition of the products mixture at 2000 K and 1 atm is

(b) From the tables,

Substance	$\bar{h}_f^\circ, \text{kJ/kmol}$	$\bar{h}_{298\text{K}}, \text{kJ/kmol}$
C ₃ H ₈ (g)	-103,850	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO ₂	-393,520	9364

Thus,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.0611)(39,460 + \bar{h}_{\text{NO}} - 9188) + (0.4695)(0 + \bar{h}_{\text{O}_2} - 8682) + (20.65)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850) + 0 + 0$$

It yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 0.0611\bar{h}_{\text{OH}} + 0.4695\bar{h}_{\text{O}_2} + 20.65\bar{h}_{\text{N}_2} = 2,292,940 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,292,940/(3+4+0.0611+0.4695+20.65) = 81,366 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2450 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 2450 K, but somewhat under it because of the higher specific heat of H₂O.

At 2200 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 0.0611\bar{h}_{\text{OH}} + 0.4695\bar{h}_{\text{O}_2} + 20.65\bar{h}_{\text{N}_2} &= 3(112,939) + 4(92,940) + 0.0611(69,932) \\ &+ 0.4695(75,484) + 20.65(64,810) = 2,088,620 \text{ kJ} \text{ (Lower than 2,292,940)} \end{aligned}$$

At 2400 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 0.0611\bar{h}_{\text{OH}} + 0.4695\bar{h}_{\text{O}_2} + 20.65\bar{h}_{\text{N}_2} &= 3(125,152) + 4(103,508) + 0.0611(77,015) \\ &+ 0.4695(83,174) + 20.65(79,320) = 2,471,200 \text{ kJ} \text{ (Higher than 2,292,940)} \end{aligned}$$

By interpolation of the two results,

$$T_P = \mathbf{2307 \text{ K} = 2034^\circ\text{C}}$$

16-100 A mixture of H₂O and O₂ is heated to a high temperature. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of H₂O, OH, O₂, and H₂. 2 The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for hydrogen and oxygen yield

$$\text{H balance: } 4 = 2x + 2y + w \quad (1)$$

$$\text{O balance: } 8 = x + 2z + w \quad (2)$$

H ₂ O, OH, H ₂ , O ₂
3600 K
8 atm

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_P relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3600 K are determined from Table A-28 to be

$$\ln K_{P1} = -1.392 \longrightarrow K_{P1} = 0.24858$$

$$\ln K_{P2} = -1.088 \longrightarrow K_{P2} = 0.33689$$

The K_P relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

$$K_{P2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

where

$$N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.24858 = \frac{(y)(z)^{1/2}}{x} \left(\frac{8}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.33689 = \frac{(w)(y)^{1/2}}{x} \left(\frac{8}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 1.371 \quad y = 0.1646 \quad z = 2.85 \quad w = 0.928$$

Therefore, the equilibrium composition becomes

16-101 A mixture of CO₂ and O₂ is heated to a high temperature. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and O. 2 The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for carbon and oxygen yield

$$\text{C balance: } 3 = x + y \quad (1)$$

$$\text{O balance: } 12 = 2x + y + 2z + w \quad (2)$$

CO ₂ , CO, O ₂ , O
2600 K
1.5 atm

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_P relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 2600 K are determined from Table A-28 to be

$$\ln K_{P1} = -2.801 \longrightarrow K_{P1} = 0.06075$$

$$\ln K_{P2} = -7.521 \longrightarrow K_{P2} = 0.0005416$$

The K_P relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

$$K_{P2} = \frac{N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{O}} - \nu_{\text{O}_2}}$$

where

$$N_{\text{total}} = N_{\text{CO}_2} + N_{\text{O}_2} + N_{\text{CO}} + N_{\text{O}} = x + y + z + w$$

Substituting,

$$0.06075 = \frac{(y)(z)^{1/2}}{x} \left(\frac{1.5}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.0005416 = \frac{w^2}{z} \left(\frac{1.5}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 2.803 \quad y = 0.197 \quad z = 3.057 \quad w = 0.08233$$

Thus the equilibrium composition is

16-102 Problem 16-101 is reconsidered. The effect of pressure on the equilibrium composition by varying pressure from 1 atm to 10 atm is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

16-103 The \bar{h}_R at a specified temperature is to be determined using enthalpy and K_p data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The complete combustion equation of H₂ can be expressed as

The \bar{h}_R of the combustion process of H₂ at 2400 K is the amount of energy released as one kmol of H₂ is burned in a steady-flow combustion chamber at a temperature of 2400 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the H₂O, H₂, and O₂ to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2400\text{ K}}$ kJ/kmol
H ₂ O	-241,820	9904	103,508
H ₂	0	8468	75,383
O ₂	0	8682	83,174

Substituting,

$$\begin{aligned}\bar{h}_R &= 1(-241,820 + 103,508 - 9904) \\ &\quad - 1(0 + 75,383 - 8468) \\ &\quad - 0.5(0 + 83,174 - 8682) \\ &= \mathbf{-252,377 \text{ kJ / kmol}}\end{aligned}$$

(b) The \bar{h}_R value at 2400 K can be estimated by using K_p values at 2200 K and 2600 K (the closest two temperatures to 2400 K for which K_p data are available) from Table A-28,

$$\begin{aligned}\ln \frac{K_{P2}}{K_{P1}} &\approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \text{ or } \ln K_{P2} - \ln K_{P1} \approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ 4.648 - 6.768 &\approx \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2200 \text{ K}} - \frac{1}{2600 \text{ K}} \right) \\ \bar{h}_R &\approx \mathbf{-252,047 \text{ kJ/kmol}}\end{aligned}$$

16-104 Problem 16-103 is reconsidered. The effect of temperature on the enthalpy of reaction using both methods by varying the temperature from 2000 to 3000 K is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data"

$$\begin{aligned} T_{prod} &= 2400 \text{ [K]} \\ \Delta T_{prod} &= 25 \text{ [K]} \\ R_u &= 8.314 \text{ [kJ/kmol-K]} \\ T_{prod_1} &= T_{prod} - \Delta T_{prod} \\ T_{prod_2} &= T_{prod} + \Delta T_{prod} \end{aligned}$$

"The combustion equation is $1 \text{ H}_2 + 0.5 \text{ O}_2 \Rightarrow 1 \text{ H}_2\text{O}$ "

"The enthalpy of reaction $\bar{h}_{R,R}$ using enthalpy data is:"

$$\begin{aligned} \bar{h}_{R,R,\text{Enthalpy}} &= HP - HR \\ HP &= 1 * \text{Enthalpy}(\text{H}_2\text{O}, T=T_{prod}) \\ HR &= 1 * \text{Enthalpy}(\text{H}_2, T=T_{prod}) + 0.5 * \text{Enthalpy}(\text{O}_2, T=T_{prod}) \end{aligned}$$

"The enthalpy of reaction $\bar{h}_{R,R}$ using enthalpy data is found using the following equilibrium data:" "The following equations provide the specific Gibbs function ($g=h-Ts$) for each component as a function of its temperature at 1 atm pressure, 101.3 kPa"

$$\begin{aligned} g_{\text{H}_2\text{O}_1} &= \text{Enthalpy}(\text{H}_2\text{O}, T=T_{prod_1}) - T_{prod_1} * \text{Entropy}(\text{H}_2\text{O}, T=T_{prod_1}, P=101.3) \\ g_{\text{H}_2_1} &= \text{Enthalpy}(\text{H}_2, T=T_{prod_1}) - T_{prod_1} * \text{Entropy}(\text{H}_2, T=T_{prod_1}, P=101.3) \\ g_{\text{O}_2_1} &= \text{Enthalpy}(\text{O}_2, T=T_{prod_1}) - T_{prod_1} * \text{Entropy}(\text{O}_2, T=T_{prod_1}, P=101.3) \\ g_{\text{H}_2\text{O}_2} &= \text{Enthalpy}(\text{H}_2\text{O}, T=T_{prod_2}) - T_{prod_2} * \text{Entropy}(\text{H}_2\text{O}, T=T_{prod_2}, P=101.3) \\ g_{\text{H}_2_2} &= \text{Enthalpy}(\text{H}_2, T=T_{prod_2}) - T_{prod_2} * \text{Entropy}(\text{H}_2, T=T_{prod_2}, P=101.3) \\ g_{\text{O}_2_2} &= \text{Enthalpy}(\text{O}_2, T=T_{prod_2}) - T_{prod_2} * \text{Entropy}(\text{O}_2, T=T_{prod_2}, P=101.3) \end{aligned}$$

"The standard-state (at 1 atm) Gibbs functions are"

$$\begin{aligned} \Delta G_{\text{prod}} &= 1 * g_{\text{H}_2\text{O}_1} - 0.5 * g_{\text{O}_2_1} - 1 * g_{\text{H}_2_1} \\ \Delta G_{\text{prod}} &= 1 * g_{\text{H}_2\text{O}_2} - 0.5 * g_{\text{O}_2_2} - 1 * g_{\text{H}_2_2} \end{aligned}$$

"The equilibrium constants are given by Eq. 15-14."

$$K_p = \exp(-\Delta G_{\text{prod}} / (R_u * T_{prod})) \text{ "From EES data"}$$

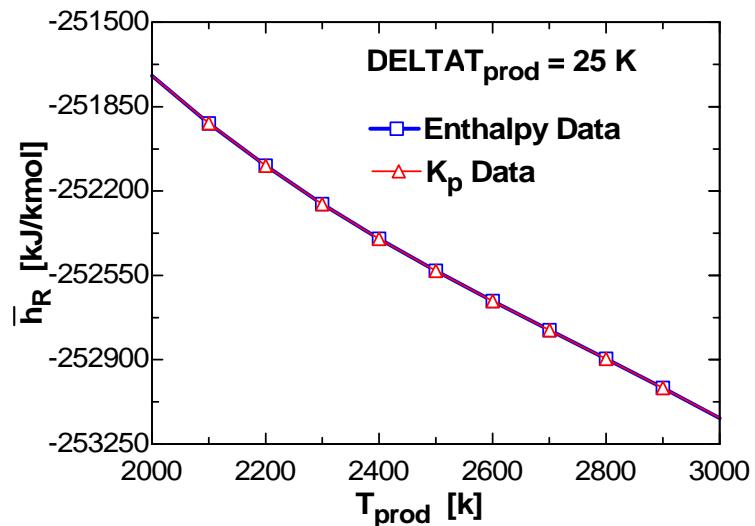

$$K_p = \exp(-\Delta G_{\text{prod}} / (R_u * T_{prod})) \text{ "From EES data"}$$

"the enthalpy of reaction is estimated from the equilibrium constant K_p by using EQ 15-18 as:"

$$\ln(K_p / K_{p,1}) = \bar{h}_{R,R,\text{Enthalpy}} / (R_u * (1/T_{prod_1} - 1/T_{prod_2}))$$

$$\text{PercentError} = \text{ABS}((\bar{h}_{R,R,\text{Enthalpy}} - \bar{h}_{R,R,K_p}) / \bar{h}_{R,R,\text{Enthalpy}}) * \text{Convert}(, \%)$$

0.00005154	2900	-253017	-253017
0.0000405	3000	-253142	-253142

16-105 The K_P value of the dissociation process $O_2 \rightleftharpoons 2O$ at a specified temperature is to be determined using the \bar{h}_R data and K_P value at a specified temperature.

Assumptions Both the reactants and products are ideal gases.

Analysis The \bar{h}_R and K_P data are related to each other by

$$\ln \frac{K_{P2}}{K_{P1}} \approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \approx \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$$

The \bar{h}_R of the specified reaction at 2800 K is the amount of energy released as one kmol of O_2 dissociates in a steady-flow combustion chamber at a temperature of 2800 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O_2 and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298\text{ K}}$	$\bar{h}_{2800\text{ K}}$
	kJ/kmol	kJ/kmol	kJ/kmol
O	249,190	6852	59,241
O_2	0	8682	98,826

Substituting,

$$\begin{aligned}\bar{h}_R &= 2(249,190 + 59,241 - 6852) - 1(0 + 98,826 - 8682) \\ &= 513,014 \text{ kJ / kmol}\end{aligned}$$

The K_P value at 3000 K can be estimated from the equation above by using this \bar{h}_R value and the K_P value at 2600 K which is $\ln K_{P1} = -7.521$,

$$\ln K_{P2} - (-7.521) = \frac{513,014 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2600 \text{ K}} - \frac{1}{3000 \text{ K}} \right)$$

$$\ln K_{P2} = -4.357 \quad (\text{Table A - 28 : } \ln K_{P2} = -4.357)$$

or

$$K_{P2} = \mathbf{0.0128}$$

16-106 A mixture of CO and O₂ contained in a tank is ignited. The final pressure in the tank and the amount of heat transfer are to be determined.

Assumptions 1 The equilibrium composition consists of CO₂ and O₂. **2** Both the reactants and the products are ideal gases.

Analysis The combustion equation can be written as

The heat transfer can be determined from

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

CO₂, CO, O₂
25°C
3 atm

Both the reactants and the products are assumed to be ideal gases, and thus all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$-\dot{Q}_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{800\text{ K}} - \bar{h}_{298\text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298\text{ K}}$	$\bar{h}_{800\text{ K}}$
	kJ/kmol	kJ/kmol	kJ/kmol
CO	-110,530	8669	23,844
O ₂	0	8682	24,523
CO ₂	-393,520	9364	32,179

Substituting,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= 1(-393,520 + 32,179 - 9364 - 8.314 \times 800) \\ &\quad + 2.5(0 + 24,523 - 8682 - 8.314 \times 800) \\ &\quad - 3(0 - 8.314 \times 298) \\ &\quad - 1(-110,530 - 8.314 \times 298) \\ &= \mathbf{-233,940 \text{ kJ/kmol CO}} \end{aligned}$$

or

$$\dot{Q}_{\text{out}} = \mathbf{233,940 \text{ kJ/kmol CO}}$$

The final pressure in the tank is determined from

$$\frac{P_1 V}{P_2 V} = \frac{N_1 R_u T_1}{N_2 R_u T_2} \longrightarrow P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{3.5}{4} \times \frac{800\text{ K}}{298\text{ K}} (3 \text{ atm}) = \mathbf{7.05 \text{ atm}}$$

The equilibrium constant for the reaction $\text{CO} + \frac{1}{2}\text{O}_2 \rightleftharpoons \text{CO}_2$ at 800 K is $\ln K_p = 37.2$ (by interpolation), which is much greater than 7.05. Therefore, it is not realistic to assume that no CO will be present in equilibrium mixture.

16-107 A 2-L bottle is filled with carbonated drink that is fully charged (saturated) with CO₂ gas. The volume that the CO₂ gas would occupy if it is released and stored in a container at room conditions is to be determined.

Assumptions 1 The liquid drink can be treated as water. 2 Both the CO₂ gas and the water vapor are ideal gases. 3 The CO₂ gas is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 17°C is 1.938 kPa (Table A-4). Henry's constant for CO₂ dissolved in water at 17°C (290 K) is $H = 1280 \text{ bar}$ (Table 16-2). Molar masses of CO₂ and water are 44.01 and 18.015 kg/kmol, respectively (Table A-1). The gas constant of CO₂ is 0.1889 kPa·m³/kg·K. Also, 1 bar = 100 kPa.

Analysis In the charging station, the CO₂ gas and water vapor mixture above the liquid will form a saturated mixture. Noting that the saturation pressure of water at 17°C is 1.938 kPa, the partial pressure of the CO₂ gas is

$$P_{\text{CO}_2, \text{gas side}} = P - P_{\text{vapor}} = P - P_{\text{sat}@17^\circ\text{C}} = 600 - 1.938 = 598.06 \text{ kPa} = 5.9806 \text{ bar}$$

From Henry's law, the mole fraction of CO₂ in the liquid drink is determined to be

$$\gamma_{\text{CO}_2, \text{liquid side}} = \frac{P_{\text{CO}_2, \text{gas side}}}{H} = \frac{5.9806 \text{ bar}}{1280 \text{ bar}} = 0.00467$$

Then the mole fraction of water in the drink becomes

$$\gamma_{\text{water, liquid side}} = 1 - \gamma_{\text{CO}_2, \text{liquid side}} = 1 - 0.00467 = 0.99533$$

The mass and mole fractions of a mixture are related to each other by

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = \gamma_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO₂ mixture) is

$$\begin{aligned} M_m &= \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{CO}_2} M_{\text{CO}_2} \\ &= 0.99533 \times 18.015 + 0.00467 \times 44.01 = 18.14 \text{ kg/kmol} \end{aligned}$$

Then the mass fraction of dissolved CO₂ in liquid drink becomes

$$w_{\text{CO}_2, \text{liquid side}} = \gamma_{\text{CO}_2, \text{liquid side}} (0) \frac{M_{\text{CO}_2}}{M_m} = 0.00467 \frac{44.01}{18.14} = 0.0113$$

Therefore, the mass of dissolved CO₂ in a 2 L ≈ 2 kg drink is

$$m_{\text{CO}_2} = w_{\text{CO}_2} m_m = 0.0113(2 \text{ kg}) = 0.0226 \text{ kg}$$

Then the volume occupied by this CO₂ at the room conditions of 20°C and 100 kPa becomes

$$V = \frac{mRT}{P} = \frac{(0.0226 \text{ kg})(0.1889 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{100 \text{ kPa}} = \mathbf{0.0125 \text{ m}^3 = 12.5 \text{ L}}$$

Discussion Note that the amount of dissolved CO₂ in a 2-L pressurized drink is large enough to fill 6 such bottles at room temperature and pressure. Also, we could simplify the calculations by assuming the molar mass of carbonated drink to be the same as that of water, and take it to be 18 kg/kmol because of the very low mole fraction of CO₂ in the drink.

16-108 Ethyl alcohol C_2H_5OH (gas) is burned in a steady-flow adiabatic combustion chamber with 90 percent excess air. The adiabatic flame temperature of the products is to be determined and the adiabatic flame temperature as a function of the percent excess air is to be plotted.

Analysis The complete combustion reaction in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The oxygen balance gives

$$1 + (1 + Ex)a_{th} \times 2 = 2 \times 2 + 3 \times 1 + (Ex)(a_{th}) \times 2$$

The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

$$\text{Carbon balance: } 2 = a + b$$

$$\text{Hydrogen balance: } 6 = 2d \longrightarrow d = 3$$

$$\text{Oxygen balance: } 1 + (1 + Ex)a_{th} \times 2 = a \times 2 + b + d + e \times 2$$

$$\text{Nitrogen balance: } (1 + Ex)a_{th} \times 3.76 = f$$

Solving the above equations, we find the coefficients to be

$$Ex = 0.9, a_{th} = 3, a = 2, b = 0.00008644, d = 3, e = 2.7, f = 21.43$$

Then, we write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 2 + 0.00008644 + 3 + 2.7 + 21.43 = 29.13$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{CO}\bar{g}_{CO}^*(T_{\text{prod}}) + \nu_{O_2}\bar{g}_{O_2}^*(T_{\text{prod}}) - \nu_{CO_2}\bar{g}_{CO_2}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{CO}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{CO}$$

$$\bar{g}_{O_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{O_2}$$

$$\bar{g}_{CO_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{CO_2}$$

The equilibrium constant is also given by

$$K_p = \frac{be^{0.5}}{a} \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{(0.00008644)(2.7)^{0.5}}{2} \left(\frac{1}{29.13} \right)^{0.5} = 0.00001316$$

A steady flow energy balance gives

$$H_R = H_P$$

where

$$\begin{aligned} H_R &= \bar{h}_f^o_{\text{fuel}@25^\circ\text{C}} + 5.7\bar{h}_{\text{O}_2@25^\circ\text{C}} + 21.43\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= (-235,310 \text{ kJ/kmol}) + 5.7(0) + 21.43(0) = -235,310 \text{ kJ/kmol} \end{aligned}$$

$$H_P = 2\bar{h}_{\text{CO}_2@T_{\text{prod}}} + 0.00008644\bar{h}_{\text{CO}@T_{\text{prod}}} + 3\bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} + 2.7\bar{h}_{\text{O}_2@T_{\text{prod}}} + 21.43\bar{h}_{\text{N}_2@T_{\text{prod}}}$$

Solving the energy balance equation using EES, we obtain the adiabatic flame temperature to be

$$T_{\text{prod}} = 1569 \text{ K}$$

16-109 The percent theoretical air required for the combustion of octane such that the volume fraction of CO in the products is less than 0.1% and the heat transfer are to be determined. Also, the percent theoretical air required for 0.1% CO in the products as a function of product pressure is to be plotted.

Analysis The complete combustion reaction equation for excess air is

The oxygen balance is

$$P_{\text{th}} a_{\text{th}} \times 2 = 8 \times 2 + 9 \times 1 + (P_{\text{th}} - 1)a_{\text{th}} \times 2$$

The reaction equation for excess air and products in equilibrium is

The coefficients are to be determined from the mass balances

$$\text{Carbon balance: } 8 = a + b$$

$$\text{Hydrogen balance: } 18 = 2d \longrightarrow d = 9$$

$$\text{Oxygen balance: } P_{\text{th}} a_{\text{th}} \times 2 = a \times 2 + b + d + e \times 2$$

$$\text{Nitrogen balance: } P_{\text{th}} a_{\text{th}} \times 3.76 = f$$

Volume fraction of CO must be less than 0.1%. That is,

$$\gamma_{\text{CO}} = \frac{b}{N_{\text{tot}}} = \frac{b}{a+b+d+e+f} = 0.001$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data:

$$\bar{g}_{\text{CO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{CO}} = (-53,826) - (2000)(258.48) = -570,781 \text{ kJ/kmol}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{O}_2} = (59,193) - (2000)(268.53) = -477,876 \text{ kJ/kmol}$$

$$\bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{CO}_2} = (-302,128) - (2000)(309.00) = -920,121 \text{ kJ/kmol}$$

The enthalpies at 2000 K and entropies at 2000 K and 101.3 kPa are obtained from EES. Substituting,

$$\begin{aligned} \Delta G^*(T_{\text{prod}}) &= \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) \\ &= 1(-570,781) + 0.5(-477,876) - (-920,121) = 110,402 \text{ kJ/kmol} \end{aligned}$$

$$K_p = \exp\left(\frac{-\Delta G^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right) = \exp\left(\frac{-110,402}{(8.314)(2000)}\right) = 0.001308$$

The equilibrium constant is also given by

$$K_p = \frac{be^{0.5}}{a} \left(\frac{P}{N_{\text{tot}}}\right)^{1+0.5-1} = \frac{be^{0.5}}{a} \left(\frac{P_{\text{prod}} / 101.3}{a+b+d+e+f}\right)^{1+0.5-1}$$

The steady flow energy balance gives

$$H_R = Q_{\text{out}} + H_P$$

where

$$\begin{aligned}
 H_R &= 1\bar{h}_{\text{C8H18}@298\text{ K}} + P_{\text{th}} a_{\text{th}} \bar{h}_{\text{O}_2 @ 298\text{ K}} + (P_{\text{th}} a_{\text{th}} \times 3.76) \bar{h}_{\text{N}_2 @ 298\text{ K}} \\
 &= (-208,459) + P_{\text{th}} a_{\text{th}} (0) + (P_{\text{th}} a_{\text{th}} \times 3.76)(0) = -208,459 \text{ kJ/kmol} \\
 H_P &= a\bar{h}_{\text{CO}_2 @ 2000\text{ K}} + b\bar{h}_{\text{CO} @ 2000\text{ K}} + d\bar{h}_{\text{H}_2\text{O} @ 2000\text{ K}} + e\bar{h}_{\text{O}_2 @ 2000\text{ K}} + f\bar{h}_{\text{N}_2 @ 2000\text{ K}} \\
 &= a(-302,128) + b(-53,826) + d(-169,171) + e(59,193) + f(56,115)
 \end{aligned}$$

The enthalpies are obtained from EES. Solving all the equations simultaneously using EES, we obtain

$$\begin{aligned}
 P_{\text{th}} &= 1.024, \quad a_{\text{th}} = 12.5, \quad a = 7.935, \quad b = 0.06544, \quad d = 9, \quad e = 0.3289, \quad f = 48.11 \\
 \text{PercentTh} &= P_{\text{th}} \times 100 = 1.024 \times 100 = \mathbf{102.4\%} \\
 Q_{\text{out}} &= \mathbf{995,500 \text{ kJ/kmol C}_8\text{H}_{18}}
 \end{aligned}$$

16-110 It is to be shown that when the three phases of a pure substance are in equilibrium, the specific Gibbs function of each phase is the same.

Analysis The total Gibbs function of the three phase mixture of a pure substance can be expressed as

$$G = m_s g_s + m_\ell g_\ell + m_g g_g$$

where the subscripts s , ℓ , and g indicate solid, liquid and gaseous phases. Differentiating by holding the temperature and pressure (thus the Gibbs functions, g) constant yields

$$dG = g_s dm_s + g_\ell dm_\ell + g_g dm_g$$

From conservation of mass,

$$dm_s + dm_\ell + dm_g = 0 \quad \longrightarrow \quad dm_s = -dm_\ell - dm_g$$

Substituting,

$$dG = -g_s(dm_\ell + dm_g) + g_\ell dm_\ell + g_g dm_g$$

Rearranging,

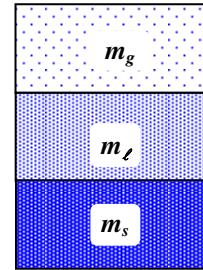

$$dG = (g_\ell - g_s)dm_\ell + (g_g - g_s)dm_g$$

For equilibrium, $dG = 0$. Also dm_ℓ and dm_g can be varied independently. Thus each term on the right hand side must be zero to satisfy the equilibrium criteria. It yields

$$g_\ell = g_s \quad \text{and} \quad g_g = g_s$$

Combining these two conditions gives the desired result,

$$g_\ell = g_s = g_g$$

16-111 It is to be shown that when the two phases of a two-component system are in equilibrium, the specific Gibbs function of each phase of each component is the same.

Analysis The total Gibbs function of the two phase mixture can be expressed as

$$G = (m_{\ell 1}g_{\ell 1} + m_{g 1}g_{g 1}) + (m_{\ell 2}g_{\ell 2} + m_{g 2}g_{g 2})$$

where the subscripts ℓ and g indicate liquid and gaseous phases. Differentiating by holding the temperature and pressure (thus the Gibbs functions) constant yields

$$dG = g_{\ell 1}dm_{\ell 1} + g_{g 1}dm_{g 1} + g_{\ell 2}dm_{\ell 2} + g_{g 2}dm_{g 2}$$

From conservation of mass,

$$dm_{g 1} = -dm_{\ell 1} \quad \text{and} \quad dm_{g 2} = -dm_{\ell 2}$$

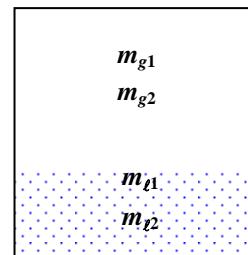

Substituting,

$$dG = (g_{\ell 1} - g_{g 1})dm_{\ell 1} + (g_{\ell 2} - g_{g 2})dm_{\ell 2}$$

For equilibrium, $dG = 0$. Also $dm_{\ell 1}$ and $dm_{\ell 2}$ can be varied independently. Thus each term on the right hand side must be zero to satisfy the equilibrium criteria. Then we have

$$g_{\ell 1} = g_{g 1} \quad \text{and} \quad g_{\ell 2} = g_{g 2}$$

which is the desired result.

16-112 Using Henry's law, it is to be shown that the dissolved gases in a liquid can be driven off by heating the liquid.

Analysis Henry's law is expressed as

$$y_{i, \text{liquid side}}(0) = \frac{P_{i, \text{gas side}}(0)}{H}$$

Henry's constant H increases with temperature, and thus the fraction of gas i in the liquid $y_{i, \text{liquid side}}$ decreases. Therefore, heating a liquid will drive off the dissolved gases in a liquid.

Fundamentals of Engineering (FE) Exam Problems

16-113 If the equilibrium constant for the reaction $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$ is K , the equilibrium constant for the reaction $2\text{H}_2\text{O} \rightarrow 2\text{H}_2 + \text{O}_2$ at the same temperature is

Answer (e) $1/K^2$

16-114 If the equilibrium constant for the reaction $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$ is K , the equilibrium constant for the reaction $\text{CO}_2 + 3\text{N}_2 \rightarrow \text{CO} + \frac{1}{2}\text{O}_2 + 3\text{N}_2$, at the same temperature is

Answer (a) $1/K$

16-115 The equilibrium constant for the reaction $H_2 + \frac{1}{2}O_2 \rightarrow H_2O$ at 1 atm and 1500°C is given to be K . Of the reactions given below, all at 1500°C, the reaction that has a different equilibrium constant is

- (a) $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$ at 5 atm,
 - (b) $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$ at 1 atm,
 - (c) $\text{H}_2 + \text{O}_2 \rightarrow \text{H}_2\text{O} + \frac{1}{2}\text{O}_2$ at 2 atm,
 - (d) $\text{H}_2 + \frac{1}{2}\text{O}_2 + 3\text{N}_2 \rightarrow \text{H}_2\text{O} + 3\text{N}_2$ at 5 atm,
 - (e) $\text{H}_2 + \frac{1}{2}\text{O}_2 + 3\text{N}_2 \rightarrow \text{H}_2\text{O} + 3\text{N}_2$ at 1 atm,

Answer (b) $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$ at 1 atm,

16-116 Of the reactions given below, the reaction whose equilibrium composition at a specified temperature is not affected by pressure is

- (a) $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$
 (b) $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$
 (c) $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$
 (d) $\text{N}_2 \rightarrow 2\text{N}$
 (e) all of the above.

Answer (c) $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$

16-117 Of the reactions given below, the reaction whose number of moles of products increases by the addition of inert gases into the reaction chamber at constant pressure and temperature is

- (a) $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$
- (b) $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$
- (c) $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$
- (d) $\text{N}_2 \rightarrow 2\text{N}$
- (e) none of the above.

Answer (d) $\text{N}_2 \rightarrow 2\text{N}$

16-118 Moist air is heated to a very high temperature. If the equilibrium composition consists of H_2O , O_2 , N_2 , OH , H_2 , and NO , the number of equilibrium constant relations needed to determine the equilibrium composition of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

Answer (c) 3

16-119 Propane C_3H_8 is burned with air, and the combustion products consist of CO_2 , CO , H_2O , O_2 , N_2 , OH , H_2 , and NO . The number of equilibrium constant relations needed to determine the equilibrium composition of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

Answer (d) 4

16-120 Consider a gas mixture that consists of three components. The number of independent variables that need to be specified to fix the state of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

Answer (d) 4

16-121 The value of Henry's constant for CO₂ gas dissolved in water at 290 K is 12.8 MPa. Consider water exposed to air at 100 kPa that contains 3 percent CO₂ by volume. Under phase equilibrium conditions, the mole fraction of CO₂ gas dissolved in water at 290 K is

- (a) 2.3×10^{-4} (b) 3.0×10^{-4} (c) 0.80×10^{-4} (d) 2.2×10^{-4} (e) 5.6×10^{-4}

Answer (a) 2.3×10^{-4}

Stagnation Properties

17-1C No, there is not significant error, because the velocities encountered in air-conditioning applications are very low, and thus the static and the stagnation temperatures are practically identical.

Discussion If the air stream were supersonic, however, the error would indeed be significant.

17-2C Stagnation enthalpy combines the ordinary enthalpy and the kinetic energy of a fluid, and offers convenience when analyzing high-speed flows. It differs from the ordinary enthalpy by the kinetic energy term.

Discussion Most of the time, we mean specific enthalpy, i.e., enthalpy per unit mass, when we use the term enthalpy.

17-3C Dynamic temperature is the temperature rise of a fluid during a stagnation process.

Discussion When a gas decelerates from high speed to zero speed at a stagnation point, the temperature of the gas rises.

17-4C The temperature of the air rises as it approaches the nose because of the stagnation process.

Discussion In the frame of reference moving with the aircraft, the air decelerates from high speed to zero at the nose (stagnation point), and this causes the air temperature to rise.

17-5 The inlet stagnation temperature and pressure and the exit stagnation pressure of air flowing through a compressor are specified. The power input to the compressor is to be determined.

Assumptions 1 The compressor is isentropic. 2 Air is an ideal gas.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The exit stagnation temperature of air T_{02} is determined from

$$T_{02} = T_{01} \left(\frac{P_{02}}{P_{01}} \right)^{(k-1)/k} = (300.2 \text{ K}) \left(\frac{900}{100} \right)^{(1.4-1)/1.4} = 562.4 \text{ K}$$

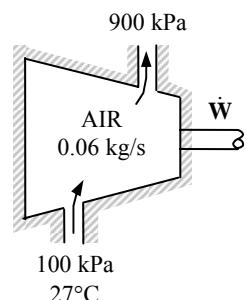

From the energy balance on the compressor,

$$\dot{W}_{\text{in}} = \dot{m}(h_{20} - h_{01})$$

or,

$$\dot{W}_{\text{in}} = \dot{m}c_p(T_{02} - T_{01}) = (0.06 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(562.4 - 300.2) \text{ K} = 15.8 \text{ kW}$$

Discussion Note that the stagnation properties can be used conveniently in the energy equation.

17-6 Air at 320 K is flowing in a duct. The temperature that a stationary probe inserted into the duct will read is to be determined for different air velocities.

Assumptions The stagnation process is isentropic.

Properties The specific heat of air at room temperature is $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

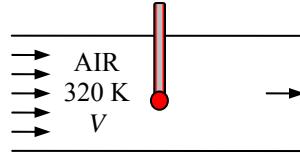

Analysis The air which strikes the probe will be brought to a complete stop, and thus it will undergo a stagnation process. The thermometer will sense the temperature of this stagnated air, which is the stagnation temperature, T_0 . It is determined from $T_0 = T + \frac{V^2}{2c_p}$. The results for each case are calculated below:

$$(a) \quad T_0 = 320 \text{ K} + \frac{(1 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{320.0 \text{ K}}$$

$$(b) \quad T_0 = 320 \text{ K} + \frac{(10 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{320.1 \text{ K}}$$

$$(c) \quad T_0 = 320 \text{ K} + \frac{(100 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{325.0 \text{ K}}$$

$$(d) \quad T_0 = 320 \text{ K} + \frac{(1000 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{817.5 \text{ K}}$$

Discussion Note that the stagnation temperature is nearly identical to the thermodynamic temperature at low velocities, but the difference between the two is significant at high velocities.

17-7 The states of different substances and their velocities are specified. The stagnation temperature and stagnation pressures are to be determined.

Assumptions 1 The stagnation process is isentropic. **2** Helium and nitrogen are ideal gases.

Analysis (a) Helium can be treated as an ideal gas with $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$. Then the stagnation temperature and pressure of helium are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 50^\circ\text{C} + \frac{(240 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{55.5^\circ\text{C}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.25 \text{ MPa}) \left(\frac{328.7 \text{ K}}{323.2 \text{ K}} \right)^{1.667/(1.667-1)} = \mathbf{0.261 \text{ MPa}}$$

(b) Nitrogen can be treated as an ideal gas with $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.400$. Then the stagnation temperature and pressure of nitrogen are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 50^\circ\text{C} + \frac{(300 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{93.3^\circ\text{C}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.15 \text{ MPa}) \left(\frac{366.5 \text{ K}}{323.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{0.233 \text{ MPa}}$$

(c) Steam can be treated as an ideal gas with $c_p = 1.865 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.329$. Then the stagnation temperature and pressure of steam are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 350^\circ\text{C} + \frac{(480 \text{ m/s})^2}{2 \times 1.865 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{411.8^\circ\text{C} = 685 \text{ K}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.1 \text{ MPa}) \left(\frac{685 \text{ K}}{623.2 \text{ K}} \right)^{1.329/(1.329-1)} = \mathbf{0.147 \text{ MPa}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-8 The state of air and its velocity are specified. The stagnation temperature and stagnation pressure of air are to be determined.

Assumptions 1 The stagnation process is isentropic. **2** Air is an ideal gas.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The stagnation temperature of air is determined from

$$T_0 = T + \frac{V^2}{2c_p} = 238 \text{ K} + \frac{(470 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 347.9 \text{ K} \approx \mathbf{348 \text{ K}}$$

Other stagnation properties at the specified state are determined by considering an isentropic process between the specified state and the stagnation state,

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (36 \text{ kPa}) \left(\frac{347.9 \text{ K}}{238 \text{ K}} \right)^{1.4/(1.4-1)} = 135.9 \text{ kPa} \approx \mathbf{136 \text{ kPa}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-9E Steam flows through a device. The stagnation temperature and pressure of steam and its velocity are specified. The static pressure and temperature of the steam are to be determined.

Assumptions 1 The stagnation process is isentropic. **2** Steam is an ideal gas.

Properties Steam can be treated as an ideal gas with $c_p = 0.4455 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.329$.

Analysis The static temperature and pressure of steam are determined from

$$T = T_0 - \frac{V^2}{2c_p} = 700^\circ\text{F} - \frac{(900 \text{ ft/s})^2}{2 \times 0.4455 \text{ Btu/lbm}\cdot\text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = \mathbf{663.7^\circ\text{F}}$$

$$P = P_0 \left(\frac{T}{T_0} \right)^{k/(k-1)} = (120 \text{ psia}) \left(\frac{1123.7 \text{ R}}{1160 \text{ R}} \right)^{1.329/(1.329-1)} = \mathbf{105.5 \text{ psia}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-10 Air flows through a device. The stagnation temperature and pressure of air and its velocity are specified. The static pressure and temperature of air are to be determined.

Assumptions 1 The stagnation process is isentropic. **2** Air is an ideal gas.

Properties The properties of air at an anticipated average temperature of 600 K are $c_p = 1.051 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.376$.

Analysis The static temperature and pressure of air are determined from

$$T = T_0 - \frac{V^2}{2c_p} = 673.2 - \frac{(570 \text{ m/s})^2}{2 \times 1.051 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{518.6 \text{ K}}$$

and

$$P_2 = P_{02} \left(\frac{T_2}{T_{02}} \right)^{k/(k-1)} = (0.6 \text{ MPa}) \left(\frac{518.6 \text{ K}}{673.2 \text{ K}} \right)^{1.376/(1.376-1)} = \mathbf{0.23 \text{ MPa}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-11 The inlet stagnation temperature and pressure and the exit stagnation pressure of products of combustion flowing through a gas turbine are specified. The power output of the turbine is to be determined.

Assumptions 1 The expansion process is isentropic. **2** Products of combustion are ideal gases.

Properties The properties of products of combustion are $c_p = 1.157 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.33$.

Analysis The exit stagnation temperature T_{02} is determined to be

$$T_{02} = T_{01} \left(\frac{P_{02}}{P_{01}} \right)^{(k-1)/k} = (1023.2 \text{ K}) \left(\frac{0.1}{1} \right)^{(1.33-1)/1.33} = 577.9 \text{ K}$$

Also,

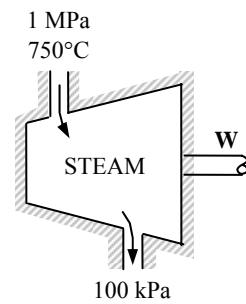

$$\begin{aligned} c_p &= kc_v = k(c_p - R) \longrightarrow c_p = \frac{kR}{k-1} \\ &= \frac{1.33(0.287 \text{ kJ/kg}\cdot\text{K})}{1.33-1} \\ &= 1.157 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

From the energy balance on the turbine,

$$-w_{\text{out}} = (h_{20} - h_{01})$$

$$\text{or, } w_{\text{out}} = c_p (T_{01} - T_{02}) = (1.157 \text{ kJ/kg}\cdot\text{K})(1023.2 - 577.9) \text{ K} = 515.2 \text{ kJ/kg} \approx \mathbf{515 \text{ kJ/kg}}$$

Discussion Note that the stagnation properties can be used conveniently in the energy equation.

Speed of Sound and Mach Number

17-12C *Sound is an infinitesimally small pressure wave. It is generated by a small disturbance in a medium. It travels by wave propagation. Sound waves cannot travel in a vacuum.*

Discussion Electromagnetic waves, like light and radio waves, can travel in a vacuum, but sound cannot.

17-13C *Yes, the propagation of sound waves is nearly isentropic.* Because the amplitude of an ordinary sound wave is very small, and it does not cause any significant change in temperature and pressure.

Discussion No process is truly isentropic, but the increase of entropy due to sound propagation is negligibly small.

17-14C *The sonic speed in a medium depends on the properties of the medium, and it changes as the properties of the medium change.*

Discussion The most common example is the change in speed of sound due to temperature change.

17-15C Sound travels faster in **warm (higher temperature) air** since $c = \sqrt{kRT}$.

Discussion On the microscopic scale, we can imagine the air molecules moving around at higher speed in warmer air, leading to higher propagation of disturbances.

17-16C *Sound travels fastest in helium*, since $c = \sqrt{kRT}$ and helium has the highest kR value. It is about 0.40 for air, 0.35 for argon, and 3.46 for helium.

Discussion We are assuming, of course, that these gases behave as ideal gases – a good approximation at room temperature.

17-17C Air at specified conditions will behave like an ideal gas, and *the speed of sound in an ideal gas depends on temperature only*. Therefore, **the speed of sound is the same in both mediums**.

Discussion If the temperature were different, however, the speed of sound would be different.

17-18C In general, **no**, because the Mach number also depends on the speed of sound in gas, which depends on the temperature of the gas. **The Mach number remains constant only if the temperature and the velocity are constant.**

Discussion It turns out that the speed of sound is not a strong function of pressure. In fact, it is not a function of pressure at all for an ideal gas.

17-19 The Mach number of an aircraft and the speed of sound in air are to be determined at two specified temperatures.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis From the definitions of the speed of sound and the Mach number,

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{347 \text{ m/s}}$$

$$\text{and } \text{Ma} = \frac{V}{c} = \frac{240 \text{ m/s}}{347 \text{ m/s}} = \mathbf{0.692}$$

(b) At 1000 K,

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(1000 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{634 \text{ m/s}}$$

$$\text{and } \text{Ma} = \frac{V}{c} = \frac{240 \text{ m/s}}{634 \text{ m/s}} = \mathbf{0.379}$$

Discussion Note that a constant Mach number does not necessarily indicate constant speed. The Mach number of a rocket, for example, will be increasing even when it ascends at constant speed. Also, the specific heat ratio k changes with temperature, and the accuracy of the result at 1000 K can be improved by using the k value at that temperature (it would give $k = 1.386$, $c = 619 \text{ m/s}$, and $\text{Ma} = 0.388$).

17-20 Carbon dioxide flows through a nozzle. The inlet temperature and velocity and the exit temperature of CO₂ are specified. The Mach number is to be determined at the inlet and exit of the nozzle.

Assumptions 1 CO₂ is an ideal gas with constant specific heats at room temperature. 2 This is a steady-flow process.

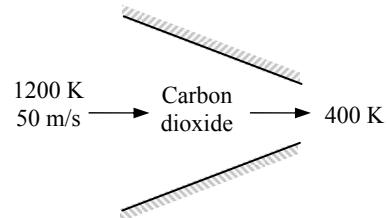

Properties The gas constant of carbon dioxide is $R = 0.1889 \text{ kJ/kg}\cdot\text{K}$. Its constant pressure specific heat and specific heat ratio at room temperature are $c_p = 0.8439 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.288$.

Analysis (a) At the inlet

$$c_1 = \sqrt{k_1 RT_1} = \sqrt{(1.288)(0.1889 \text{ kJ/kg}\cdot\text{K})(1200 \text{ K}) \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 540.3 \text{ m/s}$$

Thus,

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{50 \text{ m/s}}{540.3 \text{ m/s}} = \mathbf{0.0925}$$

(b) At the exit,

$$c_2 = \sqrt{k_2 RT_2} = \sqrt{(1.288)(0.1889 \text{ kJ/kg}\cdot\text{K})(400 \text{ K}) \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 312.0 \text{ m/s}$$

The nozzle exit velocity is determined from the steady-flow energy balance relation,

$$0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \rightarrow 0 = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$0 = (0.8439 \text{ kJ/kg}\cdot\text{K})(400 - 1200 \text{ K}) + \frac{V_2^2 - (50 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2 / \text{s}^2} \right) \rightarrow V_2 = 1163 \text{ m/s}$$

Thus,

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1163 \text{ m/s}}{312 \text{ m/s}} = \mathbf{3.73}$$

Discussion The specific heats and their ratio k change with temperature, and the accuracy of the results can be improved by accounting for this variation. Using EES (or another property database):

At 1200 K: $c_p = 1.278 \text{ kJ/kg}\cdot\text{K}$, $k = 1.173 \rightarrow c_1 = 516 \text{ m/s}$, $V_1 = 50 \text{ m/s}$, $\text{Ma}_1 = 0.0969$

At 400 K: $c_p = 0.9383 \text{ kJ/kg}\cdot\text{K}$, $k = 1.252 \rightarrow c_2 = 308 \text{ m/s}$, $V_2 = 1356 \text{ m/s}$, $\text{Ma}_2 = 4.41$

Therefore, the constant specific heat assumption results in an error of **4.5%** at the inlet and **15.5%** at the exit in the Mach number, which are significant.

17-21 Nitrogen flows through a heat exchanger. The inlet temperature, pressure, and velocity and the exit pressure and velocity are specified. The Mach number is to be determined at the inlet and exit of the heat exchanger.

Assumptions 1 N₂ is an ideal gas. 2 This is a steady-flow process. 3 The potential energy change is negligible.

Properties The gas constant of N₂ is $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$. Its constant pressure specific heat and specific heat ratio at room temperature are $c_p = 1.040 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis

$$c_1 = \sqrt{k_1 RT_1} = \sqrt{(1.400)(0.2968 \text{ kJ/kg}\cdot\text{K})(283 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 342.9 \text{ m/s}$$

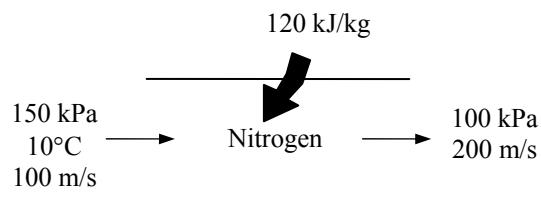

Thus,

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{100 \text{ m/s}}{342.9 \text{ m/s}} = \mathbf{0.292}$$

From the energy balance on the heat exchanger,

$$q_{\text{in}} = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$120 \text{ kJ/kg} = (1.040 \text{ kJ/kg}\cdot\text{C})(T_2 - 10^\circ\text{C}) + \frac{(200 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

It yields

$$T_2 = 111^\circ\text{C} = 384 \text{ K}$$

$$c_2 = \sqrt{k_2 RT_2} = \sqrt{(1.4)(0.2968 \text{ kJ/kg}\cdot\text{K})(384 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 399 \text{ m/s}$$

Thus,

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{200 \text{ m/s}}{399 \text{ m/s}} = \mathbf{0.501}$$

Discussion The specific heats and their ratio k change with temperature, and the accuracy of the results can be improved by accounting for this variation. Using EES (or another property database):

$$\text{At } 10^\circ\text{C} : c_p = 1.038 \text{ kJ/kg}\cdot\text{K}, k = 1.400 \rightarrow c_1 = 343 \text{ m/s}, V_1 = 100 \text{ m/s}, \text{Ma}_1 = 0.292$$

$$\text{At } 111^\circ\text{C} c_p = 1.041 \text{ kJ/kg}\cdot\text{K}, k = 1.399 \rightarrow c_2 = 399 \text{ m/s}, V_2 = 200 \text{ m/s}, \text{Ma}_2 = 0.501$$

Therefore, the constant specific heat assumption results in an error of **4.5%** at the inlet and **15.5%** at the exit in the Mach number, which are almost identical to the values obtained assuming constant specific heats.

17-22 The speed of sound in refrigerant-134a at a specified state is to be determined.

Assumptions R-134a is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of R-134a is $R = 0.08149 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.108$.

Analysis From the ideal-gas speed of sound relation,

$$c = \sqrt{kRT} = \sqrt{(1.108)(0.08149 \text{ kJ/kg}\cdot\text{K})(60+273 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{173 \text{ m/s}}$$

Discussion Note that the speed of sound is independent of pressure for ideal gases.

17-23 The Mach number of a passenger plane for specified limiting operating conditions is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis From the speed of sound relation

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(-60 + 273 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 293 \text{ m/s}$$

Thus, the Mach number corresponding to the maximum cruising speed of the plane is

$$\text{Ma} = \frac{V_{\max}}{c} = \frac{(945 / 3.6) \text{ m/s}}{293 \text{ m/s}} = \mathbf{0.897}$$

Discussion Note that this is a subsonic flight since $\text{Ma} < 1$. Also, using a k value at -60°C would give practically the same result.

17-24E Steam flows through a device at a specified state and velocity. The Mach number of steam is to be determined assuming ideal gas behavior.

Assumptions Steam is an ideal gas with constant specific heats.

Properties The gas constant of steam is $R = 0.1102 \text{ Btu/lbm}\cdot\text{R}$. Its specific heat ratio is given to be $k = 1.3$.

Analysis From the ideal-gas speed of sound relation,

$$c = \sqrt{kRT} = \sqrt{(1.3)(0.1102 \text{ Btu/lbm}\cdot\text{R})(1160 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 2040 \text{ ft/s}$$

Thus,

$$\text{Ma} = \frac{V}{c} = \frac{900 \text{ ft/s}}{2040 \text{ ft/s}} = \mathbf{0.441}$$

Discussion Using property data from steam tables and not assuming ideal gas behavior, it can be shown that the Mach number in steam at the specified state is 0.446, which is sufficiently close to the ideal-gas value of 0.441. Therefore, the ideal gas approximation is a reasonable one in this case.

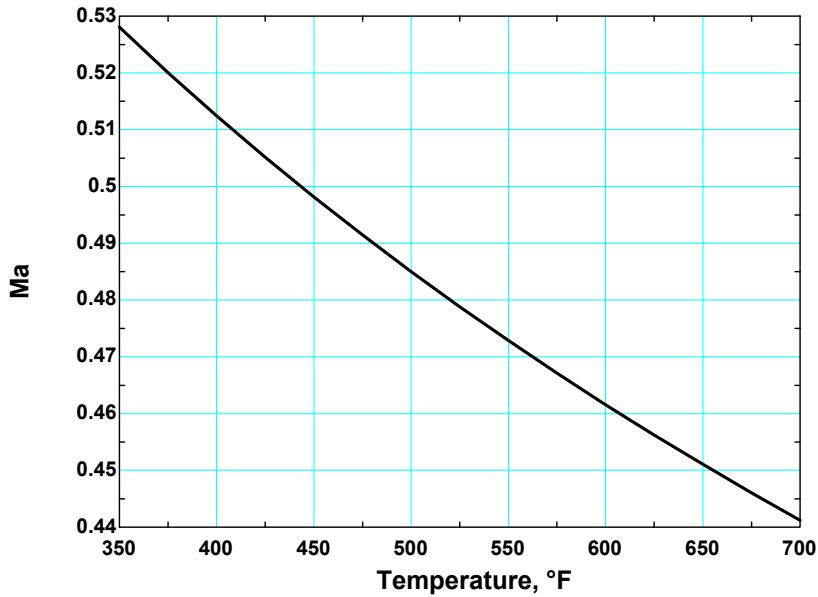

17-25E Problem 17-24E is reconsidered. The variation of Mach number with temperature as the temperature changes between 350° and 700°F is to be investigated, and the results are to be plotted.

Analysis The EES *Equations* window is printed below, along with the tabulated and plotted results.

```
T=Temperature+460
R=0.1102
V=900
k=1.3
c=SQRT(k*R*T*25037)
Ma=V/c
```

Temperature, <i>T</i> , °F	Mach number Ma
350	0.528
375	0.520
400	0.512
425	0.505
450	0.498
475	0.491
500	0.485
525	0.479
550	0.473
575	0.467
600	0.462
625	0.456
650	0.451
675	0.446
700	0.441

Discussion Note that for a specified flow speed, the Mach number decreases with increasing temperature, as expected.

17-26 The expression for the speed of sound for an ideal gas is to be obtained using the isentropic process equation and the definition of the speed of sound.

Analysis The isentropic relation $Pv^k = A$ where A is a constant can also be expressed as

$$P = A \left(\frac{1}{v} \right)^k = A \rho^k$$

Substituting it into the relation for the speed of sound,

$$c^2 = \left(\frac{\partial P}{\partial \rho} \right)_s = \left(\frac{\partial (A \rho^k)}{\partial \rho} \right)_s = k A \rho^{k-1} = k (A \rho^k) / \rho = k (P / \rho) = k R T$$

since for an ideal gas $P = \rho R T$ or $R T = P / \rho$. Therefore, $c = \sqrt{k R T}$, which is the desired relation.

Discussion Notice that pressure has dropped out; the speed of sound in an ideal gas is *not* a function of pressure.

17-27 The inlet state and the exit pressure of air are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$. The specific heat ratio k varies with temperature, but in our case this change is very small and can be disregarded.

Analysis The final temperature of air is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (333.2 \text{ K}) \left(\frac{0.4 \text{ MPa}}{1.5 \text{ MPa}} \right)^{(1.4-1)/1.4} = 228.4 \text{ K}$$

Treating k as a constant, the ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{333.2}}{\sqrt{228.4}} = \mathbf{1.21}$$

Discussion Note that the speed of sound is proportional to the square root of thermodynamic temperature.

17-28 The inlet state and the exit pressure of helium are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

Assumptions Helium is an ideal gas with constant specific heats at room temperature.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$.

Analysis The final temperature of helium is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (333.2 \text{ K}) \left(\frac{0.4}{1.5} \right)^{(1.667-1)/1.667} = 196.3 \text{ K}$$

The ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{333.2}}{\sqrt{196.3}} = \mathbf{1.30}$$

Discussion Note that the speed of sound is proportional to the square root of thermodynamic temperature.

17-29E The inlet state and the exit pressure of air are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$. The specific heat ratio k varies with temperature, but in our case this change is very small and can be disregarded.

Analysis The final temperature of air is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (659.7 \text{ R}) \left(\frac{60}{170} \right)^{(1.4-1)/1.4} = 489.9 \text{ R}$$

Treating k as a constant, the ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{659.7}}{\sqrt{489.9}} = \mathbf{1.16}$$

Discussion Note that the speed of sound is proportional to the square root of thermodynamic temperature.

One Dimensional Isentropic Flow

17-30C (a) The **velocity increases**. (b), (c), (d) The **temperature, pressure, and density of the fluid decrease**.

Discussion The velocity increase is opposite to what happens in supersonic flow.

17-31C (a) The **velocity decreases**. (b), (c), (d) The **temperature, pressure, and density of the fluid increase**.

Discussion The velocity decrease is opposite to what happens in supersonic flow.

17-32C (a) The **exit velocity remains constant at sonic speed**, (b) the **mass flow rate through the nozzle decreases because of the reduced flow area**.

Discussion Without a diverging portion of the nozzle, a converging nozzle is limited to sonic velocity at the exit.

17-33C (a) The **velocity decreases**. (b), (c), (d) The **temperature, pressure, and density of the fluid increase**.

Discussion The velocity decrease is opposite to what happens in subsonic flow.

17-34C (a) The **velocity increases**. (b), (c), (d) The **temperature, pressure, and density of the fluid decrease**.

Discussion The velocity increase is opposite to what happens in subsonic flow.

17-35C The pressures at the two throats are identical.

Discussion Since the gas has the same stagnation conditions, it also has the same sonic conditions at the throat.

17-36C No, it is not possible.

Discussion The only way to do it is to have first a converging nozzle, and then a diverging nozzle.

17-37 The Mach number of scramjet and the air temperature are given. The speed of the engine is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis The temperature is $-20 + 273.15 = 253.15 \text{ K}$. The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(253.15 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 318.93 \text{ m/s}$$

and

$$V = cMa = (318.93 \text{ m/s})(7) \left(\frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right) = 8037 \text{ km/h} \approx \mathbf{8040 \text{ km/h}}$$

Discussion Note that extremely high speed can be achieved with scramjet engines. We cannot justify more than three significant digits in a problem like this.

17-38E The Mach number of scramjet and the air temperature are given. The speed of the engine is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis The temperature is $0 + 459.67 = 459.67 \text{ R}$. The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(459.67 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1050.95 \text{ ft/s}$$

and

$$V = cMa = (1050.95 \text{ ft/s})(7) \left(\frac{1 \text{ mi/h}}{1.46667 \text{ ft/s}} \right) = 5015.9 \text{ mi/h} \approx \mathbf{5020 \text{ mi/h}}$$

Discussion Note that extremely high speed can be achieved with scramjet engines. We cannot justify more than three significant digits in a problem like this.

17-39 The speed of an airplane and the air temperature are given. It is to be determined if the speed of this airplane is subsonic or supersonic.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis The temperature is $-50 + 273.15 = 223.15 \text{ K}$. The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(223.15 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) \left(\frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right) = 1077.97 \text{ km/h}$$

and

$$\text{Ma} = \frac{V}{c} = \frac{920 \text{ km/h}}{1077.97 \text{ km/h}} = 0.85346 \approx \mathbf{0.853}$$

The speed of the airplane is **subsonic** since the Mach number is less than 1.

Discussion Subsonic airplanes stay sufficiently far from the Mach number of 1 to avoid the instabilities associated with transonic flights.

17-40 The critical temperature, pressure, and density of air and helium are to be determined at specified conditions.

Assumptions Air and Helium are ideal gases with constant specific heats at room temperature.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$. The properties of helium at room temperature are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $k = 1.667$, and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) Before we calculate the critical temperature T^* , pressure P^* , and density ρ^* , we need to determine the stagnation temperature T_0 , pressure P_0 , and density ρ_0 .

$$T_0 = 100^\circ\text{C} + \frac{V^2}{2c_p} = 100 + \frac{(250 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 131.1^\circ\text{C}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{404.3 \text{ K}}{373.2 \text{ K}} \right)^{1.4/(1.4-1)} = 264.7 \text{ kPa}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{264.7 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(404.3 \text{ K})} = 2.281 \text{ kg/m}^3$$

Thus,

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (404.3 \text{ K}) \left(\frac{2}{1.4+1} \right) = \mathbf{337 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (264.7 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{140 \text{ kPa}}$$

$$\rho^* = \rho_0 \left(\frac{2}{k+1} \right)^{1/(k-1)} = (2.281 \text{ kg/m}^3) \left(\frac{2}{1.4+1} \right)^{1/(1.4-1)} = \mathbf{1.45 \text{ kg/m}^3}$$

$$(b) \text{ For helium, } T_0 = T + \frac{V^2}{2c_p} = 40 + \frac{(300 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 48.7^\circ\text{C}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{321.9 \text{ K}}{313.2 \text{ K}} \right)^{1.667/(1.667-1)} = 214.2 \text{ kPa}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{214.2 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(321.9 \text{ K})} = 0.320 \text{ kg/m}^3$$

Thus,

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (321.9 \text{ K}) \left(\frac{2}{1.667+1} \right) = \mathbf{241 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (214.2 \text{ kPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = \mathbf{104.3 \text{ kPa}}$$

$$\rho^* = \rho_0 \left(\frac{2}{k+1} \right)^{1/(k-1)} = (0.320 \text{ kg/m}^3) \left(\frac{2}{1.667+1} \right)^{1/(1.667-1)} = \mathbf{0.208 \text{ kg/m}^3}$$

Discussion These are the temperature, pressure, and density values that will occur at the throat when the flow past the throat is supersonic.

17-41 Quiescent carbon dioxide at a given state is accelerated isentropically to a specified Mach number. The temperature and pressure of the carbon dioxide after acceleration are to be determined.

Assumptions Carbon dioxide is an ideal gas with constant specific heats at room temperature.

Properties The specific heat ratio of the carbon dioxide at room temperature is $k = 1.288$.

Analysis The inlet temperature and pressure in this case is equivalent to the stagnation temperature and pressure since the inlet velocity of the carbon dioxide is said to be negligible. That is, $T_0 = T_i = 400 \text{ K}$ and $P_0 = P_i = 1200 \text{ kPa}$. Then,

$$T = T_0 \left(\frac{2}{2 + (k-1)Ma^2} \right) = (600 \text{ K}) \left(\frac{2}{2 + (1.288-1)(0.6)^2} \right) = 570.43 \text{ K} \approx \mathbf{570 \text{ K}}$$

and

$$P = P_0 \left(\frac{T}{T_0} \right)^{k/(k-1)} = (1200 \text{ kPa}) \left(\frac{570.43 \text{ K}}{600 \text{ K}} \right)^{1.288/(1.288-1)} = 957.23 \text{ K} \approx \mathbf{957 \text{ kPa}}$$

Discussion Note that both the pressure and temperature drop as the gas is accelerated as part of the internal energy of the gas is converted to kinetic energy.

17-42 Air enters a converging-diverging nozzle at specified conditions. The lowest pressure that can be obtained at the throat of the nozzle is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio of air at room temperature is $k = 1.4$.

Analysis The lowest pressure that can be obtained at the throat is the critical pressure P^* , which is determined from

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (800 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{423 \text{ kPa}}$$

Discussion This is the pressure that occurs at the throat when the flow past the throat is supersonic.

17-43 Helium enters a converging-diverging nozzle at specified conditions. The lowest temperature and pressure that can be obtained at the throat of the nozzle are to be determined.

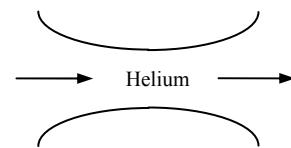

Assumptions 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of helium are $k = 1.667$ and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$.

Analysis The lowest temperature and pressure that can be obtained at the throat are the critical temperature T^* and critical pressure P^* . First we determine the stagnation temperature T_0 and stagnation pressure P_0 ,

$$T_0 = T + \frac{V^2}{2c_p} = 800 \text{ K} + \frac{(100 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{°C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 801 \text{ K}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.7 \text{ MPa}) \left(\frac{801 \text{ K}}{800 \text{ K}} \right)^{1.667/(1.667-1)} = 0.702 \text{ MPa}$$

Thus,

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (801 \text{ K}) \left(\frac{2}{1.667+1} \right) = \mathbf{601 \text{ K}}$$

and

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (0.702 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = \mathbf{0.342 \text{ MPa}}$$

Discussion These are the temperature and pressure that will occur at the throat when the flow past the throat is supersonic.

17-44 Air flows through a duct. The state of the air and its Mach number are specified. The velocity and the stagnation pressure, temperature, and density of the air are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ and $k = 1.4$.

Analysis The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(373.2 \text{ K}) \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 387.2 \text{ m/s}$$

Thus,

$$V = Ma \times c = (0.8)(387.2 \text{ m/s}) = \mathbf{310 \text{ m/s}}$$

Also,

$$\rho = \frac{P}{RT} = \frac{200 \text{ kPa}}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(373.2 \text{ K})} = 1.867 \text{ kg/m}^3$$

Then the stagnation properties are determined from

$$T_0 = T \left(1 + \frac{(k-1)Ma^2}{2} \right) = (373.2 \text{ K}) \left(1 + \frac{(1.4-1)(0.8)^2}{2} \right) = \mathbf{421 \text{ K}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{421.0 \text{ K}}{373.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{305 \text{ kPa}}$$

$$\rho_0 = \rho \left(\frac{T_0}{T} \right)^{1/(k-1)} = (1.867 \text{ kg/m}^3) \left(\frac{421.0 \text{ K}}{373.2 \text{ K}} \right)^{1/(1.4-1)} = \mathbf{2.52 \text{ kg/m}^3}$$

Discussion Note that both the pressure and temperature drop as the gas is accelerated as part of the internal energy of the gas is converted to kinetic energy.

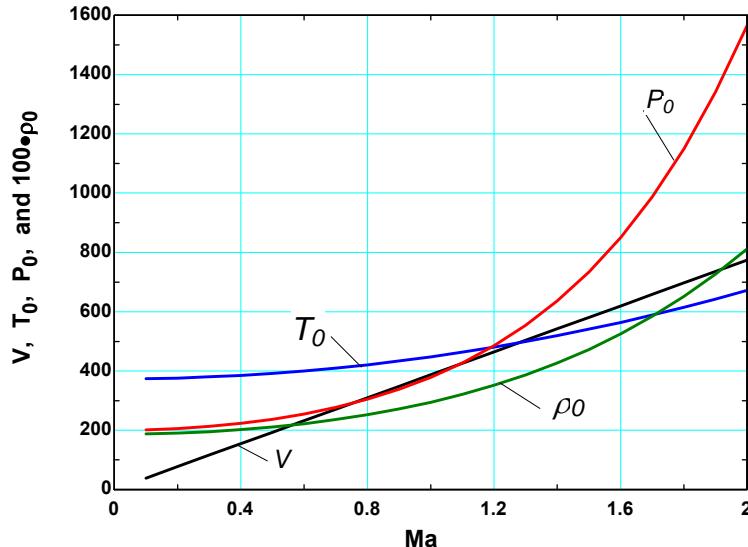

17-45 Problem 17-44 is reconsidered. The effect of Mach number on the velocity and stagnation properties as the Ma is varied from 0.1 to 2 are to be investigated, and the results are to be plotted.

Analysis The EES *Equations* window is printed below, along with the tabulated and plotted results.

```
P=200
T=100+273.15
R=0.287
k=1.4

2.0	774.4	671.7	1564.9	8.118

Discussion Note that as Mach number increases, so does the flow velocity and stagnation temperature, pressure, and density.

17-46 An aircraft is designed to cruise at a given Mach number, elevation, and the atmospheric temperature. The stagnation temperature on the leading edge of the wing is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$.

Analysis The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(236.15 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 308.0 \text{ m/s}$$

Thus,

$$V = Ma \times c = (1.4)(308.0 \text{ m/s}) = 431.2 \text{ m/s}$$

Then,

$$T_0 = T + \frac{V^2}{2c_p} = 236.15 + \frac{(431.2 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 329 \text{ K}$$

Discussion Note that the temperature of a gas increases during a stagnation process as the kinetic energy is converted to enthalpy.

17-47E Air flows through a duct at a specified state and Mach number. The velocity and the stagnation pressure, temperature, and density of the air are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$, $c_p = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ and $k = 1.4$.

Analysis First, $T = 320 + 459.67 = 779.67 \text{ K}$. The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(779.67 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1368.72 \text{ ft/s}$$

Thus,

$$V = Ma \times c = (0.7)(1368.72 \text{ ft/s}) = 958.10 \cong \mathbf{958 \text{ ft/s}}$$

Also,

$$\rho = \frac{P}{RT} = \frac{25 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(779.67 \text{ R})} = 0.086568 \text{ lbm/ft}^3$$

Then the stagnation properties are determined from

$$T_0 = T \left(1 + \frac{(k-1)Ma^2}{2} \right) = (779.67 \text{ R}) \left(1 + \frac{(1.4-1)(0.7)^2}{2} \right) = 856.08 \text{ R} \cong \mathbf{856 \text{ R}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (25 \text{ psia}) \left(\frac{856.08 \text{ R}}{779.67 \text{ R}} \right)^{1.4/(1.4-1)} = 34.678 \text{ psia} \cong \mathbf{34.7 \text{ psia}}$$

$$\rho_0 = \rho \left(\frac{T_0}{T} \right)^{1/(k-1)} = (0.086568 \text{ lbm/ft}^3) \left(\frac{856.08 \text{ R}}{779.67 \text{ R}} \right)^{1/(1.4-1)} = 0.10936 \text{ lbm/ft}^3 \cong \mathbf{0.109 \text{ lbm/ft}^3}$$

Discussion Note that the temperature, pressure, and density of a gas increases during a stagnation process.

Isentropic Flow Through Nozzles

17-48C The fluid would **accelerate even further** instead of decelerating.

Discussion This is the opposite of what would happen in subsonic flow.

17-49C The fluid would **accelerate even further**, as desired.

Discussion This is the opposite of what would happen in subsonic flow.

17-50C (a) The **exit velocity reaches the sonic speed**, (b) the **exit pressure equals the critical pressure**, and (c) the **mass flow rate reaches the maximum value**.

Discussion In such a case, we say that the flow is *choked*.

17-51C (a) **No effect on velocity**. (b) **No effect on pressure**. (c) **No effect on mass flow rate**.

Discussion In this situation, the flow is already choked initially, so further lowering of the back pressure does not change anything upstream of the nozzle exit plane.

17-52C If the back pressure is low enough so that sonic conditions exist at the throats, the mass flow rates in the two nozzles would be identical. However, if the flow is not sonic at the throat, the mass flow rate through the nozzle with the diverging section would be greater, because it acts like a subsonic diffuser.

Discussion Once the flow is choked at the throat, whatever happens downstream is irrelevant to the flow upstream of the throat.

17-53C Maximum flow rate through a converging nozzle is achieved when $Ma = 1$ at the exit of a nozzle. For all other Ma values the mass flow rate decreases. Therefore, the **mass flow rate would decrease if hypersonic velocities were achieved at the throat of a converging nozzle**.

Discussion Note that this is not possible unless the flow upstream of the converging nozzle is already hypersonic.

17-54C Ma^* is the **local velocity non-dimensionalized with respect to the sonic speed at the throat**, whereas Ma is the **local velocity non-dimensionalized with respect to the local sonic speed**.

Discussion The two are identical at the throat when the flow is choked.

17-55C (a) The **velocity decreases**, (b) the **pressure increases**, and (c) the **mass flow rate remains the same**.

Discussion Qualitatively, this is the same as what we are used to (in previous chapters) for incompressible flow.

17-56C No, if the flow in the throat is subsonic. If the velocity at the throat is subsonic, the diverging section would act like a diffuser and decelerate the flow. **Yes, if the flow in the throat is already supersonic,** the diverging section would accelerate the flow to even higher Mach number.

Discussion In duct flow, the latter situation is not possible unless a second converging-diverging portion of the duct is located upstream, and there is sufficient pressure difference to choke the flow in the upstream throat.

17-57 It is to be explained why the maximum flow rate per unit area for a given ideal gas depends only on $P_0 / \sqrt{T_0}$. Also for an ideal gas, a relation is to be obtained for the constant a in $\dot{m}_{\max} / A^* = a(P_0 / \sqrt{T_0})$.

Properties The properties of the ideal gas considered are $R = 0.287 \text{ kPa.m}^3/\text{kg.K}$ and $k = 1.4$.

Analysis The maximum flow rate is given by

$$\dot{m}_{\max} = A^* P_0 \sqrt{k/R T_0} \left(\frac{2}{k+1} \right)^{(k+1)/2(k-1)} \quad \text{or} \quad \dot{m}_{\max} / A^* = \left(P_0 / \sqrt{T_0} \right) \sqrt{k/R} \left(\frac{2}{k+1} \right)^{(k+1)/2(k-1)}$$

For a given gas, k and R are fixed, and thus the mass flow rate depends on the parameter $P_0 / \sqrt{T_0}$. Thus, \dot{m}_{\max} / A^* can be expressed as $\dot{m}_{\max} / A^* = a(P_0 / \sqrt{T_0})$ where

$$a = \sqrt{k/R} \left(\frac{2}{k+1} \right)^{(k+1)/2(k-1)} = \sqrt{\frac{1.4}{(0.287 \text{ kJ/kg.K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}} \left(\frac{2}{1.4+1} \right)^{2.4/0.8} = 0.0404 \text{ (m/s)} \sqrt{\text{K}}$$

Discussion Note that when sonic conditions exist at a throat of known cross-sectional area, the mass flow rate is fixed by the stagnation conditions.

17-58 For an ideal gas, an expression is to be obtained for the ratio of the speed of sound where $\text{Ma} = 1$ to the speed of sound based on the stagnation temperature, c^*/c_0 .

Analysis For an ideal gas the speed of sound is expressed as $c = \sqrt{kRT}$. Thus,

$$\frac{c^*}{c_0} = \frac{\sqrt{kRT^*}}{\sqrt{kRT_0}} = \left(\frac{T^*}{T_0} \right)^{1/2} = \left(\frac{2}{k+1} \right)^{1/2}$$

Discussion Note that a speed of sound changes the flow as the temperature changes.

17-59 Air enters a converging-diverging nozzle at a specified pressure. The back pressure that will result in a specified exit Mach number is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis The stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. It remains constant throughout the nozzle since the flow is isentropic,

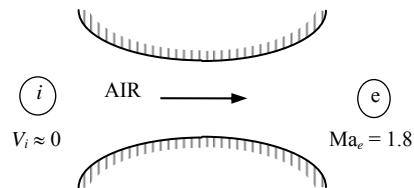

$$P_0 = P_i = 1.2 \text{ MPa}$$

From Table A-32 at $\text{Ma}_e = 1.8$, we read $P_e/P_0 = 0.1740$.

Thus,

$$P = 0.1740P_0 = 0.1740(1.2 \text{ MPa}) = \mathbf{0.209 \text{ MPa}}$$

Discussion If we solve this problem using the relations for compressible isentropic flow, the results would be identical.

17-60 Air enters a nozzle at specified temperature, pressure, and velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of $\text{Ma} = 1$ at the exit.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

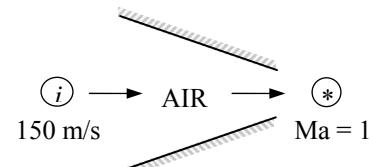

Properties The properties of air are $k = 1.4$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The properties of the fluid at the location where $\text{Ma} = 1$ are the critical properties, denoted by superscript *. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 420 \text{ K} + \frac{(150 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 431.194 \text{ K}$$

and

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (0.6 \text{ MPa}) \left(\frac{431.194 \text{ K}}{420 \text{ K}} \right)^{1.4/(1.4-1)} = 0.65786 \text{ MPa}$$

From Table A-32 (or from Eqs. 17-18 and 17-19) at $\text{Ma} = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$. Thus,

$$T = 0.8333T_0 = 0.8333(431.194 \text{ K}) = 359.31 \text{ K} \approx \mathbf{359 \text{ K}}$$

and

$$P = 0.5283P_0 = 0.5283(0.65786 \text{ MPa}) = 0.34754 \text{ MPa} \approx \mathbf{0.348 \text{ MPa} = 348 \text{ kPa}}$$

Also,

$$c_i = \sqrt{kRT_i} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(420 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 410.799 \text{ m/s}$$

and

$$\text{Ma}_i = \frac{V_i}{c_i} = \frac{150 \text{ m/s}}{410.799 \text{ m/s}} = 0.3651$$

From Table A-32 at this Mach number we read $A_i/A^* = 1.7452$. Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{1.7452} = 0.57300 \approx \mathbf{0.573}$$

Discussion We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

17-61 Air enters a nozzle at specified temperature and pressure with low velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of $\text{Ma} = 1$ at the exit.

Assumptions 1 Air is an ideal gas. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis The properties of the fluid at the location where $\text{Ma} = 1$ are the critical properties, denoted by superscript *. The stagnation temperature and pressure in this case are identical to the inlet temperature and pressure since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i = 350 \text{ K} \quad \text{and} \quad P_0 = P_i = 0.2 \text{ MPa}$$

From Table A-32 (or from Eqs. 17-18 and 17-19) at $\text{Ma} = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$.

Thus,

$$T = 0.8333T_0 = 0.8333(350 \text{ K}) = \mathbf{292 \text{ K}}$$

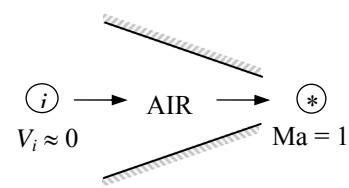

and

$$P = 0.5283P_0 = 0.5283(0.2 \text{ MPa}) = \mathbf{0.106 \text{ MPa}}$$

The Mach number at the nozzle inlet is $\text{Ma} = 0$ since $V_i \approx 0$. From Table A-32 at this Mach number we read $A_i/A^* = \infty$.

Thus the ratio of the throat area to the nozzle inlet area is $\frac{A^*}{A_i} = \frac{1}{\infty} = 0$.

Discussion If we solve this problem using the relations for compressible isentropic flow, the results would be identical.

17-62E Air enters a nozzle at specified temperature, pressure, and velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of $\text{Ma} = 1$ at the exit.

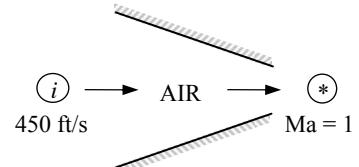

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$ and $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ (Table A-2Ea).

Analysis The properties of the fluid at the location where $\text{Ma} = 1$ are the critical properties, denoted by superscript *. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T + \frac{V_i^2}{2c_p} = 630 \text{ R} + \frac{(450 \text{ ft/s})^2}{2 \times 0.240 \text{ Btu/lbm}\cdot\text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 646.9 \text{ R}$$

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (30 \text{ psia}) \left(\frac{646.9 \text{ K}}{630 \text{ K}} \right)^{1.4/(1.4-1)} = 32.9 \text{ psia}$$

From Table A-32 (or from Eqs. 17-18 and 17-19) at $\text{Ma} = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$.

Thus,

$$T = 0.8333T_0 = 0.8333(646.9 \text{ R}) = \mathbf{539 \text{ R}}$$

and

$$P = 0.5283P_0 = 0.5283(32.9 \text{ psia}) = \mathbf{17.4 \text{ psia}}$$

Also,

$$c_i = \sqrt{kRT_i} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(630 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1230 \text{ ft/s}$$

and

$$\text{Ma}_i = \frac{V_i}{c_i} = \frac{450 \text{ ft/s}}{1230 \text{ ft/s}} = 0.3657$$

From Table A-32 at this Mach number we read $A_i/A^* = 1.7426$. Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{1.7426} = \mathbf{0.574}$$

Discussion If we solve this problem using the relations for compressible isentropic flow, the results would be identical.

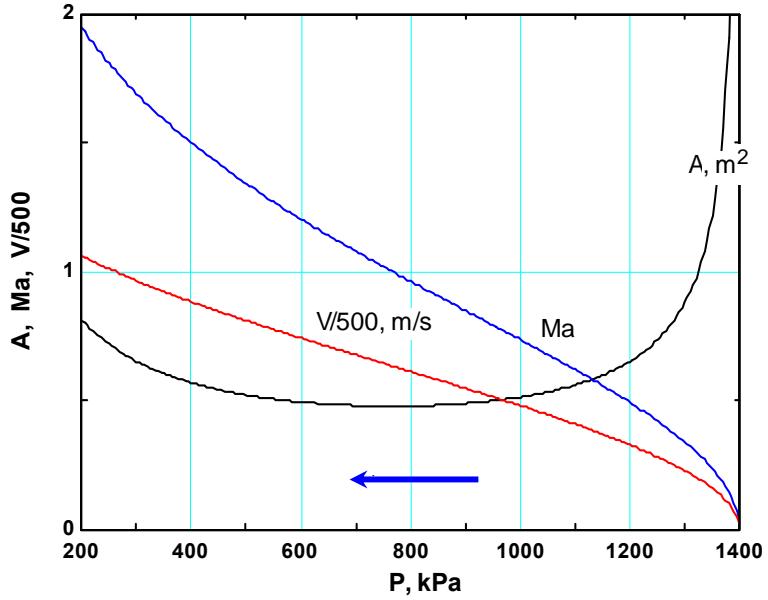

17-63 For subsonic flow at the inlet, the variation of pressure, velocity, and Mach number along the length of the nozzle are to be sketched for an ideal gas under specified conditions.

Assumptions 1 The gas is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The flow is choked at the throat.

Analysis Using EES and CO₂ as the gas, we calculate and plot flow area A , velocity V , and Mach number Ma as the pressure drops from a stagnation value of 1400 kPa to 200 kPa. Note that the curve for A is related to the shape of the nozzle, with horizontal axis serving as the centerline. The EES equation window and the plot are shown below.

```
k=1.289
Cp=0.846 "kJ/kg.K"
R=0.1889 "kJ/kg.K"
P0=1400 "kPa"
```

```
T0=473 "K"
m=3 "kg/s"
rho_0=P0/(R*T0)
rho=P/(R*T)
rho_norm=rho/rho_0 "Normalized density"
T=T0*(P/P0)^((k-1)/k)
Tnorm=T/T0 "Normalized temperature"
V=SQRT(2*Cp*(T0-T)*1000)
V_norm=V/500
A=m/(rho*V)*500
C=SQRT(k*R*T*1000)
Ma=V/C
```

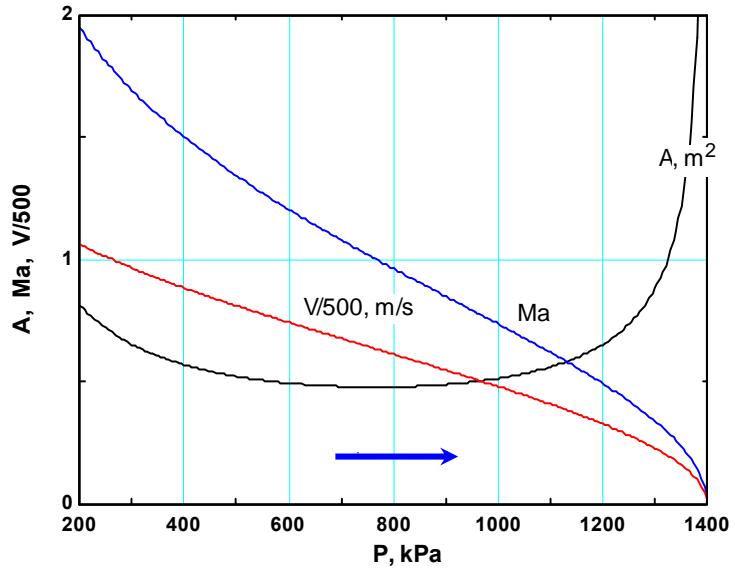

Discussion We are assuming that the back pressure is sufficiently low that the flow is choked at the throat, and the flow downstream of the throat is supersonic without any shock waves. Mach number and velocity continue to rise right through the throat into the diverging portion of the nozzle, since the flow becomes supersonic.

17-64 We repeat the previous problem, but for supersonic flow at the inlet. The variation of pressure, velocity, and Mach number along the length of the nozzle are to be sketched for an ideal gas under specified conditions.

Analysis Using EES and CO₂ as the gas, we calculate and plot flow area A , velocity V , and Mach number Ma as the pressure rises from 200 kPa at a very high velocity to the stagnation value of 1400 kPa. Note that the curve for A is related to the shape of the nozzle, with horizontal axis serving as the centerline.

```
k=1.289
Cp=0.846 "kJ/kg.K"
R=0.1889 "kJ/kg.K"
P0=1400 "kPa"
```

```
T0=473 "K"
m=3 "kg/s"
rho_0=P0/(R*T0)
rho=P/(R*T)
rho_norm=rho/rho_0 "Normalized density"
T=T0*(P/P0)^((k-1)/k)
Tnorm=T/T0 "Normalized temperature"
V=SQRT(2*Cp*(T0-T)*1000)
V_norm=V/500
A=m/(rho*V)*500
C=SQRT(k*R*T*1000)
Ma=V/C
```

Discussion Note that this problem is identical to the proceeding one, except the flow direction is reversed. In fact, when plotted like this, the plots are identical.

17-65 Nitrogen enters a converging-diverging nozzle at a given pressure. The critical velocity, pressure, temperature, and density in the nozzle are to be determined.

Assumptions 1 Nitrogen is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

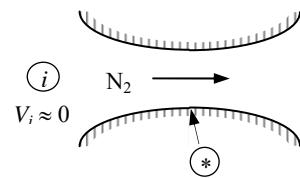

Properties The properties of nitrogen are $k = 1.4$ and $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation pressure in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle,

$$P_0 = P_i = 700 \text{ kPa}$$

$$T_0 = T_i = 400 \text{ K}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{700 \text{ kPa}}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(400 \text{ K})} = 5.896 \text{ kg/m}^3$$

Critical properties are those at a location where the Mach number is $\text{Ma} = 1$. From Table A-32 at $\text{Ma} = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$, and $\rho/\rho_0 = 0.6339$.

Then the critical properties become

$$T^* = 0.8333T_0 = 0.8333(400 \text{ K}) = 333 \text{ K}$$

$$P^* = 0.5283P_0 = 0.5283(700 \text{ kPa}) = 370 \text{ MPa}$$

$$\rho^* = 0.6339\rho_0 = 0.6339(5.896 \text{ kg/m}^3) = 3.74 \text{ kg/m}^3$$

Also,

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.4)(0.2968 \text{ kJ/kg}\cdot\text{K})(333 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 372 \text{ m/s}$$

Discussion We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

17-66 An ideal gas is flowing through a nozzle. The flow area at a location where $\text{Ma} = 2.4$ is specified. The flow area where $\text{Ma} = 1.2$ is to be determined.

Assumptions Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio is given to be $k = 1.4$.

Analysis The flow is assumed to be isentropic, and thus the stagnation and critical properties remain constant throughout the nozzle. The flow area at a location where $\text{Ma}_2 = 1.2$ is determined using A/A^* data from Table A-32 to be

$$\text{Ma}_1 = 2.4 : \frac{A_1}{A^*} = 2.4031 \longrightarrow A^* = \frac{A_1}{2.4031} = \frac{36 \text{ cm}^2}{2.4031} = 14.98 \text{ cm}^2$$

$$\text{Ma}_2 = 1.2 : \frac{A_2}{A^*} = 1.0304 \longrightarrow A_2 = (1.0304)A^* = (1.0304)(14.98 \text{ cm}^2) = 15.4 \text{ cm}^2$$

Discussion We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

17-67 An ideal gas is flowing through a nozzle. The flow area at a location where $Ma = 2.4$ is specified. The flow area where $Ma = 1.2$ is to be determined.

Assumptions Flow through the nozzle is steady, one-dimensional, and isentropic.

Analysis The flow is assumed to be isentropic, and thus the stagnation and critical properties remain constant throughout the nozzle. The flow area at a location where $Ma_2 = 1.2$ is determined using the A/A^* relation,

$$\frac{A}{A^*} = \frac{1}{Ma} \left\{ \left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} Ma^2 \right) \right\}^{(k+1)/2(k-1)}$$

For $k = 1.33$ and $Ma_1 = 2.4$:

$$\frac{A_1}{A^*} = \frac{1}{2.4} \left\{ \left(\frac{2}{1.33+1} \right) \left(1 + \frac{1.33-1}{2} 2.4^2 \right) \right\}^{2.33/2\times0.33} = 2.570$$

and

$$A^* = \frac{A_1}{2.570} = \frac{36 \text{ cm}^2}{2.570} = 14.01 \text{ cm}^2$$

For $k = 1.33$ and $Ma_2 = 1.2$:

$$\frac{A_2}{A^*} = \frac{1}{1.2} \left\{ \left(\frac{2}{1.33+1} \right) \left(1 + \frac{1.33-1}{2} 1.2^2 \right) \right\}^{2.33/2\times0.33} = 1.0316$$

and

$$A_2 = (1.0316)A^* = (1.0316)(14.01 \text{ cm}^2) = \mathbf{14.45 \text{ cm}^2}$$

Discussion Note that the compressible flow functions in Table A-32 are prepared for $k = 1.4$, and thus they cannot be used to solve this problem.

17-68E Air enters a converging-diverging nozzle at a specified temperature and pressure with low velocity. The pressure, temperature, velocity, and mass flow rate are to be calculated in the specified test section.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$ and $R = 0.06855 \text{ Btu/lbm}\cdot\text{R} = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$.

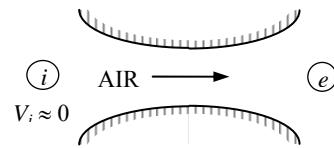

Analysis The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$P_0 = P_i = 150 \text{ psia}$$

and

$$T_0 = T_i = 100^\circ\text{F} \approx 560 \text{ R}$$

Then,

$$T_e = T_0 \left(\frac{2}{2 + (k-1)Ma^2} \right) = (560 \text{ R}) \left(\frac{2}{2 + (1.4-1)2^2} \right) = 311 \text{ R}$$

$$P_e = P_0 \left(\frac{T}{T_0} \right)^{k/(k-1)} = (150 \text{ psia}) \left(\frac{311}{560} \right)^{1.4/0.4} = 19.1 \text{ psia}$$

$$\rho_e = \frac{P_e}{RT_e} = \frac{19.1 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(311 \text{ R})} = 0.166 \text{ lbm}/\text{ft}^3$$

The nozzle exit velocity can be determined from $V_e = Ma_e c_e$, where c_e is the speed of sound at the exit conditions,

$$V_e = Ma_e c_e = Ma_e \sqrt{kRT_e} = (2) \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(311 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1729 \text{ ft/s} \equiv 1730 \text{ ft/s}$$

Finally,

$$\dot{m} = \rho_e A_e V_e = (0.166 \text{ lbm}/\text{ft}^3)(5 \text{ ft}^2)(1729 \text{ ft/s}) = 1435 \text{ lbm/s} \equiv 1440 \text{ lbm/s}$$

Discussion Air must be very dry in this application because the exit temperature of air is extremely low, and any moisture in the air will turn to ice particles.

17-69 Air enters a converging nozzle at a specified temperature and pressure with low velocity. The exit pressure, the exit velocity, and the mass flow rate versus the back pressure are to be calculated and plotted.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

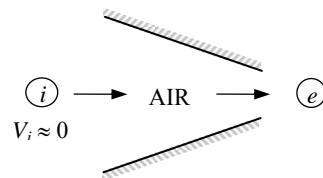

Analysis The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.,

$$P_0 = P_i = 900 \text{ kPa}$$

$$T_0 = T_i = 400 \text{ K}$$

The critical pressure is determined to be

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (900 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/0.4} = 475.5 \text{ kPa}$$

Then the pressure at the exit plane (throat) will be

$$P_e = P_b \quad \text{for} \quad P_b \geq 475.5 \text{ kPa}$$

$$P_e = P^* = 475.5 \text{ kPa} \quad \text{for} \quad P_b < 475.5 \text{ kPa} \quad (\text{choked flow})$$

Thus the back pressure will not affect the flow when $100 < P_b < 475.5 \text{ kPa}$. For a specified exit pressure P_e , the temperature, the velocity and the mass flow rate can be determined from

$$\text{Temperature} \quad T_e = T_0 \left(\frac{P_e}{P_0} \right)^{(k-1)/k} = (400 \text{ K}) \left(\frac{P_e}{900} \right)^{0.4/1.4}$$

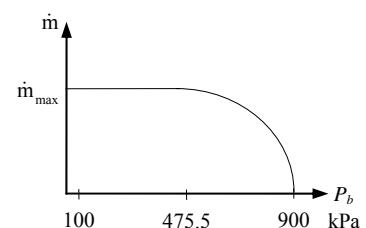

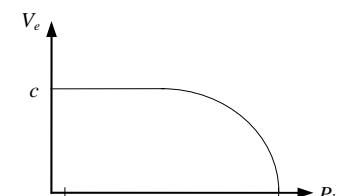

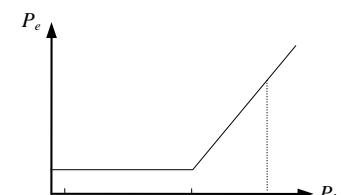

$$\text{Velocity} \quad V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.005 \text{ kJ/kg}\cdot\text{K})(400 - T_e) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.287 \text{ kPa}\cdot\text{m}^3 / \text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.001 \text{ m}^2)$$

The results of the calculations are tabulated as

P_b, kPa	P_e, kPa	T_e, K	$V_e, \text{m/s}$	$\rho_e, \text{kg/m}^3$	$\dot{m}, \text{kg/s}$
900	900	400	0	7.840	0
800	800	386.8	162.9	7.206	1.174
700	700	372.3	236.0	6.551	1.546
600	600	356.2	296.7	5.869	1.741
500	500	338.2	352.4	5.151	1.815
475.5	475.5	333.3	366.2	4.971	1.820
400	475.5	333.3	366.2	4.971	1.820
300	475.5	333.3	366.2	4.971	1.820
200	475.5	333.3	366.2	4.971	1.820
100	475.5	333.3	366.2	4.971	1.820

Discussion We see from the plots that once the flow is choked at a back pressure of 475.5 kPa, the mass flow rate remains constant regardless of how low the back pressure gets.

17-70 We are to reconsider the previous problem. Using EES (or other) software, we are to solve the problem for the inlet conditions of 0.8 MPa and 1200 K.

Analysis Air at 800 kPa, 1200 K enters a converging nozzle with a negligible velocity. The throat area of the nozzle is 10 cm². Assuming isentropic flow, calculate and plot the exit pressure, the exit velocity, and the mass flow rate versus the back pressure P_b for $0.8 \geq P_b \geq 0.1$ MPa.

Discussion We see from the plot that once the flow is choked at a back pressure of 422.7 kPa, the mass flow rate remains constant regardless of how low the back pressure gets.

Shock Waves and Expansion Waves

17-71C No, because the flow must be supersonic before a shock wave can occur. The flow in the converging section of a nozzle is always subsonic.

Discussion A normal shock (if it is to occur) would occur in the supersonic (diverging) section of the nozzle.

17-72C The *Fanno line* represents the **states that satisfy the conservation of mass and energy equations**. The *Rayleigh line* represents the **states that satisfy the conservation of mass and momentum equations**. The *intersections* points of these lines represent the **states that satisfy the conservation of mass, energy, and momentum equations**.

Discussion *T-s* diagrams are quite helpful in understanding these kinds of flows.

17-73C No, the second law of thermodynamics requires the flow after the shock to be subsonic.

Discussion A normal shock wave always goes from supersonic to subsonic in the flow direction.

17-74C (a) velocity decreases, (b) static temperature increases, (c) stagnation temperature remains the same, (d) static pressure increases, and (e) stagnation pressure decreases.

Discussion In addition, the Mach number goes from supersonic ($Ma > 1$) to subsonic ($Ma < 1$).

17-75C *Oblique shocks* occur when a gas flowing at supersonic speeds strikes a flat or inclined surface. Normal shock waves are perpendicular to flow whereas inclined shock waves, as the name implies, are typically **inclined relative to the flow direction**. Also, normal shocks form a straight line whereas **oblique shocks can be straight or curved**, depending on the surface geometry.

Discussion In addition, while a normal shock must go from supersonic ($Ma > 1$) to subsonic ($Ma < 1$), the Mach number downstream of an oblique shock can be either supersonic or subsonic.

17-76C Yes, the *upstream flow* has to be supersonic for an oblique shock to occur. **No**, the flow *downstream* of an oblique shock can be subsonic, sonic, and even supersonic.

Discussion The latter is not true for normal shocks. For a normal shock, the flow must always go from supersonic ($Ma > 1$) to subsonic ($Ma < 1$).

17-77C Yes, the claim is correct. Conversely, normal shocks can be thought of as special oblique shocks in which the shock angle is $\beta = \pi/2$, or 90° .

Discussion The component of flow in the direction normal to the oblique shock acts exactly like a normal shock. We can think of the flow parallel to the oblique shock as “going along for the ride” – it does not affect anything.

17-78C When the wedge half-angle δ is greater than the maximum deflection angle θ_{\max} , the shock becomes curved and detaches from the nose of the wedge, forming what is called a *detached oblique shock* or a *bow wave*. The numerical value of the shock angle at the nose is $\beta = 90^\circ$.

Discussion When δ is less than θ_{\max} , the oblique shock is attached to the nose.

17-79C When supersonic flow impinges on a blunt body like the rounded nose of an aircraft, the wedge half-angle δ at the nose is 90° , and an attached oblique shock cannot exist, regardless of Mach number. Therefore, **a detached oblique shock must occur in front of all such blunt-nosed bodies**, whether two-dimensional, axisymmetric, or fully three-dimensional.

Discussion Since $\delta = 90^\circ$ at the nose, δ is always greater than θ_{\max} , regardless of Ma or the shape of the rest of the body.

17-80C The isentropic relations of ideal gases are **not applicable for flows across (a) normal shock waves and (b) oblique shock waves**, but they **are applicable for flows across (c) Prandtl-Meyer expansion waves**.

Discussion Flow across any kind of shock wave involves irreversible losses – hence, it cannot be isentropic.

17-81 Air flowing through a nozzle experiences a normal shock. Various properties are to be calculated before and after the shock.

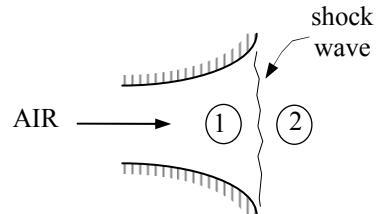

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air at room temperature are $k = 1.4$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation temperature and pressure before the shock are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 205 + \frac{(740 \text{ m/s})^2}{2(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 477.4 \text{ K}$$

$$P_{01} = P_1 \left(\frac{T_{01}}{T_1} \right)^{k/(k-1)} = (18 \text{ kPa}) \left(\frac{477.4 \text{ K}}{205 \text{ K}} \right)^{1.4/(1.4-1)} = 347.0 \text{ kPa}$$

The velocity and the Mach number before the shock are determined from

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(205 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = \mathbf{287.0 \text{ m/s}}$$

and

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{740 \text{ m/s}}{287.0 \text{ m/s}} = \mathbf{2.578}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $\text{Ma}_1 = 2.578$ we read (We obtained the following values using analytical relations in Table A-33.)

$$\text{Ma}_2 = \mathbf{0.5058}, \quad \frac{P_{02}}{P_1} = 9.0349, \quad \frac{P_2}{P_1} = 7.5871, \quad \text{and} \quad \frac{T_2}{T_1} = 2.2158$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 9.0349P_1 = (9.0349)(18 \text{ kPa}) = \mathbf{162.6 \text{ kPa}}$$

$$P_2 = 7.5871P_1 = (7.5871)(18 \text{ kPa}) = \mathbf{136.6 \text{ kPa}}$$

$$T_2 = 2.2158T_1 = (2.2158)(205 \text{ K}) = \mathbf{454.2 \text{ K}}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.5058) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(454.2 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = \mathbf{216.1 \text{ m/s}}$$

Discussion This problem could also be solved using the relations for compressible flow and normal shock functions. The results would be identical.

17-82 Air flowing through a nozzle experiences a normal shock. The entropy change of air across the normal shock wave is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The entropy change across the shock is determined to be

$$\begin{aligned}s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\&= (1.005 \text{ kJ/kg}\cdot\text{K})\ln(2.2158) - (0.287 \text{ kJ/kg}\cdot\text{K})\ln(7.5871) \\&= \mathbf{0.2180 \text{ kJ/kg}\cdot\text{K}}\end{aligned}$$

Discussion A shock wave is a highly dissipative process, and the entropy generation is large during shock waves.

17-83 Air flowing through a converging-diverging nozzle experiences a normal shock at the exit. The effect of the shock wave on various properties is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs. 3 The shock wave occurs at the exit plane.

Properties The properties of air are $k = 1.4$ and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

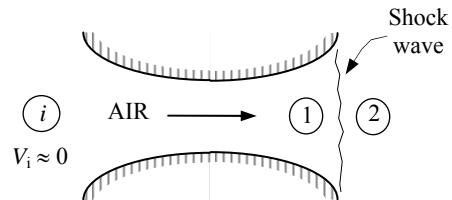

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Then,

$$P_{01} = P_i = 1 \text{ MPa}$$

$$T_{01} = T_i = 300 \text{ K}$$

Then,

$$T_1 = T_{01} \left(\frac{2}{2 + (k-1)Ma_1^2} \right) = (300 \text{ K}) \left(\frac{2}{2 + (1.4-1)2.4^2} \right) = 139.4 \text{ K}$$

and

$$P_1 = P_{01} \left(\frac{T_1}{T_0} \right)^{k/(k-1)} = (1 \text{ MPa}) \left(\frac{139.4}{300} \right)^{1.4/0.4} = 0.06840 \text{ MPa}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $Ma_1 = 2.4$ we read

$$Ma_2 = 0.5231 \approx \mathbf{0.523}, \quad \frac{P_{02}}{P_{01}} = 0.5401, \quad \frac{P_2}{P_1} = 6.5533, \quad \text{and} \quad \frac{T_2}{T_1} = 2.0403$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 0.5401P_{01} = (0.5401)(1.0 \text{ MPa}) = \mathbf{0.540 \text{ MPa} = 540 \text{ kPa}}$$

$$P_2 = 6.5533P_1 = (6.5533)(0.06840 \text{ MPa}) = \mathbf{0.448 \text{ MPa} = 448 \text{ kPa}}$$

$$T_2 = 2.0403T_1 = (2.0403)(139.4 \text{ K}) = \mathbf{284 \text{ K}}$$

The air velocity after the shock can be determined from $V_2 = Ma_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = Ma_2 c_2 = Ma_2 \sqrt{kRT_2} = (0.5231) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(284 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{177 \text{ m/s}}$$

Discussion We can also solve this problem using the relations for normal shock functions. The results would be identical.

17-84 Air enters a converging-diverging nozzle at a specified state. The required back pressure that produces a normal shock at the exit plane is to be determined for the specified nozzle geometry.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs. 3 The shock wave occurs at the exit plane.

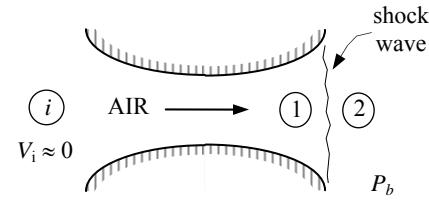

Analysis The inlet stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. Since the flow before the shock to be isentropic,

$$P_{01} = P_i = 2 \text{ MPa}$$

It is specified that $A/A^* = 3.5$. From Table A-32, Mach number and the pressure ratio which corresponds to this area ratio are the $Ma_1 = 2.80$ and $P_1/P_{01} = 0.0368$. The pressure ratio across the shock for this Ma_1 value is, from Table A-33, $P_2/P_1 = 8.98$. Thus the back pressure, which is equal to the static pressure at the nozzle exit, must be

$$P_2 = 8.98P_1 = 8.98 \times 0.0368P_{01} = 8.98 \times 0.0368 \times (2 \text{ MPa}) = \mathbf{0.661 \text{ MPa}}$$

Discussion We can also solve this problem using the relations for compressible flow and normal shock functions. The results would be identical.

17-85 Air enters a converging-diverging nozzle at a specified state. The required back pressure that produces a normal shock at the exit plane is to be determined for the specified nozzle geometry.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

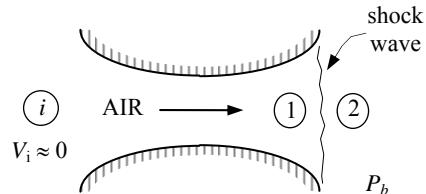

Analysis The inlet stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. Since the flow before the shock to be isentropic,

$$P_{0x} = P_i = 2 \text{ MPa}$$

It is specified that $A/A^* = 2$. From Table A-32, the Mach number and the pressure ratio which corresponds to this area ratio are the $Ma_1 = 2.20$ and $P_1/P_{01} = 0.0935$. The pressure ratio across the shock for this M_1 value is, from Table A-33, $P_2/P_1 = 5.48$. Thus the back pressure, which is equal to the static pressure at the nozzle exit, must be

$$P_2 = 5.48P_1 = 5.48 \times 0.0935P_{01} = 5.48 \times 0.0935 \times (2 \text{ MPa}) = \mathbf{1.02 \text{ MPa}}$$

Discussion We can also solve this problem using the relations for compressible flow and normal shock functions. The results would be identical.

17-86 Air flowing through a nozzle experiences a normal shock. The effect of the shock wave on various properties is to be determined. Analysis is to be repeated for helium under the same conditions.

Assumptions 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $k = 1.4$ and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and the properties of helium are $k = 1.667$ and $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$.

Analysis The air properties upstream the shock are

$$\text{Ma}_1 = 3.2, P_1 = 58 \text{ kPa}, \text{ and } T_1 = 270 \text{ K}$$

Fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions in Table A-33. For $\text{Ma}_1 = 3.2$,

$$\text{Ma}_2 = \mathbf{0.4643}, \frac{P_{02}}{P_1} = 13.656, \frac{P_2}{P_1} = 11.780, \text{ and } \frac{T_2}{T_1} = 2.9220$$

We obtained these values using analytical relations in Table A-33. Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 13.656P_1 = (13.656)(58 \text{ kPa}) = \mathbf{792.0 \text{ kPa}}$$

$$P_2 = 11.780P_1 = (11.780)(58 \text{ kPa}) = \mathbf{683.2 \text{ kPa}}$$

$$T_2 = 2.9220T_1 = (2.9220)(270 \text{ K}) = \mathbf{788.9 \text{ K}}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.4643) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(788.9 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{261.4 \text{ m/s}}$$

We now repeat the analysis for helium. This time we cannot use the tabulated values in Table A-33 since k is not 1.4. Therefore, we have to calculate the desired quantities using the analytical relations,

$$\text{Ma}_2 = \left(\frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k / (k-1) - 1} \right)^{1/2} = \left(\frac{3.2^2 + 2/(1.667-1)}{2 \times 3.2^2 \times 1.667 / (1.667-1) - 1} \right)^{1/2} = \mathbf{0.5136}$$

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} = \frac{1 + 1.667 \times 3.2^2}{1 + 1.667 \times 0.5136^2} = 12.551$$

$$\frac{T_2}{T_1} = \frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2} = \frac{1 + 3.2^2(1.667-1)/2}{1 + 0.5136^2(1.667-1)/2} = 4.0580$$

$$\begin{aligned} \frac{P_{02}}{P_1} &= \left(\frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right) \left(1 + (k-1)\text{Ma}_2^2/2 \right)^{k/(k-1)} \\ &= \left(\frac{1 + 1.667 \times 3.2^2}{1 + 1.667 \times 0.5136^2} \right) \left(1 + (1.667-1) \times 0.5136^2/2 \right)^{1.667/0.667} = 15.495 \end{aligned}$$

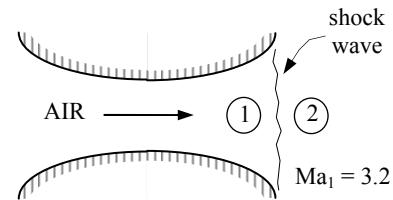

$$\text{Thus, } P_{02} = 15.495P_1 = (15.495)(58 \text{ kPa}) = \mathbf{898.7 \text{ kPa}}$$

$$P_2 = 12.551P_1 = (12.551)(58 \text{ kPa}) = \mathbf{728.0 \text{ kPa}}$$

$$T_2 = 4.0580T_1 = (4.0580)(270 \text{ K}) = \mathbf{1096 \text{ K}}$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_y} = (0.5136) \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(1096 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{1000 \text{ m/s}}$$

Discussion The velocity and Mach number are higher for helium than for air due to the different values of k and R .

17-87 Air flowing through a nozzle experiences a normal shock. The entropy change of air across the normal shock wave is to be determined.

Assumptions 1 Air and helium are ideal gases with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and the properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$.

Analysis The entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (1.005 \text{ kJ/kg}\cdot\text{K}) \ln(2.9220) - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(11.780) = \mathbf{0.370 \text{ kJ/kg}\cdot\text{K}}$$

For helium, the entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (5.1926 \text{ kJ/kg}\cdot\text{K}) \ln(4.0580) - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln(12.551) = \mathbf{2.02 \text{ kJ/kg}\cdot\text{K}}$$

Discussion Note that shock wave is a highly dissipative process, and the entropy generation is large during shock waves.

17-88E Air flowing through a nozzle experiences a normal shock. Effect of the shock wave on various properties is to be determined. Analysis is to be repeated for helium

Assumptions 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

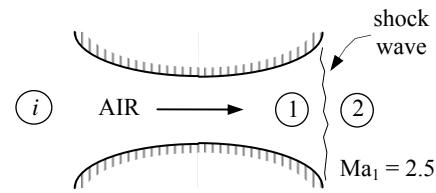

Properties The properties of air are $k = 1.4$ and $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$, and the properties of helium are $k = 1.667$ and $R = 0.4961 \text{ Btu/lbm}\cdot\text{R}$.

Analysis The air properties upstream the shock are

$$\text{Ma}_1 = 2.5, P_1 = 10 \text{ psia}, \text{ and } T_1 = 440.5 \text{ R}$$

Fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $\text{Ma}_1 = 2.5$,

$$\text{Ma}_2 = 0.513, \frac{P_{02}}{P_1} = 8.5262, \frac{P_2}{P_1} = 7.125, \text{ and } \frac{T_2}{T_1} = 2.1375$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 8.5262P_1 = (8.5262)(10 \text{ psia}) = 85.3 \text{ psia}$$

$$P_2 = 7.125P_1 = (7.125)(10 \text{ psia}) = 71.3 \text{ psia}$$

$$T_2 = 2.1375T_1 = (2.1375)(440.5 \text{ R}) = 942 \text{ R}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.513) \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(941.6 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 772 \text{ ft/s}$$

We now repeat the analysis for helium. This time we cannot use the tabulated values in Table A-33 since k is not 1.4. Therefore, we have to calculate the desired quantities using the analytical relations,

$$\text{Ma}_2 = \left(\frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k / (k-1) - 1} \right)^{1/2} = \left(\frac{2.5^2 + 2/(1.667-1)}{2 \times 2.5^2 \times 1.667 / (1.667-1) - 1} \right)^{1/2} = 0.553$$

$$\frac{P_2}{P_1} = \frac{1+k\text{Ma}_1^2}{1+k\text{Ma}_2^2} = \frac{1+1.667 \times 2.5^2}{1+1.667 \times 0.553^2} = 7.5632$$

$$\frac{T_2}{T_1} = \frac{1+\text{Ma}_1^2(k-1)/2}{1+\text{Ma}_2^2(k-1)/2} = \frac{1+2.5^2(1.667-1)/2}{1+0.553^2(1.667-1)/2} = 2.7989$$

$$\begin{aligned} \frac{P_{02}}{P_1} &= \left(\frac{1+k\text{Ma}_1^2}{1+k\text{Ma}_2^2} \right) \left(1 + (k-1)\frac{\text{Ma}_2^2}{2} \right)^{k/(k-1)} \\ &= \left(\frac{1+1.667 \times 2.5^2}{1+1.667 \times 0.553^2} \right) \left(1 + (1.667-1) \times 0.553^2 / 2 \right)^{1.667/0.667} = 9.641 \end{aligned}$$

$$\text{Thus, } P_{02} = 11.546P_1 = (11.546)(10 \text{ psia}) = 115 \text{ psia}$$

$$P_2 = 7.5632P_1 = (7.5632)(10 \text{ psia}) = 75.6 \text{ psia}$$

$$T_2 = 2.7989T_1 = (2.7989)(440.5 \text{ R}) = 1233 \text{ R}$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.553) \sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(1233.9 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 2794 \text{ ft/s}$$

Discussion This problem could also be solved using the relations for compressible flow and normal shock functions. The results would be identical.

17-89E We are to reconsider Prob. 17-88E. Using EES (or other) software, we are to study the effects of both air and helium flowing steadily in a nozzle when there is a normal shock at a Mach number in the range $2 < M_x < 3.5$. In addition to the required information, we are to calculate the entropy change of the air and helium across the normal shock, and tabulate the results in a parametric table.

Analysis We use EES to calculate the entropy change of the air and helium across the normal shock. The results are given in the Parametric Table for $2 < M_x < 3.5$.

```

Discussion In all cases, regardless of the fluid or the Mach number, entropy increases across a shock wave. This is because a shock wave involves irreversibilities.

17-90 For an ideal gas flowing through a normal shock, a relation for V_2/V_1 in terms of k , Ma_1 , and Ma_2 is to be developed.

Analysis The conservation of mass relation across the shock is $\rho_1 V_1 = \rho_2 V_2$ and it can be expressed as

$$\frac{V_2}{V_1} = \frac{\rho_1}{\rho_2} = \frac{P_1 / RT_1}{P_2 / RT_2} = \left(\frac{P_1}{P_2} \right) \left(\frac{T_2}{T_1} \right)$$

From Eqs. 17-35 and 17-38,

$$\frac{V_2}{V_1} = \left(\frac{1 + k\text{Ma}_2^2}{1 + k\text{Ma}_1^2} \right) \left(\frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2} \right)$$

Discussion This is an important relation as it enables us to determine the velocity ratio across a normal shock when the Mach numbers before and after the shock are known.

17-91 The entropy change of air across the shock for upstream Mach numbers between 0.5 and 1.5 is to be determined and plotted.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $k = 1.4$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The entropy change across the shock is determined to be

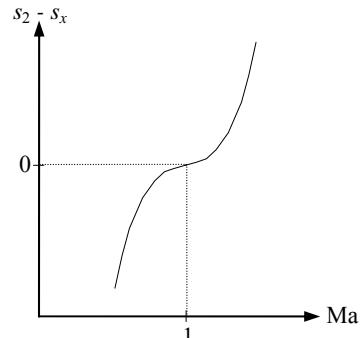

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$$

where

$$\text{Ma}_2 = \left(\frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k/(k-1)-1} \right)^{1/2}, \quad \frac{P_2}{P_1} = \frac{1+k\text{Ma}_1^2}{1+k\text{Ma}_2^2}, \quad \text{and} \quad \frac{T_2}{T_1} = \frac{1+\text{Ma}_1^2(k-1)/2}{1+\text{Ma}_2^2(k-1)/2}$$

The results of the calculations can be tabulated as

Ma_1	Ma_2	T_2/T_1	P_2/P_1	$s_2 - s_1$
0.5	2.6458	0.1250	0.4375	-1.853
0.6	1.8778	0.2533	0.6287	-1.247
0.7	1.5031	0.4050	0.7563	-0.828
0.8	1.2731	0.5800	0.8519	-0.501
0.9	1.1154	0.7783	0.9305	-0.231
1.0	1.0000	1.0000	1.0000	0.0
1.1	0.9118	1.0649	1.2450	0.0003
1.2	0.8422	1.1280	1.5133	0.0021
1.3	0.7860	1.1909	1.8050	0.0061
1.4	0.7397	1.2547	2.1200	0.0124
1.5	0.7011	1.3202	2.4583	0.0210

Discussion The total entropy change is negative for upstream Mach numbers Ma_1 less than unity. Therefore, normal shocks cannot occur when $\text{Ma}_1 < 1$.

17-92 Supersonic airflow approaches the nose of a two-dimensional wedge and undergoes a straight oblique shock. For a specified Mach number, the minimum shock angle and the maximum deflection angle are to be determined.

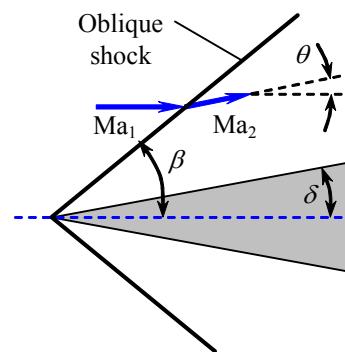

Assumptions Air is an ideal gas with a constant specific heat ratio of $k = 1.4$ (so that Fig. 17-41 is applicable).

Analysis For $Ma = 5$, we read from Fig. 17-41

$$\text{Minimum shock (or wave) angle: } \beta_{\min} = 12^\circ$$

$$\text{Maximum deflection (or turning) angle: } \theta_{\max} = 41.5^\circ$$

Discussion Note that the minimum shock angle decreases and the maximum deflection angle increases with increasing Mach number Ma_1 .

17-93E Air flowing at a specified supersonic Mach number is forced to undergo a compression turn (an oblique shock). The Mach number, pressure, and temperature downstream of the oblique shock are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e., $\theta \approx \delta = 15^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 15^\circ = \frac{2(2^2 \sin^2 \beta - 1) / \tan \beta}{2^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 45.34^\circ$ and $\beta_{\text{strong}} = 79.83^\circ$. Then the upstream “normal” Mach number $\text{Ma}_{1,n}$ becomes

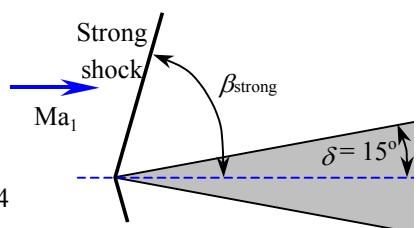

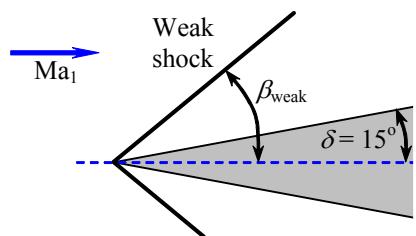

$$\text{Weak shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 45.34^\circ = 1.423$$

$$\text{Strong shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 79.83^\circ = 1.969$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Weak shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.423)^2 + 2}{2(1.4)(1.423)^2 - 1.4 + 1}} = 0.7304$$

$$\text{Strong shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.969)^2 + 2}{2(1.4)(1.969)^2 - 1.4 + 1}} = 0.5828$$

The downstream pressure and temperature for each case are determined to be

$$\text{Weak shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (6 \text{ psia}) \frac{2(1.4)(1.423)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{13.2 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (480 \text{ R}) \frac{13.2 \text{ psia}}{6 \text{ psia}} \frac{2 + (1.4-1)(1.423)^2}{(1.4+1)(1.423)^2} = \mathbf{609 \text{ R}}$$

$$\text{Strong shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (6 \text{ psia}) \frac{2(1.4)(1.969)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{26.1 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (480 \text{ R}) \frac{26.1 \text{ psia}}{6 \text{ psia}} \frac{2 + (1.4-1)(1.969)^2}{(1.4+1)(1.969)^2} = \mathbf{798 \text{ R}}$$

The downstream Mach number is determined to be

$$\text{Weak shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.7304}{\sin(45.34^\circ - 15^\circ)} = \mathbf{1.45}$$

$$\text{Strong shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.5828}{\sin(79.83^\circ - 15^\circ)} = \mathbf{0.644}$$

Discussion Note that the change in Mach number, pressure, temperature across the *strong shock* are much greater than the changes across the *weak shock*, as expected. For both the weak and strong oblique shock cases, $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ is subsonic. However, Ma_2 is *supersonic* across the weak oblique shock, but *subsonic* across the strong oblique shock.

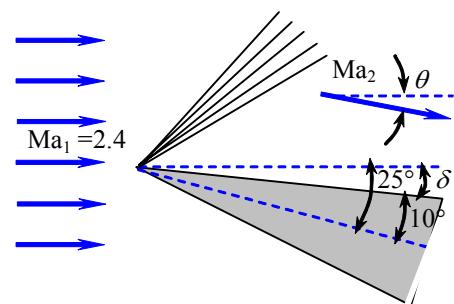

17-94 Air flowing at a specified supersonic Mach number undergoes an expansion turn over a tilted wedge. The Mach number, pressure, and temperature downstream of the sudden expansion above the wedge are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, the deflection angle is determined to be $\theta \approx \delta = 25^\circ - 10^\circ = 15^\circ$. Then the upstream and downstream Prandtl-Meyer functions are determined to be

$$\nu(\text{Ma}) = \sqrt{\frac{k+1}{k-1}} \tan^{-1} \left(\sqrt{\frac{k-1}{k+1} (\text{Ma}^2 - 1)} \right) - \tan^{-1} \left(\sqrt{\text{Ma}^2 - 1} \right)$$

Upstream:

$$\nu(\text{Ma}_1) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} (2.4^2 - 1)} \right) - \tan^{-1} \left(\sqrt{2.4^2 - 1} \right) = 36.75^\circ$$

Then the downstream Prandtl-Meyer function becomes

$$\nu(\text{Ma}_2) = \theta + \nu(\text{Ma}_1) = 15^\circ + 36.75^\circ = 51.75^\circ$$

Now Ma_2 is found from the Prandtl-Meyer relation, which is now implicit:

$$\text{Downstream: } \nu(\text{Ma}_2) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} (\text{Ma}_2^2 - 1)} \right) - \tan^{-1} \left(\sqrt{\text{Ma}_2^2 - 1} \right) = 51.75^\circ$$

It gives $\text{Ma}_2 = 3.105$. Then the downstream pressure and temperature are determined from the isentropic flow relations

$$P_2 = \frac{P_2 / P_0}{P_1 / P_0} P_1 = \frac{[1 + \text{Ma}_2^2(k-1)/2]^{-k/(k-1)}}{[1 + \text{Ma}_1^2(k-1)/2]^{-k/(k-1)}} P_1 = \frac{[1 + 3.105^2(1.4-1)/2]^{-1.4/0.4}}{[1 + 2.4^2(1.4-1)/2]^{-1.4/0.4}} (70 \text{ kPa}) = 23.8 \text{ kPa}$$

$$T_2 = \frac{T_2 / T_0}{T_1 / T_0} T_1 = \frac{[1 + \text{Ma}_2^2(k-1)/2]^{-1}}{[1 + \text{Ma}_1^2(k-1)/2]^{-1}} T_1 = \frac{[1 + 3.105^2(1.4-1)/2]^{-1}}{[1 + 2.4^2(1.4-1)/2]^{-1}} (260 \text{ K}) = 191 \text{ K}$$

Note that this is an expansion, and Mach number increases while pressure and temperature decrease, as expected.

Discussion There are compressible flow calculators on the Internet that solve these implicit equations that arise in the analysis of compressible flow, along with both normal and oblique shock equations; e.g., see www.aoe.vt.edu/~devenpor/aoe3114/calc.html.

17-95 Air flowing at a specified supersonic Mach number undergoes a compression turn (an oblique shock) over a tilted wedge. The Mach number, pressure, and temperature downstream of the shock below the wedge are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, the deflection angle is determined to be $\theta \approx \delta = 25^\circ + 10^\circ = 35^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2(k + \cos 2\beta) + 2} \rightarrow \tan 12^\circ = \frac{2(3.4^2 \sin^2 \beta - 1) / \tan \beta}{3.4^2(1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 49.86^\circ$ and $\beta_{\text{strong}} = 77.66^\circ$. Then for the case of strong oblique shock, the upstream “normal” Mach number $\text{Ma}_{1,n}$ becomes

$$\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 5 \sin 77.66^\circ = 4.884$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(4.884)^2 + 2}{2(1.4)(4.884)^2 - 1.4 + 1}} = 0.4169$$

The downstream pressure and temperature are determined to be

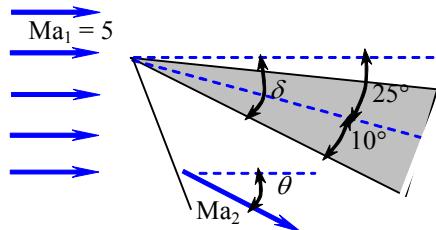

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (70 \text{ kPa}) \frac{2(1.4)(4.884)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{1940 \text{ kPa}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (260 \text{ K}) \frac{1940 \text{ kPa}}{70 \text{ kPa}} \frac{2 + (1.4-1)(4.884)^2}{(1.4+1)(4.884)^2} = \mathbf{1450 \text{ K}}$$

The downstream Mach number is determined to be

$$\text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.4169}{\sin(77.66^\circ - 35^\circ)} = \mathbf{0.615}$$

Discussion Note that $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ and Ma_2 are subsonic. Also note the huge rise in temperature and pressure across the strong oblique shock, and the challenges they present for spacecraft during reentering the earth's atmosphere.

17-96E Air flowing at a specified supersonic Mach number is forced to turn upward by a ramp, and weak oblique shock forms. The wave angle, Mach number, pressure, and temperature after the shock are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the ramp, i.e., $\theta \approx \delta = 8^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(Ma_1^2 \sin^2 \beta - 1) / \tan \beta}{Ma_1^2(k + \cos 2\beta) + 2} \rightarrow \tan 8^\circ = \frac{2(2^2 \sin^2 \beta - 1) / \tan \beta}{2^2(1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 37.21^\circ$ and $\beta_{\text{strong}} = 85.05^\circ$. Then for the case of weak oblique shock, the upstream “normal” Mach number $Ma_{1,n}$ becomes

$$Ma_{1,n} = Ma_1 \sin \beta = 2 \sin 37.21^\circ = 1.209$$

Also, the downstream normal Mach numbers $Ma_{2,n}$ become

$$Ma_{2,n} = \sqrt{\frac{(k-1)Ma_{1,n}^2 + 2}{2kMa_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.209)^2 + 2}{2(1.4)(1.209)^2 - 1.4 + 1}} = 0.8363$$

The downstream pressure and temperature are determined to be

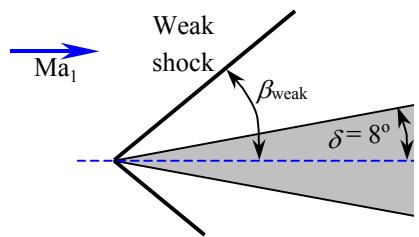

$$P_2 = P_1 \frac{2kMa_{1,n}^2 - k + 1}{k + 1} = (12 \text{ psia}) \frac{2(1.4)(1.209)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{18.5 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)Ma_{1,n}^2}{(k+1)Ma_{1,n}^2} = (490 \text{ R}) \frac{18.5 \text{ psia}}{12 \text{ psia}} \frac{2 + (1.4-1)(1.209)^2}{(1.4+1)(1.209)^2} = \mathbf{556 \text{ R}}$$

The downstream Mach number is determined to be

$$Ma_2 = \frac{Ma_{2,n}}{\sin(\beta - \theta)} = \frac{0.8363}{\sin(37.21^\circ - 8^\circ)} = \mathbf{1.71}$$

Discussion Note that $Ma_{1,n}$ is supersonic and $Ma_{2,n}$ is subsonic. However, Ma_2 is *supersonic* across the weak oblique shock (it is *subsonic* across the strong oblique shock).

17-97 Air flowing at a specified supersonic Mach number undergoes an expansion turn. The Mach number, pressure, and temperature downstream of the sudden expansion along a wall are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e., $\theta \approx \delta = 15^\circ$. Then the upstream and downstream Prandtl-Meyer functions are determined to be

$$\nu(\text{Ma}) = \sqrt{\frac{k+1}{k-1}} \tan^{-1} \left(\sqrt{\frac{k-1}{k+1} (\text{Ma}^2 - 1)} \right) - \tan^{-1} \left(\sqrt{\text{Ma}^2 - 1} \right)$$

Upstream:

$$\nu(\text{Ma}_1) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} (3.6^2 - 1)} \right) - \tan^{-1} \left(\sqrt{3.6^2 - 1} \right) = 60.09^\circ$$

Then the downstream Prandtl-Meyer function becomes

$$\nu(\text{Ma}_2) = \theta + \nu(\text{Ma}_1) = 15^\circ + 60.09^\circ = 75.09^\circ$$

Ma_2 is found from the Prandtl-Meyer relation, which is now implicit:

$$\text{Downstream: } \nu(\text{Ma}_2) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} \text{Ma}_2^2 - 1} \right) - \tan^{-1} \left(\sqrt{\text{Ma}_2^2 - 1} \right) = 75.09^\circ$$

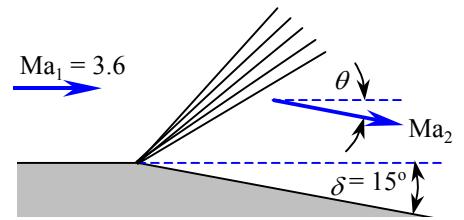

Solution of this implicit equation gives $\text{Ma}_2 = 4.81$. Then the downstream pressure and temperature are determined from the isentropic flow relations:

$$P_2 = \frac{P_2 / P_0}{P_1 / P_0} P_1 = \frac{[1 + \text{Ma}_2^2 (k-1)/2]^{-k/(k-1)}}{[1 + \text{Ma}_1^2 (k-1)/2]^{-k/(k-1)}} P_1 = \frac{[1 + 4.81^2 (1.4-1)/2]^{-1.4/0.4}}{[1 + 3.6^2 (1.4-1)/2]^{-1.4/0.4}} (40 \text{ kPa}) = 8.31 \text{ kPa}$$

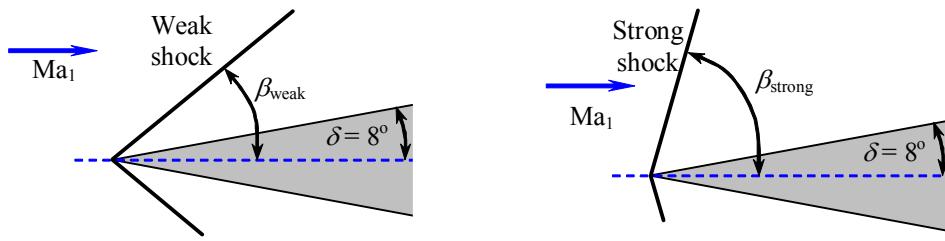

$$T_2 = \frac{T_2 / T_0}{T_1 / T_0} T_1 = \frac{[1 + \text{Ma}_2^2 (k-1)/2]^{-1}}{[1 + \text{Ma}_1^2 (k-1)/2]^{-1}} T_1 = \frac{[1 + 4.81^2 (1.4-1)/2]^{-1}}{[1 + 3.6^2 (1.4-1)/2]^{-1}} (280 \text{ K}) = 179 \text{ K}$$

Note that this is an expansion, and Mach number increases while pressure and temperature decrease, as expected.

Discussion There are compressible flow calculators on the Internet that solve these implicit equations that arise in the analysis of compressible flow, along with both normal and oblique shock equations; e.g., see www.aoe.vt.edu/~devenpor/aoe3114/calc.html.

17-98 Air flowing at a specified supersonic Mach number impinges on a two-dimensional wedge. The shock angle, Mach number, and pressure downstream of the weak and strong oblique shock formed by a wedge are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e., $\theta \approx \delta = 8^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 8^\circ = \frac{2(3.4^2 \sin^2 \beta - 1) / \tan \beta}{3.4^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 23.15^\circ$ and $\beta_{\text{strong}} = 87.45^\circ$. Then the upstream "normal" Mach number $\text{Ma}_{1,n}$ becomes

$$\text{Weak shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 3.4 \sin 23.15^\circ = 1.336$$

$$\text{Strong shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 3.4 \sin 87.45^\circ = 3.397$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Weak shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.336)^2 + 2}{2(1.4)(1.336)^2 - 1.4 + 1}} = 0.7681$$

$$\text{Strong shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(3.397)^2 + 2}{2(1.4)(3.397)^2 - 1.4 + 1}} = 0.4553$$

The downstream pressure for each case is determined to be

$$\text{Weak shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (60 \text{ kPa}) \frac{2(1.4)(1.336)^2 - 1.4 + 1}{1.4 + 1} = 115.0 \text{ kPa}$$

$$\text{Strong shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (60 \text{ kPa}) \frac{2(1.4)(3.397)^2 - 1.4 + 1}{1.4 + 1} = 797.6 \text{ kPa}$$

The downstream Mach number is determined to be

$$\text{Weak shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.7681}{\sin(23.15^\circ - 8^\circ)} = 2.94$$

$$\text{Strong shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.4553}{\sin(87.45^\circ - 8^\circ)} = 0.463$$

Discussion Note that the change in Mach number and pressure across the *strong shock* are much greater than the changes across the *weak shock*, as expected. For both the weak and strong oblique shock cases, $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ is subsonic. However, Ma_2 is *supersonic* across the weak oblique shock, but *subsonic* across the strong oblique shock.

Duct Flow with Heat Transfer and Negligible Friction (Rayleigh Flow)

17-99C The characteristic aspect of Rayleigh flow is **its involvement of heat transfer**. The main assumptions associated with Rayleigh flow are: the flow is **steady, one-dimensional, and frictionless** through a constant-area duct, and the fluid is an **ideal gas with constant specific heats**.

Discussion Of course, there is no such thing as frictionless flow. It is better to say that frictional effects are negligible compared to the heating effects.

17-100C The points on the Rayleigh line represent the **states that satisfy the conservation of mass, momentum, and energy equations as well as the property relations for a given state**. Therefore, for a given inlet state, the fluid cannot exist at any downstream state outside the Rayleigh line on a *T-s* diagram.

Discussion The *T-s* diagram is quite useful, since any downstream state must lie on the Rayleigh line.

17-101C In Rayleigh flow, **the effect of heat gain is to increase the entropy of the fluid, and the effect of heat loss is to decrease the entropy**.

Discussion You should recall from thermodynamics that the entropy of a system can be lowered by removing heat.

17-102C In Rayleigh flow, the **stagnation temperature T_0 always increases with heat transfer to the fluid**, but the temperature T decreases with heat transfer in the Mach number range of $0.845 < Ma < 1$ for air. Therefore, the **temperature in this case will decrease**.

Discussion This at first seems counterintuitive, but if heat were *not* added, the temperature would drop even *more* if the air were accelerated isentropically from $Ma = 0.92$ to 0.95 .

17-103C Heating the fluid **increases the flow velocity in subsonic Rayleigh flow, but decreases the flow velocity in supersonic Rayleigh flow**.

Discussion These results are not necessarily intuitive, but must be true in order to satisfy the conservation laws.

17-104C The flow is choked, and thus the flow at the duct exit **remains sonic**.

Discussion There is no mechanism for the flow to become supersonic in this case.

17-105 Fuel is burned in a tubular combustion chamber with compressed air. For a specified exit Mach number, the exit temperature and the rate of fuel consumption are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Combustion is complete, and it is treated as a heat addition process, with no change in the chemical composition of flow. **3** The increase in mass flow rate due to fuel injection is disregarded.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The inlet density and mass flow rate of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{380 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(450 \text{ K})} = 2.942 \text{ kg/m}^3$$

$$\dot{m}_{\text{air}} = \rho_1 A_{\text{c1}} V_1 = (2.942 \text{ kg/m}^3)[\pi(0.16 \text{ m})^2 / 4](55 \text{ m/s}) = 3.254 \text{ kg/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 450 \text{ K} + \frac{(55 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 451.5 \text{ K}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(450 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = 425.2 \text{ m/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{55 \text{ m/s}}{425.2 \text{ m/s}} = 0.1293$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34) (We used analytical functions):

$$\text{Ma}_1 = 0.1293: \quad T_1/T^* = 0.09201, \quad T_{01}/T^* = 0.07693, \quad V_1/V^* = 0.03923$$

$$\text{Ma}_2 = 0.8: \quad T_2/T^* = 1.0255, \quad T_{02}/T^* = 0.9639, \quad V_2/V^* = 0.8101$$

The exit temperature, stagnation temperature, and velocity are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1.0255}{0.09201} = 11.146 \rightarrow T_2 = 11.146 T_1 = 11.146(450 \text{ K}) = \mathbf{5016 \text{ K}}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{0.9639}{0.07693} = 12.530 \rightarrow T_{02} = 12.530 T_{01} = 12.530(451.5 \text{ K}) = 5658 \text{ K}$$

$$\frac{V_2}{V_1} = \frac{V_2/V^*}{V_1/V^*} = \frac{0.8101}{0.03923} = 20.650 \rightarrow V_2 = 20.650 V_1 = 20.650(55 \text{ m/s}) = 1136 \text{ m/s}$$

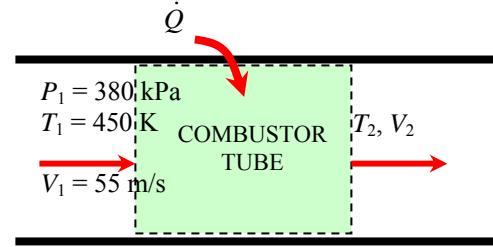

Then the mass flow rate of the fuel is determined to be

$$q = c_p(T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(5658 - 451.5) \text{ K} = 5232 \text{ kJ/kg}$$

$$\dot{Q} = \dot{m}_{\text{air}} q = (3.254 \text{ kg/s})(5232 \text{ kJ/kg}) = 17,024 \text{ kW}$$

$$\dot{m}_{\text{fuel}} = \frac{\dot{Q}}{HV} = \frac{17,024 \text{ kJ/s}}{39,000 \text{ kJ/kg}} = \mathbf{0.4365 \text{ kg/s}}$$

Discussion Note that both the temperature and velocity increase during this subsonic Rayleigh flow with heating, as expected. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-106 Air is heated in a duct during subsonic flow until it is choked. For specified pressure and velocity at the exit, the temperature, pressure, and velocity at the inlet are to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis Noting that sonic conditions exist at the exit, the exit temperature is

$$c_2 = V_2/\text{Ma}_2 = (620 \text{ m/s})/1 = 620 \text{ m/s}$$

$$c_2 = \sqrt{kRT_2} \rightarrow \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})T_2 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 620 \text{ m/s}$$

It gives $T_2 = 956.7 \text{ K}$. Then the exit stagnation temperature becomes

$$T_{02} = T_2 + \frac{V_2^2}{2c_p} = 956.7 \text{ K} + \frac{(620 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 1148 \text{ K}$$

The inlet stagnation temperature is, from the energy equation $q = c_p(T_{02} - T_{01})$,

$$T_{01} = T_{02} - \frac{q}{c_p} = 1148 \text{ K} - \frac{52 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 1096 \text{ K}$$

The maximum value of stagnation temperature T_0^* occurs at $\text{Ma} = 1$, and its value in this case is T_{02} since the flow is choked. Therefore, $T_0^* = T_{02} = 1148 \text{ K}$. Then the stagnation temperature ratio at the inlet, and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{01}}{T_0^*} = \frac{1096 \text{ K}}{1148 \text{ K}} = 0.9547 \quad \rightarrow \quad \text{Ma}_1 = 0.7792 \approx \mathbf{0.779}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.7792: \quad T_1/T^* = 1.022, \quad P_1/P^* = 1.297, \quad V_1/V^* = 0.7877$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad V_2/V^* = 1$$

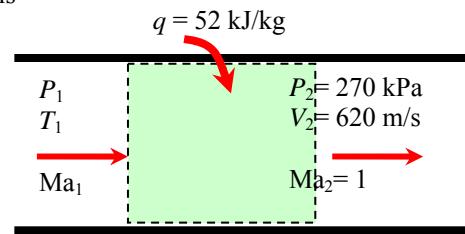

Then the inlet temperature, pressure, and velocity are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{1.017} \quad \rightarrow \quad T_1 = 1.022T_2 = 1.022(956.7 \text{ K}) = \mathbf{977.5 \text{ K}}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{1.319} \quad \rightarrow \quad P_1 = 1.319P_2 = 1.297(270 \text{ kPa}) = \mathbf{350.3 \text{ kPa}}$$

$$\frac{V_2}{V_1} = \frac{V_2/V^*}{V_1/V^*} = \frac{1}{0.7719} \quad \rightarrow \quad V_1 = 0.7877V_2 = 0.7877(620 \text{ m/s}) = \mathbf{488.4 \text{ m/s}}$$

Discussion Note that the temperature and pressure decreases with heating during this subsonic Rayleigh flow while velocity increases. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-107E Air flowing with a subsonic velocity in a round duct is accelerated by heating until the flow is choked at the exit. The rate of heat transfer and the pressure drop are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The flow is choked at the duct exit. **3** Mass flow rate remains constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 0.2400 \text{ Btu/lbm}\cdot\text{R}$, and $R = 0.06855 \text{ Btu/lbm}\cdot\text{R} = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$.

Analysis The inlet density and velocity of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{30 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(800 \text{ R})} = 0.1012 \text{ lbm/ft}^3$$

$$V_1 = \frac{\dot{m}_{air}}{\rho_1 A_{c1}} = \frac{5 \text{ lbm/s}}{(0.1012 \text{ lbm/ft}^3)[\pi(4/12 \text{ ft})^2 / 4]} = 565.9 \text{ ft/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 800 \text{ R} + \frac{(565.9 \text{ ft/s})^2}{2 \times 0.2400 \text{ Btu/lbm}\cdot\text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 826.7 \text{ R}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(800 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1386 \text{ ft/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{565.9 \text{ ft/s}}{1386 \text{ ft/s}} = 0.4082$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.4082: \quad T_1/T^* = 0.6310, \quad P_1/P^* = 1.946, \quad T_{01}/T_0^* = 0.5434$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature, pressure, and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.6310} \rightarrow T_2 = T_1/0.6310 = (800 \text{ R})/0.6310 = 1268 \text{ R}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{1.946} \rightarrow P_2 = P_1/2.272 = (30 \text{ psia})/1.946 = 15.4 \text{ psia}$$

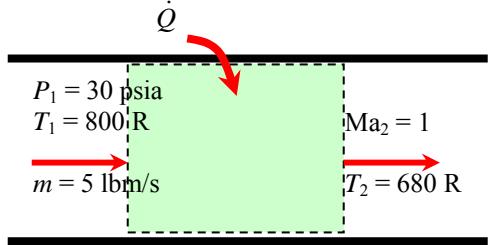

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{1}{0.5434} \rightarrow T_{02} = T_{01}/0.1743 = (826.7 \text{ R})/0.5434 = 1521 \text{ R}$$

Then the rate of heat transfer and the pressure drop become

$$\dot{Q} = \dot{m}_{air} c_p (T_{02} - T_{01}) = (5 \text{ lbm/s})(0.2400 \text{ Btu/lbm}\cdot\text{R})(1521 - 826.7) \text{ R} = \mathbf{834 \text{ Btu/s}}$$

$$\Delta P = P_1 - P_2 = 30 - 15.4 = \mathbf{14.6 \text{ psia}}$$

Discussion Note that the entropy of air increases during this heating process, as expected.

17-108 Air flowing with a subsonic velocity in a duct. The variation of entropy with temperature is to be investigated as the exit temperature varies from 600 K to 5000 K in increments of 200 K. The results are to be tabulated and plotted.

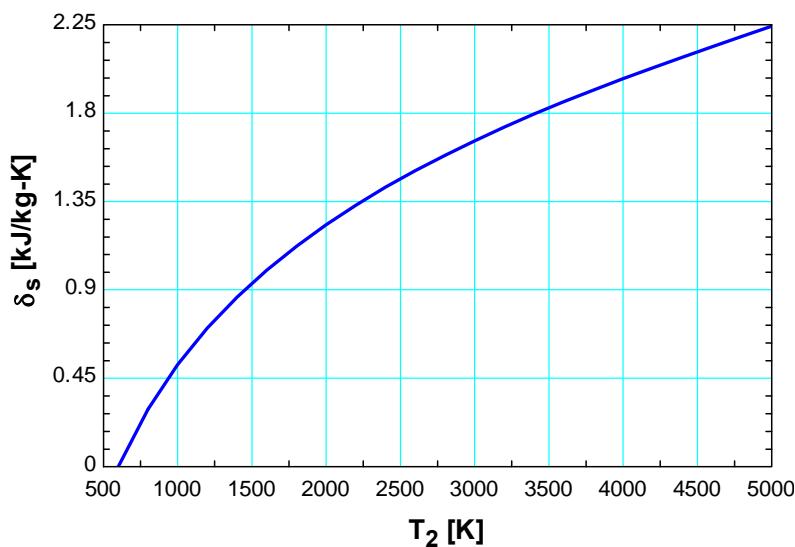

Analysis We solve this problem using EES making use of Rayleigh functions. The EES *Equations* window is printed below, along with the tabulated and plotted results.

Discussion Note that the entropy of air increases during this heating process, as expected.

17-109E Air flowing with a subsonic velocity in a square duct is accelerated by heating until the flow is choked at the exit. The rate of heat transfer and the entropy change are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The flow is choked at the duct exit. **3** Mass flow rate remains constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 0.2400 \text{ Btu/lbm}\cdot\text{R}$, and $R = 0.06855 \text{ Btu/lbm}\cdot\text{R} = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$.

Analysis The inlet density and mass flow rate of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{80 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(700 \text{ R})} = 0.3085 \text{ lbm}/\text{ft}^3$$

$$\dot{m}_{\text{air}} = \rho_1 A_{\text{cl}} V_1 = (0.3085 \text{ lbm}/\text{ft}^3)(6 \times 6/144 \text{ ft}^2)(260 \text{ ft/s}) = 20.06 \text{ lbm/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 700 \text{ R} + \frac{(260 \text{ ft/s})^2}{2 \times 0.2400 \text{ Btu/lbm}\cdot\text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 705.6 \text{ R}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(700 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1297 \text{ ft/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{260 \text{ ft/s}}{1297 \text{ ft/s}} = 0.2005$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.2005: \quad T_1/T^* = 0.2075, \quad P_1/P^* = 2.272, \quad T_{01}/T_0^* = 0.1743$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature, pressure, and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.2075} \rightarrow T_2 = T_1/0.2075 = (700 \text{ R})/0.2075 = 3374 \text{ R}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{2.272} \rightarrow P_2 = P_1/2.272 = (80 \text{ psia})/2.272 = 35.2 \text{ psia}$$

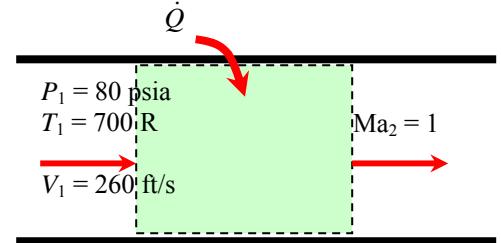

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{1}{0.1743} \rightarrow T_{02} = T_{01}/0.1743 = (705.6 \text{ R})/0.1743 = 4048 \text{ R}$$

Then the rate of heat transfer and entropy change become

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (20.06 \text{ lbm/s})(0.2400 \text{ Btu/lbm}\cdot\text{R})(4048 - 705.6) \text{ R} = \mathbf{16,090 \text{ Btu/s}}$$

$$\begin{aligned} \Delta s &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (0.2400 \text{ Btu/lbm}\cdot\text{R}) \ln \frac{3374 \text{ R}}{700 \text{ R}} - (0.06855 \text{ Btu/lbm}\cdot\text{R}) \ln \frac{35.2 \text{ psia}}{80 \text{ psia}} = \mathbf{0.434 \text{ Btu/lbm}\cdot\text{R}} \end{aligned}$$

Discussion Note that the entropy of air increases during this heating process, as expected.

17-110 Air enters the combustion chamber of a gas turbine at a subsonic velocity. For a specified rate of heat transfer, the Mach number at the exit and the loss in stagnation pressure to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The cross-sectional area of the combustion chamber is constant. **3** The increase in mass flow rate due to fuel injection is disregarded.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The inlet stagnation temperature and pressure are

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} Ma_1^2 \right) = (550 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right) = 554.4 \text{ K}$$

$$P_{01} = P_1 \left(1 + \frac{k-1}{2} Ma_1^2 \right)^{k/(k-1)} = (600 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right)^{1.4/0.4} = 617.0 \text{ kPa}$$

The exit stagnation temperature is determined from

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) \rightarrow 200 \text{ kJ/s} = (0.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(T_{02} - 554.4) \text{ K}$$

It gives

$$T_{02} = 1218 \text{ K.}$$

At $Ma_1 = 0.2$ we read from $T_{01}/T_0^* = 0.1736$ (Table A-34). Therefore,

$$T_0^* = \frac{T_{01}}{0.1736} = \frac{554.4 \text{ K}}{0.1736} = 3193.5 \text{ K}$$

Then the stagnation temperature ratio at the exit and the Mach number corresponding to it are (Table A-34)

$$\frac{T_{02}}{T_0^*} = \frac{1218 \text{ K}}{3193.5 \text{ K}} = 0.3814 \rightarrow Ma_2 = 0.3187 \approx \mathbf{0.319}$$

Also,

$$Ma_1 = 0.2 \rightarrow P_{01}/P_0^* = 1.2346$$

$$Ma_2 = 0.3187 \rightarrow P_{02}/P_0^* = 1.191$$

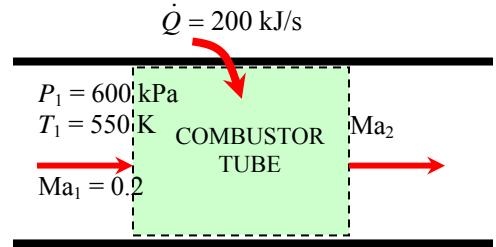

Then the stagnation pressure at the exit and the pressure drop become

$$\frac{P_{02}}{P_{01}} = \frac{P_{02}/P_0^*}{P_{01}/P_0^*} = \frac{1.191}{1.2346} = 0.9647 \rightarrow P_{02} = 0.9647 P_{01} = 0.9647(617 \text{ kPa}) = 595.2 \text{ kPa}$$

and

$$\Delta P_0 = P_{01} - P_{02} = 617.0 - 595.2 = \mathbf{21.8 \text{ kPa}}$$

Discussion This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-111 Air enters the combustion chamber of a gas turbine at a subsonic velocity. For a specified rate of heat transfer, the Mach number at the exit and the loss in stagnation pressure to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** The cross-sectional area of the combustion chamber is constant. **3** The increase in mass flow rate due to fuel injection is disregarded.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The inlet stagnation temperature and pressure are

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} Ma_1^2 \right) = (550 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right) = 554.4 \text{ K}$$

$$P_{01} = P_1 \left(1 + \frac{k-1}{2} Ma_1^2 \right)^{k/(k-1)} = (600 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right)^{1.4/0.4} = 617.0 \text{ kPa}$$

The exit stagnation temperature is determined from

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) \rightarrow 300 \text{ kJ/s} = (0.3 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(T_{02} - 554.4) \text{ K}$$

It gives

$$T_{02} = 1549 \text{ K}.$$

At $Ma_1 = 0.2$ we read from $T_{01}/T_0^* = 0.1736$ (Table A-34). Therefore,

$$T_0^* = \frac{T_{01}}{0.1736} = \frac{554.4 \text{ K}}{0.1736} = 3193.5 \text{ K}$$

Then the stagnation temperature ratio at the exit and the Mach number corresponding to it are (Table A-34)

$$\frac{T_{02}}{T_0^*} = \frac{1549 \text{ K}}{3193.5 \text{ K}} = 0.4850 \rightarrow Ma_2 = 0.3753 \approx \mathbf{0.375}$$

Also,

$$Ma_1 = 0.2 \rightarrow P_{01}/P_0^* = 1.2346$$

$$Ma_2 = 0.3753 \rightarrow P_{02}/P_0^* = 1.167$$

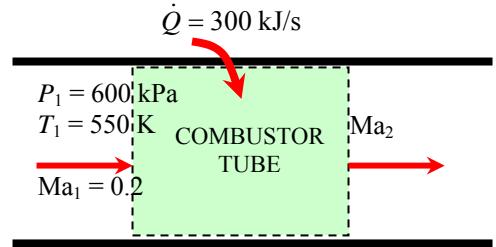

Then the stagnation pressure at the exit and the pressure drop become

$$\frac{P_{02}}{P_{01}} = \frac{P_{02}/P_0^*}{P_{01}/P_0^*} = \frac{1.167}{1.2346} = 0.9452 \rightarrow P_{02} = 0.9452 P_{01} = 0.9452(617 \text{ kPa}) = 583.3 \text{ kPa}$$

and

$$\Delta P_0 = P_{01} - P_{02} = 617.0 - 583.3 = \mathbf{33.7 \text{ kPa}}$$

Discussion This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-112 Fuel is burned in a rectangular duct with compressed air. For specified heat transfer, the exit temperature and Mach number are to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

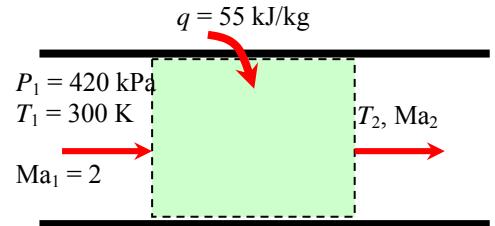

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation temperature and Mach number at the inlet are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = 347.2 \text{ m/s}$$

$$V_1 = Ma_1 c_1 = 2(347.2 \text{ m/s}) = 694.4 \text{ m/s}$$

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 300 \text{ K} + \frac{(694.4 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 539.9 \text{ K}$$

The exit stagnation temperature is, from the energy equation $q = c_p(T_{02} - T_{01})$,

$$T_{02} = T_{01} + \frac{q}{c_p} = 539.9 \text{ K} + \frac{55 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 594.6 \text{ K}$$

The maximum value of stagnation temperature T_0^* occurs at $Ma = 1$, and its value can be determined from Table A-34 or from the appropriate relation. At $Ma_1 = 2$ we read $T_{01}/T_0^* = 0.7934$. Therefore,

$$T_0^* = \frac{T_{01}}{0.7934} = \frac{539.9 \text{ K}}{0.7934} = 680.5 \text{ K}$$

The stagnation temperature ratio at the exit and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{02}}{T_0^*} = \frac{594.6 \text{ K}}{680.5 \text{ K}} = 0.8738 \quad \rightarrow \quad Ma_2 = 1.642 \approx \mathbf{1.64}$$

Also,

$$Ma_1 = 2 \quad \rightarrow \quad T_1/T^* = 0.5289$$

$$Ma_2 = 1.642 \quad \rightarrow \quad T_2/T^* = 0.6812$$

Then the exit temperature becomes

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{0.6812}{0.5289} = 1.288 \quad \rightarrow \quad T_2 = 1.288T_1 = 1.288(300 \text{ K}) = \mathbf{386 \text{ K}}$$

Discussion Note that the temperature increases during this supersonic Rayleigh flow with heating. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-113 Compressed air is cooled as it flows in a rectangular duct. For specified heat rejection, the exit temperature and Mach number are to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

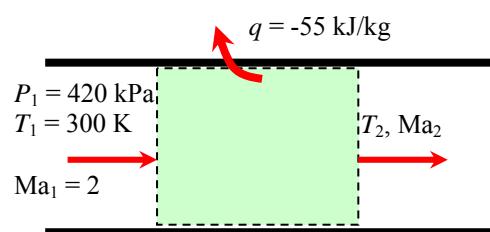

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation temperature and Mach number at the inlet are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = 347.2 \text{ m/s}$$

$$V_1 = Ma_1 c_1 = 2(347.2 \text{ m/s}) = 694.4 \text{ m/s}$$

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 300 \text{ K} + \frac{(694.4 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 539.9 \text{ K}$$

The exit stagnation temperature is, from the energy equation $q = c_p(T_{02} - T_{01})$,

$$T_{02} = T_{01} + \frac{q}{c_p} = 539.9 \text{ K} + \frac{-55 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 485.2 \text{ K}$$

The maximum value of stagnation temperature T_0^* occurs at $Ma = 1$, and its value can be determined from Table A-34 or from the appropriate relation. At $Ma_1 = 2$ we read $T_{01}/T_0^* = 0.7934$. Therefore,

$$T_0^* = \frac{T_{01}}{0.7934} = \frac{539.9 \text{ K}}{0.7934} = 680.5 \text{ K}$$

The stagnation temperature ratio at the exit and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{02}}{T_0^*} = \frac{485.2 \text{ K}}{680.5 \text{ K}} = 0.7130 \quad \rightarrow \quad Ma_2 = 2.479 \cong \mathbf{2.48}$$

Also,

$$Ma_1 = 2 \quad \rightarrow \quad T_1/T^* = 0.5289$$

$$Ma_2 = 2.479 \quad \rightarrow \quad T_2/T^* = 0.3838$$

Then the exit temperature becomes

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{0.3838}{0.5289} = 0.7257 \quad \rightarrow \quad T_2 = 0.7257 T_1 = 0.7257(300 \text{ K}) = \mathbf{218 \text{ K}}$$

Discussion Note that the temperature decreases and Mach number increases during this supersonic Rayleigh flow with cooling. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-114 Argon flowing at subsonic velocity in a constant-diameter duct is accelerated by heating. The highest rate of heat transfer without reducing the mass flow rate is to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Mass flow rate remains constant.

Properties We take the properties of argon to be $k = 1.667$, $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$.

Analysis Heat transfer stops when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. The inlet stagnation temperature is

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (400 \text{ K}) \left(1 + \frac{1.667-1}{2} 0.2^2 \right) = 405.3 \text{ K}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \text{ (since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.667+1)0.2^2 [2 + (1.667-1)0.2^2]}{(1+1.667 \times 0.2^2)^2} = 0.1900$$

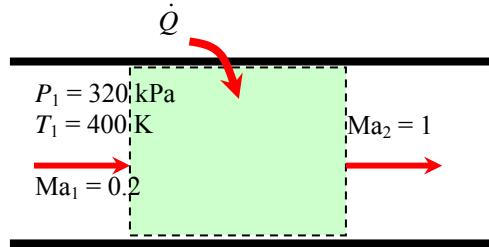

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.1900} \rightarrow T_{02} = T_{01}/0.1900 = (405.3 \text{ K})/0.1900 = 2133 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (1.2 \text{ kg/s})(0.5203 \text{ kJ/kg}\cdot\text{K})(2133 - 400) \text{ K} = \mathbf{1080 \text{ kW}}$$

Discussion It can also be shown that $T_2 = 1600 \text{ K}$, which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. Also, in the solution of this problem, we cannot use the values of Table A-34 since they are based on $k = 1.4$.

17-115 Air flowing at a supersonic velocity in a duct is decelerated by heating. The highest temperature air can be heated by heat addition and the rate of heat transfer are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Mass flow rate remains constant.

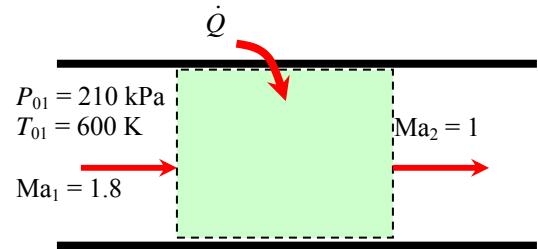

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis Heat transfer will stop when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. Knowing stagnation properties, the static properties are determined to be

$$T_1 = T_{01} \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-1} = (600 \text{ K}) \left(1 + \frac{1.4-1}{2} 1.8^2 \right)^{-1} = 364.1 \text{ K}$$

$$P_1 = P_{01} \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-k/(k-1)} = (210 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 1.8^2 \right)^{-1.4/0.4} = 36.55 \text{ kPa}$$

$$\rho_1 = \frac{P_1}{RT_1} = \frac{36.55 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(364.1 \text{ K})} = 0.3498 \text{ kg/m}^3$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(364.1 \text{ K}) \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 382.5 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 1.8(382.5 \text{ m/s}) = 688.5 \text{ m/s}$$

$$\dot{m}_{air} = \rho_1 A_{c1} V_1 = (0.3498 \text{ kg/m}^3) [\pi(0.10 \text{ m})^2 / 4] (688.5 \text{ m/s}) = 1.891 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1.8: \quad T_1/T^* = 0.6089, \quad T_{01}/T_0^* = 0.8363$$

$$\text{Ma}_2 = 1: T_2/T^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.6089} \quad \rightarrow \quad T_2 = T_1 / 0.6089 = (364.1 \text{ K}) / 0.6089 = \mathbf{598 \text{ K}}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.8363} \quad \rightarrow \quad T_{02} = T_{01} / 0.8363 = (600 \text{ K}) / 0.8363 = 717.4 \text{ K} \cong \mathbf{717 \text{ K}}$$

Finally, the rate of heat transfer is

$$\dot{Q} = \dot{m}_{air} c_p (T_{02} - T_{01}) = (1.891 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(717.4 - 600) \text{ K} = \mathbf{223 \text{ kW}}$$

Discussion Note that this is the highest temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature will cause the mass flow rate to decrease. Also, once the sonic conditions are reached, the thermodynamic temperature can be increased further by cooling the fluid and reducing the velocity (see the T - s diagram for Rayleigh flow).

Steam Nozzles

17-116C The delay in the condensation of the steam is called supersaturation. It occurs in high-speed flows where there isn't sufficient time for the necessary heat transfer and the formation of liquid droplets.

17-117 Steam enters a converging nozzle with a low velocity. The exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

Assumptions 1 Flow through the nozzle is steady and one-dimensional. 2 The nozzle is adiabatic.

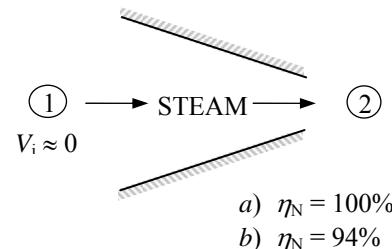

Analysis (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\begin{aligned} P_1 &= P_{01} = 4 \text{ MPa} \\ T_1 &= T_{01} = 400^\circ\text{C} \end{aligned} \quad \left. \begin{aligned} h_1 &= h_{01} = 3214.5 \text{ kJ/kg} \\ s_1 &= s_{2s} = 6.7714 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\}$$

At the exit,

$$\begin{aligned} P_2 &= 2.5 \text{ MPa} \\ s_2 &= 6.7714 \text{ kJ/kg} \cdot \text{K} \end{aligned} \quad \left. \begin{aligned} h_2 &= 3083.4 \text{ kJ/kg} \\ v_2 &= 0.1058 \text{ m}^3/\text{kg} \end{aligned} \right\}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3214.5 - 3083.4) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 512.0 \text{ m/s}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.1058 \text{ m}^3/\text{kg}} (32 \times 10^{-4} \text{ m}^2)(512.0 \text{ m/s}) = 15.49 \text{ kg/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left(\frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 6.7714 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (2.0 and 3.0 MPa) are determined to be 0.1257 and 0.09183 m^3/kg . Substituting,

$$c_2 = \sqrt{\frac{(3000 - 2000) \text{ kPa}}{\left(\frac{1}{0.09183} - \frac{1}{0.1257} \right) \text{ kg/m}^3} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa.m}^3} \right)} = 583.7 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{512.0 \text{ m/s}}{583.7 \text{ m/s}} = 0.877$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\begin{aligned} P_1 &= P_{01} = 4 \text{ MPa} \\ T_1 &= T_{01} = 400^\circ\text{C} \end{aligned} \quad \left. \begin{aligned} h_1 &= h_{01} = 3214.5 \text{ kJ/kg} \\ s_1 &= s_{2s} = 6.7714 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\}$$

At state 2s,

$$\left. \begin{array}{l} P_{2s} = 2.5 \text{ MPa} \\ s_{2s} = 6.7714 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 3083.4 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.94 = \frac{3214.5 - h_2}{3214.5 - 3288.7} \longrightarrow h_2 = 3091.3 \text{ kJ/kg}$$

Therefore,

$$\left. \begin{array}{l} P_2 = 2.5 \text{ MPa} \\ h_2 = 3091.3 \text{ kJ/kg} \end{array} \right\} \nu_2 = 0.1065 \text{ m}^3/\text{kg}$$

$$s_2 = 6.7844 \text{ kJ/kg} \cdot \text{K}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_l + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_l + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_l - h_2)} = \sqrt{2(3214.5 - 3091.3) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 496.4 \text{ m/s}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{\nu_2} A_2 V_2 = \frac{1}{0.1065 \text{ m}^3/\text{kg}} (32 \times 10^{-4} \text{ m}^2)(496.4 \text{ m/s}) = 14.92 \text{ kg/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \approx \left(\frac{\Delta P}{\Delta(1/\nu)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 6.7844 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (2.0 and 3.0 MPa) are determined to be 0.1266 and 0.09246 m^3/kg . Substituting,

$$c_2 = \sqrt{\left(\frac{(3000 - 2000) \text{ kPa}}{\left(\frac{1}{0.09246} - \frac{1}{0.1266} \right) \text{ kg/m}^3} \right) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 585.7 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{496.4 \text{ m/s}}{585.7 \text{ m/s}} = 0.848$$

17-118E Steam enters a converging nozzle with a low velocity. The exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

Assumptions 1 Flow through the nozzle is steady and one-dimensional. 2 The nozzle is adiabatic.

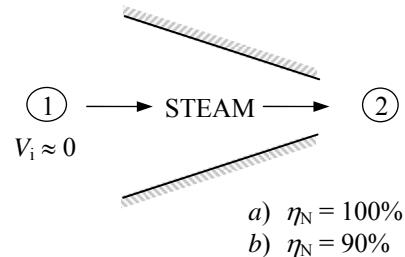

Analysis (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{array}{l} P_1 = P_{01} = 450 \text{ psia} \\ T_1 = T_{01} = 900^\circ\text{F} \end{array} \right\} \left. \begin{array}{l} h_1 = h_{01} = 1468.6 \text{ Btu/lbm} \\ s_1 = s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{array} \right.$$

At the exit,

$$\left. \begin{array}{l} P_2 = 275 \text{ psia} \\ s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{array} \right\} \left. \begin{array}{l} h_2 = 1400.5 \text{ Btu/lbm} \\ v_2 = 2.5732 \text{ ft}^3/\text{lbm} \end{array} \right.$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(1468.6 - 1400.5) \text{ Btu/lbm} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1847 \text{ ft/s}$$

Then,

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{2.5732 \text{ ft}^3/\text{lbm}} (3.75/144 \text{ ft}^2)(1847 \text{ ft/s}) = 18.7 \text{ lbm/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left(\frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 1.7117 \text{ Btu/lbm} \cdot \text{R}$ and at pressures just below and just above the specified pressure (250 and 300 psia) are determined to be 2.7709 and 2.4048 ft^3/lbm . Substituting,

$$c_2 = \sqrt{ \left(\frac{(300 - 250) \text{ psia}}{\left(\frac{1}{2.4048} - \frac{1}{2.7709} \right) \text{ lbm/ft}^3} \right) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \left(\frac{1 \text{ Btu}}{5.4039 \text{ ft}^3 \cdot \text{psia}} \right) } = 2053 \text{ ft/s}$$

Then the exit Mach number becomes

$$Ma_2 = \frac{V_2}{c_2} = \frac{1847 \text{ ft/s}}{2053 \text{ ft/s}} = 0.900$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{array}{l} P_1 = P_{01} = 450 \text{ psia} \\ T_1 = T_{01} = 900^\circ\text{F} \end{array} \right\} \left. \begin{array}{l} h_1 = h_{01} = 1468.6 \text{ Btu/lbm} \\ s_1 = s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{array} \right.$$

At state 2s,

$$\left. \begin{array}{l} P_{2s} = 275 \text{ psia} \\ s_{2s} = 1.7117 \text{ Btu/lbm} \cdot R \end{array} \right\} h_{2s} = 1400.5 \text{ Btu/lbm}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.90 = \frac{1468.6 - h_2}{1468.6 - 1400.5} \longrightarrow h_2 = 1407.3 \text{ Btu/lbm}$$

Therefore,

$$\left. \begin{array}{l} P_2 = 275 \text{ psia} \\ h_2 = 1407.3 \text{ Btu/lbm} \end{array} \right\} \nu_2 = 2.6034 \text{ ft}^3/\text{lbm}$$

$$s_2 = 1.7173 \text{ Btu/lbm} \cdot R$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_l + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_l + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_l - h_2)} = \sqrt{2(1468.6 - 1407.3) \text{ Btu/lbm} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1752 \text{ ft/s}$$

Then,

$$\dot{m} = \frac{1}{\nu_2} A_2 V_2 = \frac{1}{2.6034 \text{ ft}^3/\text{lbm}} (3.75/144 \text{ ft}^2)(1752 \text{ ft/s}) = 17.53 \text{ lbm/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \approx \left(\frac{\Delta P}{\Delta(1/\nu)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 1.7173 \text{ Btu/lbm} \cdot R$ and at pressures just below and just above the specified pressure (250 and 300 psia) are determined to be 2.8036 and 2.4329 ft^3/lbm . Substituting,

$$c_2 = \sqrt{\left(\frac{(300 - 250) \text{ psia}}{\left(\frac{1}{2.4329} - \frac{1}{2.8036} \right) \text{ lbm/ft}^3} \right) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \left(\frac{1 \text{ Btu}}{5.4039 \text{ ft}^3 \cdot \text{psia}} \right)} = 2065 \text{ ft/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1752 \text{ ft/s}}{2065 \text{ ft/s}} = 0.849$$

17-119 Steam enters a converging-diverging nozzle with a low velocity. The exit area and the exit Mach number are to be determined.

Assumptions Flow through the nozzle is steady, one-dimensional, and isentropic.

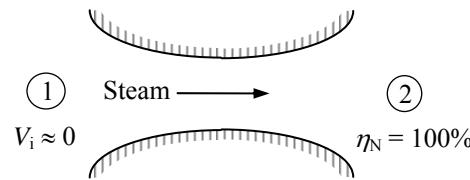

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\begin{aligned} P_1 &= P_{01} = 1 \text{ MPa} & h_1 = h_{01} &= 3479.1 \text{ kJ/kg} \\ T_1 &= T_{01} = 500^\circ\text{C} & s_1 &= s_{2s} = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At the exit,

$$\begin{aligned} P_2 &= 0.2 \text{ MPa} & h_2 &= 3000.0 \text{ kJ/kg} \\ s_2 &= 7.7642 \text{ kJ/kg} \cdot \text{K} & v_2 &= 1.2325 \text{ m}^3/\text{kg} \end{aligned}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3479.1 - 3000.0) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 978.9 \text{ m/s}$$

The exit area is determined from

$$A_2 = \frac{\dot{m}v_2}{V_2} = \frac{(2.5 \text{ kg/s})(1.2325 \text{ m}^3/\text{kg})}{(978.9 \text{ m/s})} = 31.5 \times 10^{-4} \text{ m}^2 = 31.5 \text{ cm}^2$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \approx \left(\frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (0.1 and 0.3 MPa) are determined to be 2.0935 and 0.9024 m^3/kg . Substituting,

$$c_2 = \sqrt{\left(\frac{1}{0.9024} - \frac{1}{2.0935} \right) \text{kg/m}^3 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 563.2 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{978.9 \text{ m/s}}{563.2 \text{ m/s}} = 1.738$$

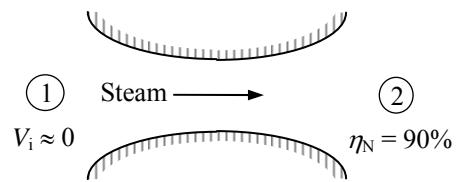

17-120 Steam enters a converging-diverging nozzle with a low velocity. The exit area and the exit Mach number are to be determined.

Assumptions Flow through the nozzle is steady and one-dimensional.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

$$\text{At the inlet, } \begin{cases} P_1 = P_{01} = 1 \text{ MPa} \\ T_1 = T_{01} = 500^\circ\text{C} \end{cases} \quad \begin{cases} h_1 = h_{01} = 3479.1 \text{ kJ/kg} \\ s_1 = s_{2s} = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

$$\text{At state } 2s, \begin{cases} P_2 = 0.2 \text{ MPa} \\ s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{cases} \quad \begin{cases} h_{2s} = 3000.0 \text{ kJ/kg} \end{cases}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.90 = \frac{3479.1 - h_2}{3479.1 - 3000.0} \longrightarrow h_2 = 3047.9 \text{ kJ/kg}$$

Therefore,

$$\begin{cases} P_2 = 0.2 \text{ MPa} \\ h_2 = 3047.9 \text{ kJ/kg} \end{cases} \quad \begin{cases} v_2 = 1.2882 \text{ m}^3/\text{kg} \\ s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{cases}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3479.1 - 3047.9) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 928.7 \text{ m/s}$$

The exit area is determined from

$$A_2 = \frac{\dot{m}v_2}{V_2} = \frac{(2.5 \text{ kg/s})(1.2882 \text{ m}^3/\text{kg})}{928.7 \text{ m/s}} = 34.7 \times 10^{-4} \text{ m}^2 = \mathbf{34.7 \text{ cm}^2}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \approx \left(\frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (0.1 and 0.3 MPa) are determined to be 2.1903 and 0.9425 m^3/kg . Substituting,

$$c_2 = \sqrt{\left(\frac{1}{0.9425} - \frac{1}{2.1903} \right) \text{kg/m}^3 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 575.2 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{928.7 \text{ m/s}}{575.2 \text{ m/s}} = \mathbf{1.61}$$

Review Problems

17-121 A leak develops in an automobile tire as a result of an accident. The initial mass flow rate of air through the leak is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow of air through the hole is isentropic.

Properties The gas constant of air is $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$. The specific heat ratio of air at room temperature is $k = 1.4$ (Table A-2a).

Analysis The absolute pressure in the tire is

$$P = P_{\text{gage}} + P_{\text{atm}} = 220 + 94 = 314 \text{ kPa}$$

The critical pressure is, from Table 17-2,

$$P^* = 0.5283P_0 = (0.5283)(314 \text{ kPa}) = 166 \text{ kPa} > 94 \text{ kPa}$$

Therefore, the flow is choked, and the velocity at the exit of the hole is the sonic speed. Then the flow properties at the exit becomes

$$\rho_0 = \frac{P_0}{RT_0} = \frac{314 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(298 \text{ K})} = 3.671 \text{ kg/m}^3$$

$$\rho^* = \rho_0 \left(\frac{2}{k+1} \right)^{1/(k-1)} = (3.671 \text{ kg/m}^3) \left(\frac{2}{1.4+1} \right)^{1/(1.4-1)} = 2.327 \text{ kg/m}^3$$

$$T^* = \frac{2}{k+1} T_0 = \frac{2}{1.4+1} (298 \text{ K}) = 248.3 \text{ K}$$

$$V = c = \sqrt{kRT^*} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) (248.3 \text{ K})} = 315.9 \text{ m/s}$$

Then the initial mass flow rate through the hole becomes

$$\dot{m} = \rho A V = (2.327 \text{ kg/m}^3)[\pi(0.004 \text{ m})^2/4](315.9 \text{ m/s}) = 0.00924 \text{ kg/s} = \mathbf{0.554 \text{ kg/min}}$$

Discussion The mass flow rate will decrease with time as the pressure inside the tire drops.

17-122 The thrust developed by the engine of a Boeing 777 is about 380 kN. The mass flow rate of air through the nozzle is to be determined.

Assumptions 1 Air is an ideal gas with constant specific properties. **2** Flow of combustion gases through the nozzle is isentropic. **3** Choked flow conditions exist at the nozzle exit. **4** The velocity of gases at the nozzle inlet is negligible.

Properties The gas constant of air is $R = 0.287 \text{ kPa.m}^3/\text{kg.K}$ (Table A-1), and it can also be used for combustion gases. The specific heat ratio of combustion gases is $k = 1.33$ (Table 17-2).

Analysis The velocity at the nozzle exit is the sonic velocity, which is determined to be

$$V = c = \sqrt{kRT} = \sqrt{(1.33)(0.287 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) (265 \text{ K})} = 318.0 \text{ m/s}$$

Noting that thrust F is related to velocity by $F = \dot{m}V$, the mass flow rate of combustion gases is determined to be

$$\dot{m} = \frac{F}{V} = \frac{380,000 \text{ N}}{318.0 \text{ m/s}} \left(\frac{1 \text{ kg.m/s}^2}{1 \text{ N}} \right) = 1194.8 \text{ kg/s}$$

Discussion The combustion gases are mostly nitrogen (due to the 78% of N_2 in air), and thus they can be treated as air with a good degree of approximation.

17-123 A stationary temperature probe is inserted into an air duct reads 50°C. The actual temperature of air is to be determined.

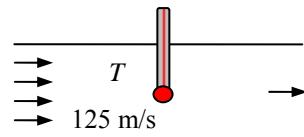

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. **2** The stagnation process is isentropic.

Properties The specific heat of air at room temperature is $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis The air that strikes the probe will be brought to a complete stop, and thus it will undergo a stagnation process. The thermometer will sense the temperature of this stagnated air, which is the stagnation temperature. The actual air temperature is determined from

$$T = T_0 - \frac{V^2}{2c_p} = 50^\circ\text{C} - \frac{(125 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 42.2^\circ\text{C}$$

Discussion Temperature rise due to stagnation is very significant in high-speed flows, and should always be considered when compressibility effects are not negligible.

17-124 Nitrogen flows through a heat exchanger. The stagnation pressure and temperature of the nitrogen at the inlet and the exit states are to be determined.

Assumptions 1 Nitrogen is an ideal gas with constant specific properties. **2** Flow of nitrogen through the heat exchanger is isentropic.

Properties The properties of nitrogen are $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The stagnation temperature and pressure of nitrogen at the inlet and the exit states are determined from

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 10^\circ\text{C} + \frac{(100 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot\text{°C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{14.8^\circ\text{C}}$$

$$P_{01} = P_1 \left(\frac{T_{01}}{T_1} \right)^{k/(k-1)} = (150 \text{ kPa}) \left(\frac{288.0 \text{ K}}{283.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{159.1 \text{ kPa}}$$

From the energy balance relation $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ with $w = 0$

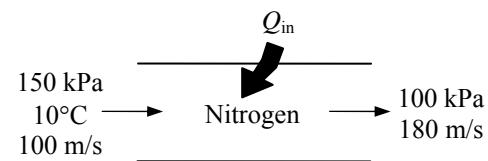

$$\begin{aligned} q_{\text{in}} &= c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2} + \Delta p e^{\phi_0} \\ 125 \text{ kJ/kg} &= (1.039 \text{ kJ/kg}\cdot\text{°C})(T_2 - 10^\circ\text{C}) + \frac{(180 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ T_2 &= 119.5^\circ\text{C} \end{aligned}$$

and

$$T_{02} = T_2 + \frac{V_2^2}{2c_p} = 119.5^\circ\text{C} + \frac{(180 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot\text{°C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{135.1^\circ\text{C}}$$

$$P_{02} = P_2 \left(\frac{T_{02}}{T_2} \right)^{k/(k-1)} = (100 \text{ kPa}) \left(\frac{408.3 \text{ K}}{392.7 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{114.6 \text{ kPa}}$$

Discussion Note that the stagnation temperature and pressure can be very different than their thermodynamic counterparts when dealing with compressible flow.

17-125 An expression for the speed of sound based on van der Waals equation of state is to be derived. Using this relation, the speed of sound in carbon dioxide is to be determined and compared to that obtained by ideal gas behavior.

Properties The properties of CO₂ are $R = 0.1889 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.279$ at $T = 50^\circ\text{C} = 323.2 \text{ K}$ (Table A-2b).

Analysis Van der Waals equation of state can be expressed as

$$P = \frac{RT}{v-b} - \frac{a}{v^2}$$

Differentiating,

$$\left(\frac{\partial P}{\partial v}\right)_T = -\frac{RT}{(v-b)^2} + \frac{2a}{v^3}$$

Noting that $\rho = 1/v \longrightarrow d\rho = -dv/v^2$, the speed of sound relation becomes

$$c^2 = k\left(\frac{\partial P}{\partial v}\right)_T = -v^2 k\left(\frac{\partial P}{\partial v}\right)_T$$

Substituting,

$$c^2 = \frac{v^2 kRT}{(v-b)^2} - \frac{2ak}{v}$$

Using the molar mass of CO₂ ($M = 44 \text{ kg/kmol}$), the constant a and b can be expressed per unit mass as

$$a = 0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2 \quad \text{and} \quad b = 9.705 \times 10^{-4} \text{ m}^3/\text{kg}$$

The specific volume of CO₂ is determined to be

$$200 \text{ kPa} = \frac{(0.1889 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(323.2 \text{ K})}{v - 0.0009705 \text{ m}^3/\text{kg}} - \frac{2 \times 0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2}{v^2} \rightarrow v = 0.3031 \text{ m}^3/\text{kg}$$

Substituting,

$$c = \left(\frac{\frac{(0.3031 \text{ m}^3/\text{kg})^2 (1.279)(0.1889 \text{ kJ/kg}\cdot\text{K})(323.2 \text{ K})}{(0.3031 - 0.0009705 \text{ m}^3/\text{kg})^2} \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}}{-\frac{2(0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^3)(1.279)}{(0.3031 \text{ m}^3/\text{kg})^2} \frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa}\cdot\text{m}^3/\text{kg}}} \right)^{1/2} = 277.5 \text{ m/s}$$

If we treat CO₂ as an ideal gas, the speed of sound becomes

$$c = \sqrt{kRT} = \sqrt{(1.279)(0.1889 \text{ kJ/kg}\cdot\text{K})(323.2 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 279.4 \text{ m/s}$$

Discussion Note that the ideal gas relation is the simplest equation of state, and it is very accurate for most gases encountered in practice. At high pressures and/or low temperatures, however, the gases deviate from ideal gas behavior, and it becomes necessary to use more complicated equations of state.

17-126 The equivalent relation for the speed of sound is to be verified using thermodynamic relations.

Analysis The two relations are $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s$ and $c^2 = k\left(\frac{\partial P}{\partial \rho}\right)_T$

From $r = 1/\nu \longrightarrow dr = -d\nu/\nu^2$. Thus,

$$c^2 = \left(\frac{\partial P}{\partial r}\right)_s = -\nu^2 \left(\frac{\partial P}{\partial \nu}\right)_s = -\nu^2 \left(\frac{\partial P}{\partial T} \frac{\partial T}{\partial \nu}\right)_s = -\nu^2 \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial T}{\partial \nu}\right)_s$$

From the cyclic rule,

$$(P, T, s) : \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial T}{\partial s}\right)_P \left(\frac{\partial s}{\partial P}\right)_T = -1 \longrightarrow \left(\frac{\partial P}{\partial T}\right)_s = -\left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial P}{\partial s}\right)_T$$

$$(T, \nu, s) : \left(\frac{\partial T}{\partial \nu}\right)_s \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial s}{\partial T}\right)_\nu = -1 \longrightarrow \left(\frac{\partial T}{\partial \nu}\right)_s = -\left(\frac{\partial s}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial s}\right)_\nu$$

Substituting,

$$c^2 = -\nu^2 \left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial P}{\partial s}\right)_T \left(\frac{\partial s}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial s}\right)_\nu = -\nu^2 \left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial T}{\partial s}\right)_\nu \left(\frac{\partial P}{\partial s}\right)_T$$

Recall that

$$\frac{c_p}{T} = \left(\frac{\partial s}{\partial T}\right)_P \quad \text{and} \quad \frac{c_v}{T} = \left(\frac{\partial s}{\partial T}\right)_\nu$$

Substituting,

$$c^2 = -\nu^2 \left(\frac{c_p}{T}\right) \left(\frac{T}{c_v}\right) \left(\frac{\partial P}{\partial \nu}\right)_T = -\nu^2 k \left(\frac{\partial P}{\partial \nu}\right)_T$$

Replacing $-d\nu/\nu^2$ by $d\rho$,

$$c^2 = k \left(\frac{\partial P}{\partial \rho}\right)_T$$

Discussion Note that the differential thermodynamic property relations are very useful in the derivation of other property relations in differential form.

17-127 For ideal gases undergoing isentropic flows, expressions for P/P^* , T/T^* , and ρ/ρ^* as functions of k and Ma are to be obtained.

Analysis Equations 17-18 and 17-21 are given to be

$$\frac{T_0}{T} = \frac{2 + (k - 1)Ma^2}{2}$$

and

$$\frac{T^*}{T_0} = \frac{2}{k + 1}$$

Multiplying the two,

$$\left(\frac{T_0}{T} \frac{T^*}{T_0} \right) = \left(\frac{2 + (k - 1)Ma^2}{2} \right) \left(\frac{2}{k + 1} \right)$$

Simplifying and inverting,

$$\frac{T}{T^*} = \frac{k + 1}{2 + (k - 1)Ma^2} \quad (1)$$

From

$$\frac{P}{P^*} = \left(\frac{T}{T^*} \right)^{k/(k-1)} \longrightarrow \frac{P}{P^*} = \left(\frac{k + 1}{2 + (k - 1)Ma^2} \right)^{k/(k-1)} \quad (2)$$

From

$$\frac{\rho}{\rho^*} = \left(\frac{P}{P^*} \right)^{k/(k-1)} \longrightarrow \frac{\rho}{\rho^*} = \left(\frac{k + 1}{2 + (k - 1)Ma^2} \right)^{k/(k-1)} \quad (3)$$

Discussion Note that some very useful relations can be obtained by very simple manipulations.

17-128 It is to be verified that for the steady flow of ideal gases $dT_0/T = dA/A + (1-Ma^2) dV/V$. The effect of heating and area changes on the velocity of an ideal gas in steady flow for subsonic flow and supersonic flow are to be explained.

Analysis We start with the relation $\frac{V^2}{2} = c_p(T_0 - T)$, (1)

$$\text{Differentiating, } V dV = c_p(dT_0 - dT) \quad (2)$$

$$\text{We also have } \frac{d\rho}{\rho} + \frac{dA}{A} + \frac{dV}{V} = 0 \quad (3)$$

$$\text{and } \frac{dP}{\rho} + V dV = 0 \quad (4)$$

$$\text{Differentiating the ideal gas relation } P = \rho RT, \quad \frac{dP}{P} = \frac{d\rho}{\rho} + \frac{dT}{T} = 0 \quad (5)$$

$$\text{From the speed of sound relation, } c^2 = kRT = (k-1)c_p T = kP/\rho \quad (6)$$

$$\text{Combining Eqs. (3) and (5), } \frac{dP}{P} - \frac{dT}{T} + \frac{dA}{A} + \frac{dV}{V} = 0 \quad (7)$$

$$\text{Combining Eqs. (4) and (6), } \frac{dP}{\rho} = \frac{dP}{kP/c^2} = -V dV$$

$$\text{or, } \frac{dP}{P} = -\frac{k}{c^2} V dV = -k \frac{V^2}{c^2} \frac{dV}{V} = -k Ma^2 \frac{dV}{V} \quad (8)$$

Combining Eqs. (2) and (6),

$$dT = dT_0 - V \frac{dV}{c_p}$$

$$\text{or, } \frac{dT}{T} = \frac{dT_0}{T} - \frac{V^2}{c_p T} \frac{dV}{V} = \frac{dT}{T} = \frac{dT_0}{T} - \frac{V^2}{c^2/(k-1)} \frac{dV}{V} = \frac{dT_0}{T} - (k-1)Ma^2 \frac{dV}{V} \quad (9)$$

Combining Eqs. (7), (8), and (9),

$$-(k-1)Ma^2 \frac{dV}{V} - \frac{dT_0}{T} + (k-1)Ma^2 \frac{dV}{V} + \frac{dA}{A} + \frac{dV}{V} = 0$$

$$\text{or, } \frac{dT_0}{T} = \frac{dA}{A} + [-kMa^2 + (k-1)Ma^2 + 1] \frac{dV}{V}$$

$$\text{Thus, } \frac{dT_0}{T} = \frac{dA}{A} + (1 - Ma^2) \frac{dV}{V} \quad (10)$$

Differentiating the steady-flow energy equation $q = h_{02} - h_{01} = c_p(T_{02} - T_{01})$

$$\delta q = c_p dT_0 \quad (11)$$

Eq. (11) relates the stagnation temperature change dT_0 to the net heat transferred to the fluid. Eq. (10) relates the velocity changes to area changes dA , and the stagnation temperature change dT_0 or the heat transferred.

(a) When $Ma < 1$ (subsonic flow), the fluid will accelerate if the duct converges ($dA < 0$) or the fluid is heated ($dT_0 > 0$ or $\delta q > 0$). The fluid will decelerate if the duct converges ($dA < 0$) or the fluid is cooled ($dT_0 < 0$ or $\delta q < 0$).

(b) When $Ma > 1$ (supersonic flow), the fluid will accelerate if the duct diverges ($dA > 0$) or the fluid is cooled ($dT_0 < 0$ or $\delta q < 0$). The fluid will decelerate if the duct converges ($dA < 0$) or the fluid is heated ($dT_0 > 0$ or $\delta q > 0$).

17-129 A pitot tube measures the difference between the static and stagnation pressures for a subsonic airplane. The speed of the airplane and the flight Mach number are to be determined.

Assumptions 1 Air is an ideal gas with constant specific heat ratio. 2 The stagnation process is isentropic.

Properties The properties of air are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The stagnation pressure of air at the specified conditions is

$$P_0 = P + \Delta P = 30.8 + 20 = 50.8 \text{ kPa}$$

Then,

$$\frac{P_0}{P} = \left(1 + \frac{(k-1)\text{Ma}^2}{2}\right)^{k/k-1} \longrightarrow \frac{50.8}{30.8} = \left(1 + \frac{(1.4-1)\text{Ma}^2}{2}\right)^{1.4/0.4}$$

It yields

$$\text{Ma} = \mathbf{0.877}$$

The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(240 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right) = 310.5 \text{ m/s}$$

Thus, $V = \text{Ma} \times c = (0.877)(310.5 \text{ m/s}) = \mathbf{272 \text{ m/s}}$

Discussion Note that the flow velocity can be measured in a simple and accurate way by simply measuring pressure.

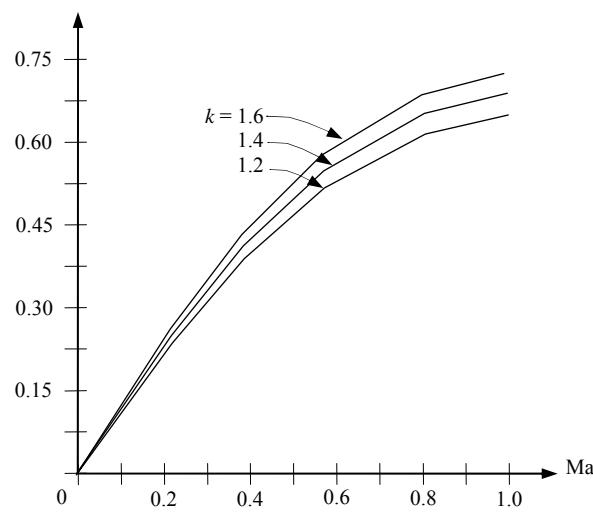

17-130 The mass flow parameter $\dot{m}\sqrt{RT_0} / (AP_0)$ versus the Mach number for $k = 1.2$, 1.4 , and 1.6 in the range of $0 \leq \text{Ma} \leq 1$ is to be plotted.

Analysis The mass flow rate parameter $(\dot{m}\sqrt{RT_0}) / P_0 A$ can be expressed as

$$\frac{\dot{m}\sqrt{RT_0}}{P_0 A} = \text{Ma} \sqrt{k} \left(\frac{2}{2 + (k-1)\text{Ma}^2} \right)^{(k+1)/2(k-1)}$$

Thus,

Ma	$k = 1.2$	$k = 1.4$	$k = 1.6$
0.0	0	0	0
0.1	0.1089	0.1176	0.1257
0.2	0.2143	0.2311	0.2465
0.3	0.3128	0.3365	0.3582
0.4	0.4015	0.4306	0.4571
0.5	0.4782	0.5111	0.5407
0.6	0.5411	0.5763	0.6077
0.7	0.5894	0.6257	0.6578
0.8	0.6230	0.6595	0.6916
0.9	0.6424	0.6787	0.7106
1.0	0.6485	0.6847	0.7164

Discussion Note that the mass flow rate increases with increasing Mach number and specific heat ratio. It levels off at $\text{Ma} = 1$, and remains constant (choked flow).

17-131 Helium gas is accelerated in a nozzle. The pressure and temperature of helium at the location where $\text{Ma} = 1$ and the ratio of the flow area at this location to the inlet flow area are to be determined.

Assumptions 1 Helium is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

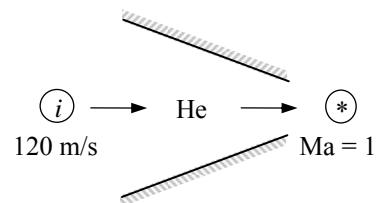

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.667$ (Table A-2a).

Analysis The properties of the fluid at the location where $\text{Ma} = 1$ are the critical properties, denoted by superscript *. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 500 \text{ K} + \frac{(120 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 501.4 \text{ K}$$

and

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (0.8 \text{ MPa}) \left(\frac{501.4 \text{ K}}{500 \text{ K}} \right)^{1.667/(1.667-1)} = 0.806 \text{ MPa}$$

The Mach number at the nozzle exit is given to be $\text{Ma} = 1$. Therefore, the properties at the nozzle exit are the *critical properties* determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (501.4 \text{ K}) \left(\frac{2}{1.667+1} \right) = 376 \text{ K}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (0.806 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.393 \text{ MPa}$$

The speed of sound and the Mach number at the nozzle inlet are

$$c_i = \sqrt{kRT_i} = \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(500 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1316 \text{ m/s}$$

$$\text{Ma}_i = \frac{V_i}{c_i} = \frac{120 \text{ m/s}}{1316 \text{ m/s}} = 0.0912$$

The ratio of the entrance-to-throat area is

$$\begin{aligned} \frac{A_i}{A^*} &= \frac{1}{\text{Ma}_i} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} \text{Ma}_i^2 \right) \right]^{(k+1)/[2(k-1)]} \\ &= \frac{1}{0.0912} \left[\left(\frac{2}{1.667+1} \right) \left(1 + \frac{1.667-1}{2} (0.0912)^2 \right) \right]^{2.667/(2 \times 0.667)} \\ &= 6.20 \end{aligned}$$

Then the ratio of the throat area to the entrance area becomes

$$\frac{A^*}{A_i} = \frac{1}{6.20} = 0.161$$

Discussion The compressible flow functions are essential tools when determining the proper shape of the compressible flow duct.

17-132 Helium gas enters a nozzle with negligible velocity, and is accelerated in a nozzle. The pressure and temperature of helium at the location where $\text{Ma} = 1$ and the ratio of the flow area at this location to the inlet flow area are to be determined.

Assumptions 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The entrance velocity is negligible.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.667$ (Table A-2a).

Analysis We treat helium as an ideal gas with $k = 1.667$. The properties of the fluid at the location where $\text{Ma} = 1$ are the critical properties, denoted by superscript *.

The stagnation temperature and pressure in this case are identical to the inlet temperature and pressure since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i = 500 \text{ K}$$

$$P_0 = P_i = 0.8 \text{ MPa}$$

The Mach number at the nozzle exit is given to be $\text{Ma} = 1$. Therefore, the properties at the nozzle exit are the *critical properties* determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (500 \text{ K}) \left(\frac{2}{1.667+1} \right) = 375 \text{ K}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (0.8 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.390 \text{ MPa}$$

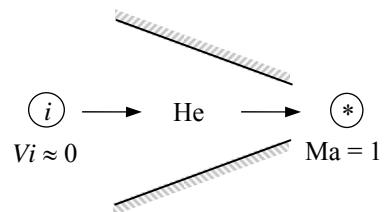

The ratio of the nozzle inlet area to the throat area is determined from

$$\frac{A_i}{A^*} = \frac{1}{\text{Ma}_i} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} \text{Ma}_i^2 \right) \right]^{(k+1)/[2(k-1)]}$$

But the Mach number at the nozzle inlet is $\text{Ma} = 0$ since $V_i \approx 0$. Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{\infty} = 0$$

Discussion The compressible flow functions are essential tools when determining the proper shape of the compressible flow duct.

17-133 Air enters a converging nozzle. The mass flow rate, the exit velocity, the exit Mach number, and the exit pressure-stagnation pressure ratio versus the back pressure-stagnation pressure ratio for a specified back pressure range are to be calculated and plotted.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

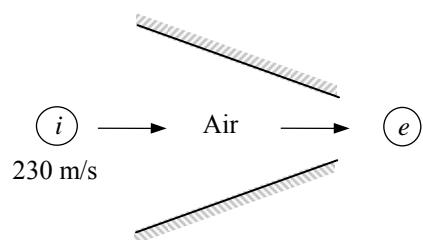

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The stagnation properties remain constant throughout the nozzle since the flow is isentropic. They are determined from

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 500 \text{ K} + \frac{(230 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 526.3 \text{ K}$$

and

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (900 \text{ kPa}) \left(\frac{526.3 \text{ K}}{500 \text{ K}} \right)^{1.4/(1.4-1)} = 1077 \text{ kPa}$$

The critical pressure is determined to be

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (1077 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/0.4} = 569.0 \text{ kPa}$$

Then the pressure at the exit plane (throat) will be

$$P_e = P_b \quad \text{for} \quad P_b \geq 569.0 \text{ kPa}$$

$$P_e = P^* = 569.0 \text{ kPa} \quad \text{for} \quad P_b < 569.0 \text{ kPa} \quad (\text{choked flow})$$

Thus the back pressure will not affect the flow when $100 < P_b < 569.0 \text{ kPa}$. For a specified exit pressure P_e , the temperature, the velocity and the mass flow rate can be determined from

$$\text{Temperature} \quad T_e = T_0 \left(\frac{P_e}{P_0} \right)^{(k-1)/k} = (526.3 \text{ K}) \left(\frac{P_e}{1077} \right)^{0.4/1.4}$$

$$\text{Velocity} \quad V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.005 \text{ kJ/kg}\cdot\text{K})(526.3 - T_e) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Speed of sound} \quad c_e = \sqrt{kRT_e} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Mach number} \quad \text{Ma}_e = V_e / c_e$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.001 \text{ m}^2)$$

17-134 Steam enters a converging nozzle. The exit pressure, the exit velocity, and the mass flow rate versus the back pressure for a specified back pressure range are to be plotted.

Assumptions 1 Steam is to be treated as an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The ideal gas properties of steam are given to be $R = 0.462 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.872 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.3$.

Analysis The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Since the flow is isentropic, they remain constant throughout the nozzle,

$$P_0 = P_i = 6 \text{ MPa}$$

$$T_0 = T_i = 700 \text{ K}$$

The critical pressure is determined from to be

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (6 \text{ MPa}) \left(\frac{2}{1.3+1} \right)^{1.3/0.3} = 3.274 \text{ MPa}$$

Then the pressure at the exit plane (throat) will be

$$P_e = P_b \quad \text{for} \quad P_b \geq 3.274 \text{ MPa}$$

$$P_e = P^* = 3.274 \text{ MPa} \quad \text{for} \quad P_b < 3.274 \text{ MPa} \quad (\text{choked flow})$$

Thus the back pressure will not affect the flow when $3 < P_b < 3.274 \text{ MPa}$. For a specified exit pressure P_e , the temperature, the velocity and the mass flow rate can be determined from

Temperature

$$T_e = T_0 \left(\frac{P_e}{P_0} \right)^{(k-1)/k} = (700 \text{ K}) \left(\frac{P_e}{6} \right)^{0.3/1.3}$$

Velocity

$$V_e = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.872 \text{ kJ/kg}\cdot\text{K})(700 - T_e) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

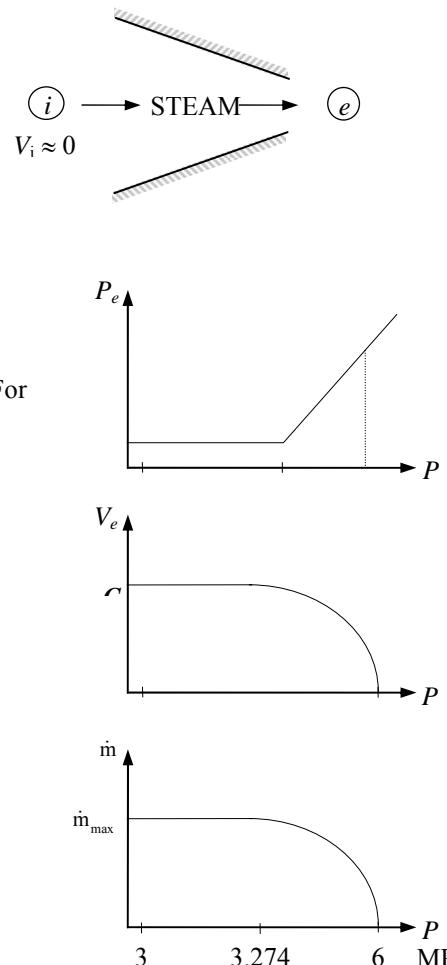

Density

$$\rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.462 \text{ kPa}\cdot\text{m}^3 / \text{kg}\cdot\text{K})T_e}$$

Mass flow rate

$$\dot{m} = \rho_e V_e A_e = \rho_e V_e (0.0008 \text{ m}^2)$$

The results of the calculations can be tabulated as follows:

$P_b, \text{ MPa}$	$P_e, \text{ MPa}$	$T_e, \text{ K}$	$V_e, \text{ m/s}$	$\rho_e, \text{ kg/m}^3$	$\dot{m}, \text{ kg/s}$
6.0	6.0	700	0	18.55	0

3.274	3.274	608.7	584.7	11.64	5.445
3.0	3.274	608.7	584.7	11.64	5.445

17-135 An expression for the ratio of the stagnation pressure after a shock wave to the static pressure before the shock wave as a function of k and the Mach number upstream of the shock wave is to be found.

Analysis The relation between P_1 and P_2 is

$$\frac{P_2}{P_1} = \frac{1+kMa_2^2}{1+kMa_1^2} \longrightarrow P_2 = P_1 \left(\frac{1+kMa_1^2}{1+kMa_2^2} \right)$$

Substituting this into the isentropic relation

$$\frac{P_{02}}{P_1} = \left(1 + (k-1)Ma_2^2 / 2 \right)^{k/(k-1)}$$

Then,

$$\frac{P_{02}}{P_1} = \left(\frac{1+kMa_1^2}{1+kMa_2^2} \right) \left(1 + (k-1)Ma_2^2 / 2 \right)^{k/(k-1)}$$

where

$$Ma_2^2 = \frac{Ma_1^2 + 2/(k-1)}{2kMa_2^2/(k-1) - 1}$$

Substituting,

$$\frac{P_{02}}{P_1} = \left(\frac{(1+kMa_1^2)(2kMa_1^2 - k + 1)}{kMa_1^2(k + 1) - k + 3} \right) \left(1 + \frac{(k-1)Ma_1^2 / 2 + 1}{2kMa_1^2 / (k-1) - 1} \right)^{k/(k-1)}$$

17-136 Nitrogen entering a converging-diverging nozzle experiences a normal shock. The pressure, temperature, velocity, Mach number, and stagnation pressure downstream of the shock are to be determined. The results are to be compared to those of air under the same conditions.

Assumptions 1 Nitrogen is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The properties of nitrogen are $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Assuming the flow before the shock to be isentropic,

$$\begin{aligned} P_{01} &= P_i = 700 \text{ kPa} \\ T_{01} &= T_i = 300 \text{ K} \\ V_i &\approx 0 \end{aligned}$$

Then,

$$T_1 = T_{01} \left(\frac{2}{2 + (k-1)Ma_1^2} \right) = (300 \text{ K}) \left(\frac{2}{2 + (1.4-1)3^2} \right) = 107.1 \text{ K}$$

and

$$P_1 = P_{01} \left(\frac{T_1}{T_{01}} \right)^{k/(k-1)} = (700 \text{ kPa}) \left(\frac{107.1}{300} \right)^{1.4/0.4} = 19.06 \text{ kPa}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $Ma_1 = 3.0$ we read

$$Ma_2 = 0.4752, \frac{P_{02}}{P_{01}} = 0.32834, \frac{P_2}{P_1} = 10.333, \text{ and } \frac{T_2}{T_1} = 2.679$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 0.32834 P_{01} = (0.32834)(700 \text{ kPa}) = 230 \text{ kPa}$$

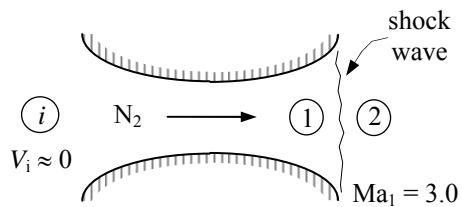

$$P_2 = 10.333 P_1 = (10.333)(19.06 \text{ kPa}) = 197 \text{ kPa}$$

$$T_2 = 2.679 T_1 = (2.679)(107.1 \text{ K}) = 287 \text{ K}$$

The velocity after the shock can be determined from $V_2 = Ma_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = Ma_2 c_2 = Ma_2 \sqrt{kRT_2} = (0.4752) \sqrt{(1.4)(0.2968 \text{ kJ/kg}\cdot\text{K})(287 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 164 \text{ m/s}$$

Discussion For air at specified conditions $k = 1.4$ (same as nitrogen) and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Thus the only quantity which will be different in the case of air is the velocity after the normal shock, which happens to be 161.3 m/s.

17-137 The diffuser of an aircraft is considered. The static pressure rise across the diffuser and the exit area are to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the diffuser is steady, one-dimensional, and isentropic. 3 The diffuser is adiabatic.

Properties Air properties at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The inlet velocity is

$$V_1 = Ma_1 c_1 = M_1 \sqrt{kRT_1} = (0.7) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(242.7 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 218.6 \text{ m/s}$$

Then the stagnation temperature and pressure at the diffuser inlet become

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 242.7 + \frac{(218.6 \text{ m/s})^2}{2(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 266.5 \text{ K}$$

$$P_{01} = P_1 \left(\frac{T_{01}}{T_1} \right)^{k/(k-1)} = (41.1 \text{ kPa}) \left(\frac{266.5 \text{ K}}{242.7 \text{ K}} \right)^{1.4/(1.4-1)} = 57.0 \text{ kPa}$$

For an adiabatic diffuser, the energy equation reduces to $h_{01} = h_{02}$. Noting that $h = c_p T$ and the specific heats are assumed to be constant, we have

$$T_{01} = T_{02} = T_0 = 266.5 \text{ K}$$

The isentropic relation between states 1 and 02 gives

$$P_{02} = P_1 \left(\frac{T_{02}}{T_1} \right)^{k/(k-1)} = (41.1 \text{ kPa}) \left(\frac{266.5 \text{ K}}{242.7 \text{ K}} \right)^{1.4/(1.4-1)} = 55.59 \text{ kPa}$$

The exit velocity can be expressed as

$$V_2 = Ma_2 c_2 = Ma_2 \sqrt{kRT_2} = (0.25) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K}) T_2 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 5.01\sqrt{T_2}$$

$$\text{Thus, } T_2 = T_{02} - \frac{V_2^2}{2c_p} = (266.5) - \frac{5.01^2 T_2 \text{ m}^2/\text{s}^2}{2(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \longrightarrow T_2 = 263.2 \text{ K}$$

Then the static exit pressure becomes

$$P_2 = P_{02} \left(\frac{T_2}{T_{02}} \right)^{k/(k-1)} = (55.59 \text{ kPa}) \left(\frac{263.2 \text{ K}}{266.5 \text{ K}} \right)^{1.4/(1.4-1)} = 53.23 \text{ kPa}$$

Thus the static pressure rise across the diffuser is

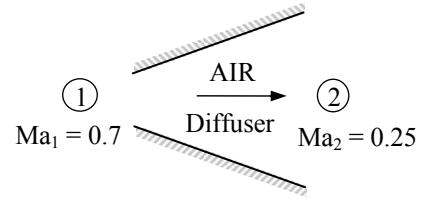

$$\Delta P = P_2 - P_1 = 53.23 - 41.1 = \mathbf{12.13 \text{ kPa}}$$

$$\text{Also, } \rho_2 = \frac{P_2}{RT_2} = \frac{53.23 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(263.2 \text{ K})} = 0.7047 \text{ kg/m}^3$$

$$V_2 = 6.01\sqrt{T_2} = 5.01\sqrt{263.2} = 81.3 \text{ m/s}$$

$$\text{Thus, } A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{30 \text{ kg/s}}{(0.7047 \text{ kg/m}^3)(81.3 \text{ m/s})} = \mathbf{0.524 \text{ m}^2}$$

Discussion The pressure rise in actual diffusers will be lower because of the irreversibilities. However, flow through well-designed diffusers is very nearly isentropic.

17-138 Helium gas is accelerated in a nozzle isentropically. For a specified mass flow rate, the throat and exit areas of the nozzle are to be determined.

Assumptions 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$, $k = 1.667$ (Table A-2a).

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible,

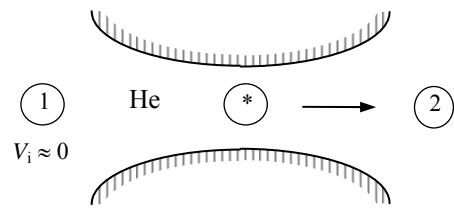

$$T_{01} = T_1 = 500 \text{ K}$$

$$P_{01} = P_1 = 1.0 \text{ MPa}$$

The flow is assumed to be isentropic, thus the stagnation temperature and pressure remain constant throughout the nozzle,

$$T_{02} = T_{01} = 500 \text{ K}$$

$$P_{02} = P_{01} = 1.0 \text{ MPa}$$

The critical pressure and temperature are determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (500 \text{ K}) \left(\frac{2}{1.667+1} \right) = 375.0 \text{ K}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (1.0 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.487 \text{ MPa}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{487 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(375 \text{ K})} = 0.625 \text{ kg/m}^3$$

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(375 \text{ K}) \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 1139.4 \text{ m/s}$$

Thus the throat area is

$$A^* = \frac{\dot{m}}{\rho^* V^*} = \frac{0.25 \text{ kg/s}}{(0.625 \text{ kg/m}^3)(1139.4 \text{ m/s})} = 3.51 \times 10^{-4} \text{ m}^2 = 3.51 \text{ cm}^2$$

At the nozzle exit the pressure is $P_2 = 0.1 \text{ MPa}$. Then the other properties at the nozzle exit are determined to be

$$\frac{P_0}{P_2} = \left(1 + \frac{k-1}{2} Ma_2^2 \right)^{k/(k-1)} \longrightarrow \frac{1.0 \text{ MPa}}{0.1 \text{ MPa}} = \left(1 + \frac{1.667-1}{2} Ma_2^2 \right)^{1.667/0.667}$$

It yields $Ma_2 = 2.130$, which is greater than 1. Therefore, the nozzle must be converging-diverging.

$$T_2 = T_0 \left(\frac{2}{2+(k-1)Ma_2^2} \right) = (500 \text{ K}) \left(\frac{2}{2+(1.667-1) \times 2.13^2} \right) = 199.0 \text{ K}$$

$$\rho_2 = \frac{P_2}{RT_2} = \frac{100 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(199 \text{ K})} = 0.242 \text{ kg/m}^3$$

$$V_2 = Ma_2 c_2 = Ma_2 \sqrt{kRT_2} = (2.13) \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(199 \text{ K}) \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 1768.0 \text{ m/s}$$

Thus the exit area is

$$A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{0.25 \text{ kg/s}}{(0.242 \text{ kg/m}^3)(1768 \text{ m/s})} = 5.84 \times 10^{-4} \text{ m}^2 = 5.84 \text{ cm}^2$$

Discussion Flow areas in actual nozzles would be somewhat larger to accommodate the irreversibilities.

17-139E Helium gas is accelerated in a nozzle. For a specified mass flow rate, the throat and exit areas of the nozzle are to be determined for the cases of isentropic and 97% efficient nozzles.

Assumptions 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The properties of helium are $R = 0.4961 \text{ Btu/lbm}\cdot\text{R}$, $c_p = 1.25 \text{ Btu/lbm}\cdot\text{R}$, and $k = 1.667$ (Table A-2Ea).

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible,

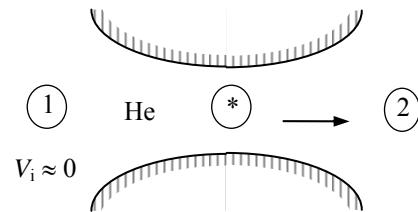

$$T_{01} = T_i = 900 \text{ R}$$

$$P_{01} = P_i = 150 \text{ psia}$$

The flow is assumed to be isentropic, thus the stagnation temperature and pressure remain constant throughout the nozzle,

$$T_{02} = T_{01} = 900 \text{ R}$$

$$P_{02} = P_{01} = 150 \text{ psia}$$

The critical pressure and temperature are determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (900 \text{ R}) \left(\frac{2}{1.667+1} \right) = 674.9 \text{ R}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (150 \text{ psia}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 73.1 \text{ psia}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{73.1 \text{ psia}}{(2.6809 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(674.9 \text{ R})} = 0.04041 \text{ lbm}/\text{ft}^3$$

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(674.9 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 3738 \text{ ft/s}$$

$$\text{and } A^* = \frac{\dot{m}}{\rho^* V^*} = \frac{0.21 \text{ lbm/s}}{(0.04041 \text{ lbm}/\text{ft}^3)(3738 \text{ ft/s})} = \mathbf{0.00132 \text{ ft}^2}$$

At the nozzle exit the pressure is $P_2 = 15 \text{ psia}$. Then the other properties at the nozzle exit are determined to be

$$\frac{p_0}{p_2} = \left(1 + \frac{k-1}{2} Ma_2^2 \right)^{k/(k-1)} \longrightarrow \frac{15 \text{ psia}}{15 \text{ psia}} = \left(1 + \frac{1.667-1}{2} Ma_2^2 \right)^{1.667/0.667}$$

It yields $Ma_2 = 2.130$, which is greater than 1. Therefore, the nozzle must be converging-diverging.

$$T_2 = T_0 \left(\frac{2}{2+(k-1)Ma_2^2} \right) = (900 \text{ R}) \left(\frac{2}{2+(1.667-1) \times 2.13^2} \right) = 358.1 \text{ R}$$

$$\rho_2 = \frac{P_2}{RT_2} = \frac{15 \text{ psia}}{(2.6809 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(358.1 \text{ R})} = 0.01561 \text{ lbm}/\text{ft}^3$$

$$V_2 = Ma_2 c_2 = Ma_2 \sqrt{kRT_2} = (2.13) \sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(358.1 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 5800 \text{ ft/s}$$

Thus the exit area is

$$A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{0.2 \text{ lbm/s}}{(0.01561 \text{ lbm}/\text{ft}^3)(5800 \text{ ft/s})} = \mathbf{0.00221 \text{ ft}^2}$$

Discussion Flow areas in actual nozzles would be somewhat larger to accommodate the irreversibilities.

17-140 Using the compressible flow relations, the one-dimensional compressible flow functions are to be evaluated and tabulated as in Table A-32 for an ideal gas with $k = 1.667$.

Properties The specific heat ratio of the ideal gas is given to be $k = 1.667$.

Analysis The compressible flow functions listed below are expressed in EES and the results are tabulated.

$$\text{Ma}^* = \text{Ma} \sqrt{\frac{k+1}{2+(k-1)\text{Ma}^2}}$$

$$\frac{A}{A^*} = \frac{1}{\text{Ma}} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} \text{Ma}^2 \right) \right]^{0.5(k+1)/(k-1)}$$

$$\frac{P}{P_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-k/(k-1)}$$

$$\frac{\rho}{\rho_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1/(k-1)}$$

$$\frac{T}{T_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1}$$

$k=1.667$

$\text{PP0}=(1+(k-1)*\text{M}^2/2)^{(-k/(k-1))}$

$\text{TT0}=1/(1+(k-1)*\text{M}^2/2)$

$\text{DD0}=(1+(k-1)*\text{M}^2/2)^{(-1/(k-1))}$

$\text{Mcr}=\text{M}*\text{SQRT}((k+1)/(2+(k-1)*\text{M}^2))$

$\text{AAcr}=((2/(k+1))*(1+0.5*(k-1)*\text{M}^2))^{(0.5*(k+1)/(k-1))/\text{M}}$

17-142 The critical temperature, pressure, and density of an equimolar mixture of oxygen and nitrogen for specified stagnation properties are to be determined.

Assumptions Both oxygen and nitrogen are ideal gases with constant specific heats at room temperature.

Properties The specific heat ratio and molar mass are $k = 1.395$ and $M = 32 \text{ kg/kmol}$ for oxygen, and $k = 1.4$ and $M = 28 \text{ kg/kmol}$ for nitrogen (Tables A-1 and A-2).

Analysis The gas constant of the mixture is

$$M_m = y_{O_2} M_{O_2} + y_{N_2} M_{N_2} = 0.5 \times 32 + 0.5 \times 28 = 30 \text{ kg/kmol}$$

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{30 \text{ kg/kmol}} = 0.2771 \text{ kJ/kg} \cdot \text{K}$$

The specific heat ratio is 1.4 for nitrogen, and nearly 1.4 for oxygen. Therefore, the specific heat ratio of the mixture is also 1.4. Then the critical temperature, pressure, and density of the mixture become

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (600 \text{ K}) \left(\frac{2}{1.4+1} \right) = \mathbf{500.0 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (300 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{158.5 \text{ kPa}}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{158.5 \text{ kPa}}{(0.2771 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(500 \text{ K})} = \mathbf{1.144 \text{ kg/m}^3}$$

Discussion If the specific heat ratios k of the two gases were different, then we would need to determine the k of the mixture from $k = c_{p,m}/c_{v,m}$ where the specific heats of the mixture are determined from

$$c_{p,m} = mf_{O_2} c_{p,O_2} + mf_{N_2} c_{p,N_2} = (y_{O_2} M_{O_2} / M_m) c_{p,O_2} + (y_{N_2} M_{N_2} / M_m) c_{p,N_2}$$

$$c_{v,m} = mf_{O_2} c_{v,O_2} + mf_{N_2} c_{v,N_2} = (y_{O_2} M_{O_2} / M_m) c_{v,O_2} + (y_{N_2} M_{N_2} / M_m) c_{v,N_2}$$

where mf is the mass fraction and y is the mole fraction. In this case it would give

$$c_{p,m} = (0.5 \times 32 / 30) \times 0.918 + (0.5 \times 28 / 30) \times 1.039 = 0.9745 \text{ kJ/kg.K}$$

$$c_{v,m} = (0.5 \times 32 / 30) \times 0.658 + (0.5 \times 28 / 30) \times 0.743 = 0.6977 \text{ kJ/kg.K}$$

and

$$k = 0.9745 / 0.6977 = 1.397$$

17-143 Using EES (or other) software, the shape of a converging-diverging nozzle is to be determined for specified flow rate and stagnation conditions. The nozzle and the Mach number are to be plotted.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

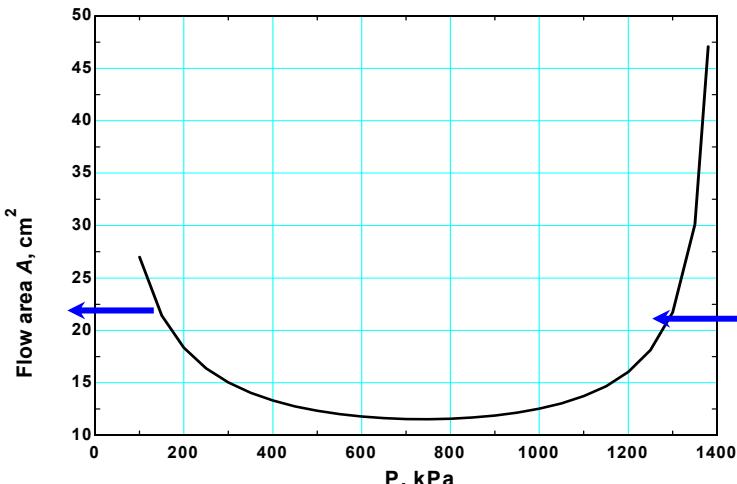

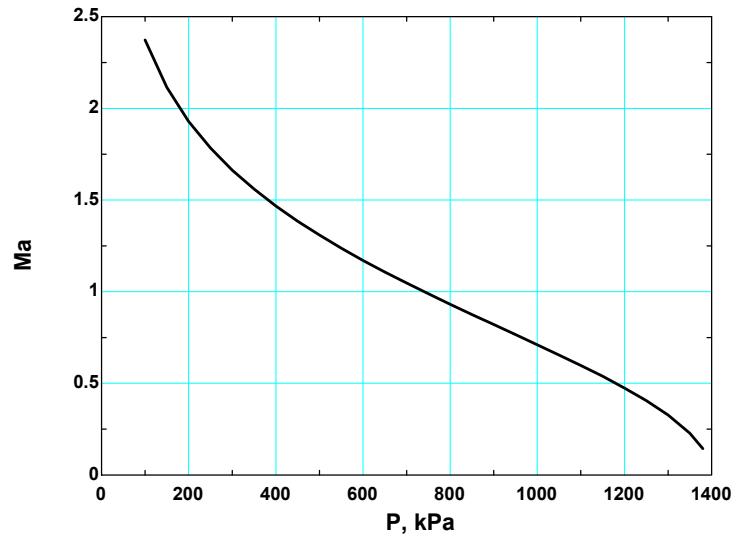

Properties The specific heat ratio of air at room temperature is 1.4 (Table A-2a).

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

```

17-148 Air flowing at a supersonic velocity in a duct is accelerated by cooling. For a specified exit Mach number, the rate of heat transfer is to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Knowing stagnation properties, the static properties are determined to be

$$T_1 = T_{01} \left(1 + \frac{k-1}{2} Ma_1^2 \right)^{-1} = (350 \text{ K}) \left(1 + \frac{1.4-1}{2} 1.2^2 \right)^{-1} = 271.7 \text{ K}$$

$$P_1 = P_{01} \left(1 + \frac{k-1}{2} Ma_1^2 \right)^{-k/(k-1)} = (240 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 1.2^2 \right)^{-1.4/0.4} = 98.97 \text{ kPa}$$

$$\rho_1 = \frac{P_1}{RT_1} = \frac{98.97 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(271.7 \text{ K})} = 1.269 \text{ kg/m}^3$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(271.7 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 330.4 \text{ m/s}$$

$$V_1 = Ma_1 c_1 = 1.2(330.4 \text{ m/s}) = 396.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{\text{cl}} V_1 = (1.269 \text{ kg/m}^3)[\pi(0.20 \text{ m})^2 / 4](330.4 \text{ m/s}) = 15.81 \text{ kg/s}$$

The Rayleigh flow functions T_0/T_0^* corresponding to the inlet and exit Mach numbers are (Table A-34):

$$Ma_1 = 1.8: \quad T_{01}/T_0^* = 0.9787$$

$$Ma_2 = 2: \quad T_{02}/T_0^* = 0.7934$$

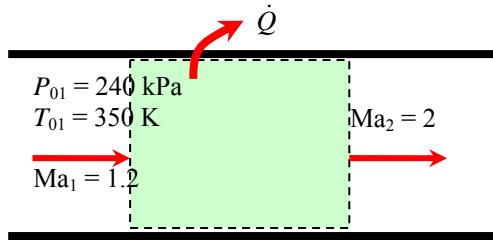

Then the exit stagnation temperature is determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{0.7934}{0.9787} = 0.8107 \rightarrow T_{02} = 0.8107 T_{01} = 0.8107(350 \text{ K}) = 283.7 \text{ K}$$

Finally, the rate of heat transfer is

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (15.81 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(283.7 - 350) \text{ K} = -1053 \text{ kW}$$

Discussion The negative sign confirms that the gas needs to be cooled in order to be accelerated. Also, it can be shown that the thermodynamic temperature drops to 158 K at the exit, which is extremely low. Therefore, the duct may need to be heavily insulated to maintain indicated flow conditions.

17-149 Air flowing at a subsonic velocity in a duct is accelerated by heating. The highest rate of heat transfer without affecting the inlet conditions is to be determined.

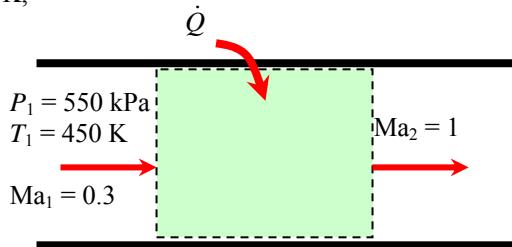

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Inlet conditions (and thus the mass flow rate) remain constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Heat transfer will stop when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. The inlet density and stagnation temperature are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{550 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(450 \text{ K})} = 4.259 \text{ kg/m}^3$$

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (450 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.3^2 \right) = 458.1 \text{ K}$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(450 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 425.2 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 0.3(425.2 \text{ m/s}) = 127.6 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (4.259 \text{ kg/m}^3)(0.08 \times 0.08 \text{ m}^2)(127.6 \text{ m/s}) = 3.477 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \text{ (since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2[2+(k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.4+1)0.3^2[2+(1.4-1)0.3^2]}{(1+1.4 \times 0.3^2)^2} = 0.3469 \text{ Ther}$$

efore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.3469} \rightarrow T_{02} = T_{01}/0.3469 = (458.1 \text{ K})/0.3469 = 1320.7 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (3.477 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1320.7 - 458.1) \text{ K} = \mathbf{3014 \text{ kW}}$$

Discussion It can also be shown that $T_2 = 1101 \text{ K}$, which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. We can also solve this problem using the Rayleigh function values listed in Table A-34.

17-150 Helium flowing at a subsonic velocity in a duct is accelerated by heating. The highest rate of heat transfer without affecting the inlet conditions is to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Inlet conditions (and thus the mass flow rate) remain constant.

Properties We take the properties of helium to be

$k = 1.667$, $c_p = 5.193 \text{ kJ/kg}\cdot\text{K}$, and $R = 2.077 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Heat transfer will stop when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. The inlet density and stagnation temperature are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{550 \text{ kPa}}{(2.077 \text{ kJ/kg}\cdot\text{K})(450 \text{ K})} = 0.5885 \text{ kg/m}^3$$

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (450 \text{ K}) \left(1 + \frac{1.667-1}{2} 0.3^2 \right) = 463.5 \text{ K}$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.667)(2.077 \text{ kJ/kg}\cdot\text{K})(450 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1248 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 0.3(1248 \text{ m/s}) = 374.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (0.5885 \text{ kg/m}^3)(0.08 \times 0.08 \text{ m}^2)(374.5 \text{ m/s}) = 1.410 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \text{ (since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2[2+(k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.667+1)0.33^2[2+(1.667-1)0.3^2]}{(1+1.667 \times 0.3^2)^2} = 0.3739$$

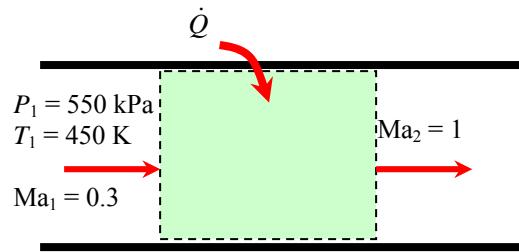

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.3739} \rightarrow T_{02} = T_{01}/0.3739 = (463.5 \text{ K})/0.3739 = 1239.8 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (1.410 \text{ kg/s})(5.193 \text{ kJ/kg}\cdot\text{K})(1239.8 - 463.5) \text{ K} = \mathbf{5685 \text{ kW}}$$

Discussion It can also be shown that $T_2 = 930 \text{ K}$, which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. Also, in the solution of this problem, we cannot use the values of Table A-34 since they are based on $k = 1.4$.

17-151 Air flowing at a subsonic velocity in a duct is accelerated by heating. For a specified exit Mach number, the heat transfer for a specified exit Mach number as well as the maximum heat transfer are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. **2** Inlet conditions (and thus the mass flow rate) remain constant.

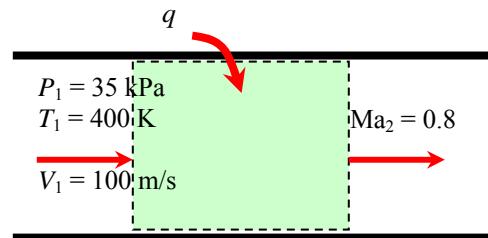

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis The inlet Mach number and stagnation temperature are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(400 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = 400.9 \text{ m/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{100 \text{ m/s}}{400.9 \text{ m/s}} = 0.2494$$

$$\begin{aligned} T_{01} &= T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) \\ &= (400 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.2494^2 \right) \\ &= 405.0 \text{ K} \end{aligned}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.2494: \quad T_{01}/T^* = 0.2559$$

$$\text{Ma}_2 = 0.8: \quad T_{02}/T^* = 0.9639$$

Then the exit stagnation temperature and the heat transfer are determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{0.9639}{0.2559} = 3.7667 \rightarrow T_{02} = 3.7667 T_{01} = 3.7667(405.0 \text{ K}) = 1526 \text{ K}$$

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(1526 - 405) \text{ K} = \mathbf{1126 \text{ kJ/kg}}$$

Maximum heat transfer will occur when the flow is choked, and thus $\text{Ma}_2 = 1$ and thus $T_{02}/T^* = 1$. Then,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{1}{0.2559} \rightarrow T_{02} = T_{01}/0.2559 = 405.0 \text{ K}/0.2559 = 1583 \text{ K}$$

$$q_{\max} = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(1583 - 405) \text{ K} = \mathbf{1184 \text{ kJ/kg}}$$

Discussion This is the maximum heat that can be transferred to the gas without affecting the mass flow rate. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease.

17-152 Air flowing at sonic conditions in a duct is accelerated by cooling. For a specified exit Mach number, the amount of heat transfer per unit mass is to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Noting that $\text{Ma}_1 = 1$, the inlet stagnation temperature is

$$\begin{aligned} T_{01} &= T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) \\ &= (500 \text{ K}) \left(1 + \frac{1.4-1}{2} 1^2 \right) = 600 \text{ K} \end{aligned}$$

The Rayleigh flow functions T_0/T_0^* corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1: \quad T_{01}/T_0^* = 1$$

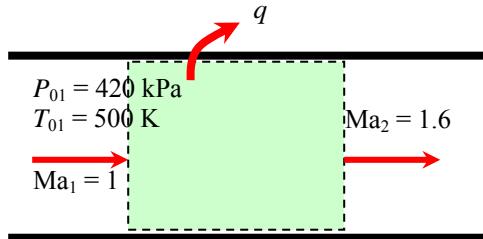

$$\text{Ma}_2 = 1.6: \quad T_{02}/T_0^* = 0.8842$$

Then the exit stagnation temperature and heat transfer are determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{0.8842}{1} = 0.8842 \quad \rightarrow \quad T_{02} = 0.8842 T_{01} = 0.8842(600 \text{ K}) = 530.5 \text{ K}$$

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(530.5 - 600) \text{ K} = -69.8 \text{ kJ/kg}$$

Discussion The negative sign confirms that the gas needs to be cooled in order to be accelerated. Also, it can be shown that the thermodynamic temperature drops to 351 K at the exit

17-153 Saturated steam enters a converging-diverging nozzle with a low velocity. The throat area, exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

Assumptions 1 Flow through the nozzle is steady and one-dimensional.

2 The nozzle is adiabatic.

Analysis (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{10} = h_1$. At the inlet,

$$h_1 = (h_f + x_1 h_{fg})_{@1.75 \text{ MPa}} = 878.16 + 0.90 \times 1917.1 = 2603.5 \text{ kJ/kg}$$

$$s_1 = (s_f + x_1 s_{fg})_{@1.75 \text{ MPa}} = 2.3844 + 0.90 \times 4.0033 = 5.9874 \text{ kJ/kg}\cdot\text{K}$$

At the exit, $P_2 = 1.2 \text{ MPa}$ and $s_2 = s_{2s} = s_1 = 5.9874 \text{ kJ/kg}\cdot\text{K}$. Thus,

$$s_2 = s_f + x_2 s_{fg} \rightarrow 5.9874 = 2.2159 + x_2(4.3058) \rightarrow x_2 = 0.8759$$

$$h_2 = h_f + x_2 h_{fg} = 798.33 + 0.8759 \times 1985.4 = 2537.4 \text{ kJ/kg}$$

$$\nu_2 = \nu_f + x_2 \nu_{fg} = 0.001138 + 0.8759 \times (0.16326 - 0.001138) = 0.14314 \text{ m}^3/\text{kg}$$

Then the exit velocity is determined from the steady-flow energy balance to be

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} \rightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(2603.5 - 2537.4) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 363.7 \text{ m/s}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{\nu_2} A_2 V_2 = \frac{1}{0.14314 \text{ m}^3/\text{kg}} (25 \times 10^{-4} \text{ m}^2)(363.7 \text{ m/s}) = 6.35 \text{ kg/s}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \sigma} \right)_s^{1/2} \approx \left(\frac{\Delta P}{\Delta(1/\nu)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 5.9874 \text{ kJ/kg}\cdot\text{K}$ and at pressures just below and just above the specified pressure (1.1 and 1.3 MPa) are determined to be 0.1547 and 0.1333 m^3/kg . Substituting,

$$c_2 = \sqrt{\left(\frac{(1300 - 1100) \text{ kPa}}{\frac{1}{0.1333} - \frac{1}{0.1547}} \right) \text{ kg/m}^3 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 438.9 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{363.7 \text{ m/s}}{438.9 \text{ m/s}} = 0.829$$

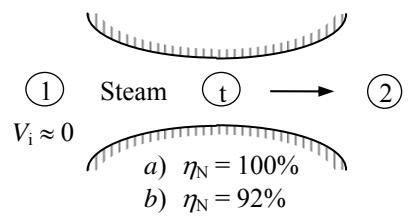

The steam is saturated, and thus the critical pressure which occurs at the throat is taken to be

$$P_t = P^* = 0.576 \times P_{01} = 0.576 \times 1.75 = 1.008 \text{ MPa}$$

Then at the throat,

$$P_t = 1.008 \text{ MPa} \text{ and } s_t = s_1 = 5.9874 \text{ kJ/kg}\cdot\text{K}$$

Thus,

$$h_t = 2507.7 \text{ kJ/kg}$$

$$\nu_t = 0.1672 \text{ m}^3 / \text{kg}$$

Then the throat velocity is determined from the steady-flow energy balance,

$$h_l + \frac{V_1^2}{2} = h_t + \frac{V_t^2}{2} \rightarrow 0 = h_t - h_l + \frac{V_t^2}{2}$$

Solving for V_t ,

$$V_t = \sqrt{2(h_t - h_l)} = \sqrt{2(2603.5 - 2507.7) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = 437.7 \text{ m/s}$$

Thus the throat area is

$$A_t = \frac{\dot{m} \nu_t}{V_t} = \frac{(6.35 \text{ kg/s})(0.1672 \text{ m}^3 / \text{kg})}{437.7 \text{ m/s}} = 24.26 \times 10^{-4} \text{ m}^2 = \mathbf{24.26 \text{ cm}^2}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{10} = h_1$. At the inlet,

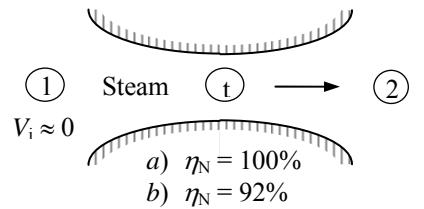

$$h_1 = (h_f + x_1 h_{fg})_{@1.75 \text{ MPa}} = 878.16 + 0.90 \times 1917.1 = 2603.5 \text{ kJ/kg}$$

$$s_1 = (s_f + x_1 s_{fg})_{@1.75 \text{ MPa}} = 2.3844 + 0.90 \times 4.0033 = 5.9874 \text{ kJ/kg}\cdot\text{K}$$

At state 2s, $P_2 = 1.2 \text{ MPa}$ and $s_2 = s_{2s} = s_1 = 5.9874 \text{ kJ/kg}\cdot\text{K}$. Thus,

$$s_{2s} = s_f + x_2 s_{fg} \rightarrow 5.9874 = 2.2159 + x_2(4.3058) \rightarrow x_{2s} = 0.8759$$

$$h_{2s} = h_f + x_2 h_{fg} = 798.33 + 0.8759 \times 1985.4 = 2537.4 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.92 = \frac{2603.5 - h_2}{2603.4 - 2537.4} \longrightarrow h_2 = 2542.7 \text{ kJ/kg}$$

Therefore at the exit, $P_2 = 1.2 \text{ MPa}$ and $h_2 = 2542.7 \text{ kJ/kg}\cdot\text{K}$. Thus,

$$h_2 = h_f + x_2 h_{fg} \longrightarrow 2542.7 = 798.33 + x_2(1985.4) \longrightarrow x_2 = 0.8786$$

$$s_2 = s_f + x_2 s_{fg} = 2.2159 + 0.8786 \times 4.3058 = 5.9989$$

$$\nu_2 = \nu_f + x_2 \nu_{fg} = 0.001138 + 0.8786 \times (0.16326 - 0.001138) = 0.1436 \text{ kg/m}^3$$

Then the exit velocity is determined from the steady-flow energy balance to be

$$h_l + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} \rightarrow 0 = h_2 - h_l + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_l - h_2)} = \sqrt{2(2603.5 - 2542.7) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{348.9 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{\nu_2} A_2 V_2 = \frac{1}{0.1436 \text{ m}^3 / \text{kg}} (25 \times 10^{-4} \text{ m}^2)(348.9 \text{ m/s}) = \mathbf{6.07 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left(\frac{\Delta P}{\Delta(1/\nu)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 5.9989 \text{ kJ/kg}\cdot\text{K}$ and at pressures just below and just above the specified pressure (1.1 and 1.3 MPa) are determined to be 0.1551 and $0.1337 \text{ m}^3/\text{kg}$. Substituting,

$$c_2 = \sqrt{\frac{(1300 - 1100)\text{kPa}}{\left(\frac{1}{0.1337} - \frac{1}{0.1551}\right)\text{kg/m}^3} \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kPa} \cdot \text{m}^3}\right)} = 439.7 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{348.9 \text{ m/s}}{439.7 \text{ m/s}} = \mathbf{0.793}$$

The steam is saturated, and thus the critical pressure which occurs at the throat is taken to be

$$P_t = P^* = 0.576 \times P_{01} = 0.576 \times 1.75 = 1.008 \text{ MPa}$$

At state 2ts, $P_{ts} = 1.008 \text{ MPa}$ and $s_{ts} = s_1 = 5.9874 \text{ kJ/kg}\cdot\text{K}$. Thus, $h_{ts} = 2507.7 \text{ kJ/kg}$.

The actual enthalpy of steam at the throat is

$$\eta_N = \frac{h_{01} - h_t}{h_{01} - h_{ts}} \longrightarrow 0.92 = \frac{2603.5 - h_t}{2603.5 - 2507.7} \longrightarrow h_t = 2515.4 \text{ kJ/kg}$$

Therefore at the throat, $P_2 = 1.008 \text{ MPa}$ and $h_t = 2515.4 \text{ kJ/kg}$. Thus, $\nu_t = 0.1679 \text{ m}^3/\text{kg}$.

Then the throat velocity is determined from the steady-flow energy balance,

$$h_l + \frac{V_1^{2,0}}{2} = h_t + \frac{V_t^2}{2} \rightarrow 0 = h_t - h_l + \frac{V_t^2}{2}$$

Solving for V_t ,

$$V_t = \sqrt{2(h_l - h_t)} = \sqrt{2(2603.5 - 2515.4)\text{kJ/kg} \left(\frac{1000 \text{ m}^2 / \text{s}^2}{1 \text{ kJ/kg}}\right)} = 419.9 \text{ m/s}$$

Thus the throat area is

$$A_t = \frac{\dot{m}V_t}{V_t} = \frac{(6.07 \text{ kg/s})(0.1679 \text{ m}^3 / \text{kg})}{419.9 \text{ m/s}} = 24.30 \times 10^{-4} \text{ m}^2 = \mathbf{24.30 \text{ cm}^2}$$

Fundamentals of Engineering (FE) Exam Problems

17-154 An aircraft is cruising in still air at 5°C at a velocity of 400 m/s. The air temperature at the nose of the aircraft where stagnation occurs is

- (a) 5°C (b) 25°C (c) 55°C (d) 80°C (e) 85°C

Answer (e) 85°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

17-162 Consider gas flow through a converging-diverging nozzle. Of the five statements below, select the one that is incorrect:

- (a) The fluid velocity at the throat can never exceed the speed of sound.
- (b) If the fluid velocity at the throat is below the speed of sound, the diversion section will act like a diffuser.
- (c) If the fluid enters the diverging section with a Mach number greater than one, the flow at the nozzle exit will be supersonic.
- (d) There will be no flow through the nozzle if the back pressure equals the stagnation pressure.
- (e) The fluid velocity decreases, the entropy increases, and stagnation enthalpy remains constant during flow through a normal shock.

Answer (c) If the fluid enters the diverging section with a Mach number greater than one, the flow at the nozzle exit will be supersonic.

17-163 Combustion gases with $k = 1.33$ enter a converging nozzle at stagnation temperature and pressure of 350°C and 400 kPa , and are discharged into the atmospheric air at 20°C and 100 kPa . The lowest pressure that will occur within the nozzle is

- (a) 13 kPa (b) 100 kPa (c) 216 kPa (d) 290 kPa (e) 315 kPa

Answer (c) 216 kPa

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

$k=1.33$
